A. ophthalmica *Moore* I can identify neither from the description nor from CONTE's figure, but it belongs *ophthal-* *mica*. to this group. Forewing dark red-brown, both the transverse stripes black, the anterior one indistinct, irregularly sinuately angled, the posterior one almost straight, from the apex; the large oval discal spot outside with a dent, bordered with black, the light subterminal line undulate-dentate. Hindwing of a brighter red-brown, base and margins light yellow, the very large black ocellus with a yellow ring, with a yellowish pupil being outside extended into 2 fine points and enclosing a white angular bar, behind it a black undulate line. Expanse of wings: 13 mm in the ♀. Brazil. Larva described to be black with long severely burning light brown thorns with black tips. It is said to live on an Iris near S. Paulo.

A. antioquia *Schs.* Head and thorax cinnamon-brown, abdomen above pink, beneath yellow, forewing *antioquia*. red-brown, strewn with yellow, with a white basal streak and a deep yellow antemedian line, distally scaled blackish with 3 white dots therein; discal spot dark brown, inside bordered by a straight yellow line, outside notched with 3 black dots; postmedian line from near the apex to the centre of the inner margin, outside red-brown, inside white with intense white vein-dots. Hindwing of a brilliant pink with a very large steel-grey ocellus being broadly encircled by black, then finely by yellow and white, pupil black, dusted white with a curved white line, above bordered by a brownish-yellow angular line; the black subterminal line is deeply undulate with a broad red-brown shadowy band behind it, the light pink marginal area with yellow veins, fringe yellow. Expanse of wings: 97 mm. According to a ♂ from Colombia (Dept. of Antioquia), before me e Coll. NIEPELT from Bellavista (Western Colombia).

A. fimbridentata *Dogn.* (111 e) resembles *hübneri* in the main characters and is easily discernible by *fimbriden-* *tata*. the dentate and somewhat speckled fringe. Forewing brown, strewn with red-brown, the transverse stripes are dotted white on the veins, and on the inverted sides somewhat white, subterminally with a series of small dentate nebulous spots. Hindwing pinkish claret-coloured, at the costal margin brown, towards the margin very light pink, the ocellus, as in all the species of this group, with a yellowish iris extended into 2 points. In the ♀ the margin is still more deeply dentate, apex of forewing more produced, hindwing browner. Peru.

A. grammivora *Jones* (111 c). Forewing ochreous or light reddish-brown with a very characteristic *grammi-* *vora*. yellow or yellowish-white postmedian line from the apex almost to the base of the inner margin, where it meets the indistinct antemedian line; discal spot entirely absent or marked by some dark dots. Hindwing pink with a large jet-black, yellow-ringed ocellus, a yellowish-grey iris with 3 or 4 fine points and a white crescentiform pupil; the undulate-dentate subterminal line is scaled deep blue, behind it a red-brown band. Brazil (Castro. Parana; Rio Grande do Sul).

A. grammodes *Jord.* (= *unifasciatus* *Bouv.*) (111 e). Forewing narrow, ochreous, scantily strewn with *grammodes*. dark; discal spot with a white pupil; from the pointed apex a black oblique line extends straight to $\frac{2}{5}$ of the inner margin, it is inwards bordered with yellow. Hindwing orange ochreous, towards the margin with a feeble pink tint, with a black, white-centred ocellus and a black line behind it, bending strongly basad at the inner

margin. The larger ♀ shows a distinctly brown-belted abdomen. South-Eastern Peru, Ecuador and Bolivia.

salmonea. **A. salmonea** Cr. By this name CRAMER figures two very different females which surely belong to different species. I have seen nothing similar to the figure 162 A, unless it be identified with *porus*. Forewing deep purple red-brown, without a distinct anterior transverse line, the posterior line black, ending about 8 mm before the apex, the discal spot surrounded by yellowish atoms and parted by the yellowish-dusted cross-vein. Hindwing red, the black ocellus surrounded by yellow, with a yellowish-grey horsehoe-shaped iris enclosing a black crescentiform pupil with a white angular streak; the black undulate line and the reddish-brown band behind it as in the other species of this group. Abdomen red, with dark carmine-brown bands. The figure supplied by CONTE as the ♂ of *salmonea* (Essai t. XII, fig. 3) does not fit at all the above mentioned figure by CRAMER, and I should much rather place it as ♂ to the following species which I consider to be *roseus* Conte.

roseus. **A. roseus** Conte (= *salmonea* Cr. pro parte, *arminirene* Strd.) (111 e). The figure in CRAMER 395 A represents a much lighter, more olive-brown species with a light brownish median area, the anterior transverse line is almost straight, very feebly S-curved, inwards broadly light yellowish, like the margin of the discal spot which terminates outside with 3 black-dotted points; the posterior transverse line meeting the anterior one at the inner margin is inside bordered with whitish, outside of it a somewhat darker subterminal band. Hindwing hued with pink, the ocellus similar to that of *salmonea*, but much more narrowly surrounded with yellowish-white, marginal area very light. Surinam. It may be *erubescens* Bsdv. This might be ascertained by comparing it with the type in the Paris Museum. Moreover, the species is variable and occurs in a more olive grey and a more red-brown form.

arminia. **A. arminia** Stoll. (= *hersilia* Bsdv.) resembles the above mentioned figure of *salmonea*, being just as dark carmine-brown, the black postmedian line marked on the veins by white scales, the discal spot entirely absent, the antemedian line marked at the inner margin by a small spot of yellowish scales. On the rosy-red hindwing the large ocellus is transversely oval, broadly surrounded by yellow, the very extensive iris brown, with a small white-strewn, black pupil enclosing a short white angular bar. Likewise from Surinam. It is difficult to ascertain from the figure whether this species really belongs hereto.

latus. **A. latus** Conte (= *sinuosa* Dogn., *brutus* Strd., *caesar* Bouv.) (111 c). Forewing of ♂ red-brown, yellowish-brown or olive-grey to lilac-grey, in the ♀ predominantly olive or lilac brown, the lines olive brown, forewing basally and at the costal margin somewhat darker; lines fine, posterior line between apex and the centre of the inner margin regular and very deeply undulate-dentate, discal spot rectangular with black dots around it. Hindwing lighter, only apically somewhat darker, with a very large ocellus surrounded by yellow and white, in the centre with a grey horseshoe-shaped spot finely extended into fine points on the veins and with a white angular line; behind the undulate-dentate subterminal line with a very broad brownish-red, in the ♀ olive band. A most variable species from Guiana, Amazons, Peru, Bolivia.

cruenta. **A. cruenta** Wkr. (111 A b). Forewing greyish-brown, the lower half of the basal area dark brown, bordered above by the lighter median vein, outside by an almost straight whitish transverse line, the posterior line pointedly broken below the costal margin, outside bordered by a darker shade, between both a blackish-brown discal spot; behind the subterminal line receding far between 3 and 5 the margin is darker; at the costal margin before the apex with a dark trapezoid spot. Hindwing very light greyish-brown, basally pink, ocellus and transverse lines as in the allies. Abdomen blackish with reddish-yellow segmental indentations. Brazil.

praecruenta. — **praecruenta** Weym. & W. was not before me; according to the figure it is very similar, darker, with more distinct and broader yellowish-white median and subcostal veins, the margin of the discal spot, as well as the postmedian and subterminal lines broader, too. Hindwing in the disc lighter, yellowish-white, the subterminal band much broader and darker. Abdomen with rosy-red bands. Rio de Janeiro. Hardly a different species.

convergens. **A. convergens** Wkr. (111 A b) is very similar to the two preceding species, forewing duller and more blurred, more reddish-brown, the light transverse lines very straight, at the inner margin almost contiguous, the discal spot very long and narrow, little darker than the ground. Hindwing more extensively rosy red, the black ocellus narrowly surrounded by yellowish-white. Abdomen curled ochreous. Brazil. — **semirosea** Weym. (111 A b) the type of which is before me seems to me to be merely a somewhat crippled *convergens* with narrow wings, with a more falcate apex; the marking in the much flown specimen likewise the same, only the posterior transverse line a little more curved, towards the margin deeper concave. South Brazil.

rubicunda. **A. rubicunda** Schs. (111 A b). Forewing above brown, in the basal area more reddish-yellow, bordered by a very fine dark transverse line; behind the cell an undulate-dentate transverse line, the oblong discal spot dark brown; at the costal margin near the apex a dark triangular spot. Hindwing above bright red with a small black ocellus with a brownish iris strewn with white in the centre; behind it a black transverse line and a brownish submarginal band, then a brownish marginal shadow in a lighter ground. Beneath the forewing

is yellow with a large black, white-centred spot, hindwing reddish-brown, strewn with black, with a white discal dot and a brown lunar line behind it. The brown metathorax with long projecting white hairs, abdomen reddish. Expanse of wings: 54 mm. Petropolis (Brazil).

A. flexuosa *Fldr.* (= ♀ *mendosa* *Bsdv.*, *bouvieri* *Conte*) (111 A c) is the ♂ of *mendosa* which is only known *flexuosa*. in the female. Forewing brown, in the basal area much lighter, reddish-grey, bordered by a fine black irregularly sinuate antemedian line; discal spot blackish, oblong; posterior transverse line towards the margin concave, undulate-dentate, the most intensely between 5 and 7, apically behind it a small dark triangular spot; fringe crossed by light on the ends of the veins. Hindwing rosy-red, at the margin light brownish, with a small, somewhat oblong ocellus, in the centre strewn with white, behind it a strong black line and then a brownish-red subterminal band. In the ♀ the forewing is whitish, strewn with yellowish-grey and black, the fine black transverse lines on the inverted sides bordered with whitish; the large brown discal spot surrounded by blackish, projecting outside in the middle; before the apex at the costal margin a brown triangular spot, behind the subterminal line the upper half of the margin is brownish, the lower half irregularly clouded whitish. Hindwing in the disc very pale pink, the fringe on the ends of the veins broad whitish. Rio de Janeiro to Argentina.

A. superba *Burm.* is somewhat similar, smaller, with an obtuse apex, below it on 6 somewhat roundedly *superba*. produced. Forewing basally and at the margin more darkened, only the median area light, otherwise similarly marked. Hindwing as in *flexuosa*. Argentina; Bolivia.

A. saturniata *Wkr.* (= *caesa* *Bsdv.*) (111 A c) is a large beautiful very characteristic species; forewing *saturniata*. on the whitish ground dusted and strewn with brown, the ground-colour being most distinct in the basal third of the costal margin, on the inverted sides of the transverse lines and in the subterminal line; transverse lines double, black, filled with ochreous, between them the large dark brown, four-pronged discal spot. Hindwing light brownish-grey, base and inner margin more or less rosy-red, behind the medium-sized ocellus with 3 blackish-grey nebulous bands; fringe crossed by bright yellowish white. Abdomen ochreous, curled black. Colombia (Bogota).

A. flexilineata *Dogn.* is allied to *saturniata*, easily separated by the strongly dentate posterior transverse *flexilineata*. line terminating into the apex; discal spot likewise quite similar; ground-colour more greenish-yellow, dusted with pinkish-black. Colombia (Paramo del Quindiu), described according to a ♂.

A. aurora *Maass.* is light yellowish-brown on the forewing, finely strewn with black and coarsely with *aurora*. red-brown, with 2 black curved transverse lines, the posterior one being slightly S-shaped and far remote from the margin, with a small black discal ring between them, and before the apex at the costal margin with a dark triangular spot, before which there are 2 small dark sagittiform spots marking the beginning of a subterminal line. Hindwing rosy-red with an oblong black ocellus being strewn with white in the centre, a black curved transverse line and a broader brownish band, behind which the marginal area is light brownish, with a darker marginal shadow. Abdomen pinkish-yellowish with small black triangular dorsal spots. Rio de Janeiro.

A. montezuma *Bsdv.* (= *crudelis* *Maass.*) (111 A c). Forewing brown, in the basal area and behind *montezuma*. the postmedian line darker, with almost straight black transverse lines bordered lighter on the inverted sides, an oblong discal spot and median shadow behind it; subterminal line light, from the apex, in the lower half projecting somewhat towards the margin. Hindwing rosy-red with a black, white-dusted ocellus; behind the black postmedian line the margin is brown with a darker subterminal band and marginal shadow. Abdomen crimson with blackish rings. Common from Mexico. Specimens from Guatemala and Costa Rica are smaller, lighter brownish, finely strewn, the median shadow almost entirely absent, the posterior transverse line more distinct, straighter, rather concave towards the margin, and at the costal margin more apicad: — **pallidior** *pallidior*. *f. n.* (111 A d); type in the Berlin Museum.

A. rectilinea *Bouv.* (111 A d) cannot be compared with any other species; body and forewing very light *rectilinea*. yellowish grey, strewn with brownish with 2 almost straight transverse lines of a brownish colour, on the inverted sides somewhat lighter owing to the absence of the strewing; at the cell-end a small narrow brownish spot; subterminal line absent. Hindwing brick-reddish, the large ocellus with an olive brown iris, with a velvety black ring and a large oval densely white-strewn pupil enclosing a thick white transverse bar; interior line blackish, somewhat undulate, the exterior line broader, brownish-red; fringe of hindwing red-brown. From Sao Paulo, in the Berlin Museum, another ♂ from Coll. GSCHWANDNER, the type in the Paris Museum.

A. iris *Wkr.* (111 A d). Forewing reddish greyish-brown, finely strewn darker, with blackish transverse *iris*. lines, the anterior one angularly receding below the cell, the posterior one almost straight, inside generally narrowly lighter, outside feebly darkened, the discal spot hardly darkened, marked by black dots, with a dark median streak; subterminal line composed of small spots. Hindwing orange, at the inner margin red, with a middle-sized ocellus, the black postmedian line behind it occasionally feebly undulate. Abdomen reddish-ochreous. Mexico. — **ferruginea** *f. n.* (111 A d) is somewhat smaller and shows a rusty brown ground-colour, *ferruginea* the hindwing being deeper orange, too. According to 2 ♂♂ from Mexico City, type in the Coll. DRAUDT. —

occidentalis. **occidentalis** f. n. (111 A d) are somewhat smaller greyer specimens from Western Mexico (Guerrero) with a somewhat more intense marking and a darker and more extensive red colour at the inner margin of the hindwing.
daudiana. — **daudiana** Drc. (111 A e) is very similar, the forewing light ash-grey, the marking otherwise the same, but the postmedian line is feebly convex towards the margin. Probably also only a form of it from Cuernavaca.

hebe. **A. hebe** Wkr. (= *thyreon* Dyar) (111 A c). Forewing reddish ochreous, basally and at the costal margin often somewhat darker, both the transverse lines as well as the subterminal line marked by small blackish lunular spots, the postmedian line almost straight, the slightly darker, mostly somewhat more ochreous discal spot marked by dark dots or also not. Hindwing ochreous, at the inner margin red, with a small black, white-centred ocellus, behind it a black, then a red-brown feebly undulate line. Abdomen dark ochreous. The ♀ has a deep purple brown ground-colour, the small lunular spots of the transverse lines on the inverted sides bordered with greyish-white. Mexico. CONTE mixed *hebe* with *orestes* Bsd., which is impossible, WALKER'S description exactly fits that of *thyreon*-♀ which is very variable.

melmon. **A. melmon** Dyar. Somewhat larger than *hebe*. Both the sexes show a somewhat sharper apex of the forewing. Ground-colour of ♂ yellow, the macular lines brownish-grey, the two exterior ones almost straight, the interior one only traceable. In the pinkish-brown ♀ the transverse lines are only feebly marked by whitish scales. Hindwing as in *hebe*. Expanse of wings: ♂ 51 mm, ♀ 56 mm. Mexico. — **dandemon** Dyar (111 A c) exactly resembles *melmon*, but the shape of the wings is not so pointed at the apex; subterminal line almost entirely absent, postmedian line nearer to the margin. Hindwing with a more extensive pink disc. Probably only a form of *melmon* from Cuernavaca (Mexico). — **colenon** Dyar resembles *dandemon*, but the lines are undulate-dentate and more curved, and there is a notched antemedian line, the discal ring marked by dots is filled with brownish; subterminal line undulate. In the ♀ the lines are likewise marked by white scales, the exterior one strongly dentate, marginal area somewhat lighter. Hindwing only at the inner margin red, in the ♀ the disc is darker orange. Also from Cuernavaca. A species hardly separable from the preceding *hebe*.

eogene. **A. eogene** Fldr. (111 A e) belongs yet to the same group; I regard as ♂ two specimens from Mexico of my collection, exhibiting a darker reddish ochreous colour than *hebe*, more smoothly scaled and with more elongate wings; the spots of the transverse lines are much less distinct, the subterminal ones reduced to an anal spot and a subapical spot. Hindwing almost as in *hebe*, the disc deeper orange, the marginal area behind the submarginal line coloured as the forewing. The ♀ is very similar to *dandemon*, larger, more violettish pink like the marginal area of the hindwing, too. Mexico (City, Zacualpan).

io. **A. io** Fabr. (= *corollaria* Perry, *varia* Wkr., *fabricii* Bsdv.) (111 A f) is the well-known North-American species which is often also bred in Europe, rather variable, in the ♂ yellow, in the ♀ dark purple brown or red-brown, with spottedly notched transverse lines which are often, especially in the ♀, bordered with whitish on the inverted sides; discal spot filled with the same colour or brownish, bordered by dots or larger spots. Hindwing dark yellow, at the inner margin and in the subterminal line red. Ocellus large. — ab. **argus** N. & D. is a light yellow male form without any marking, only the large ocellus on the hindwing being visible. Described from Hoboken (N. J.). — **lilith** Stkr. (111 A f) is more obsoletely marked on the forewing, suffused with reddish, the hindwing in the disc not yellow, but blackened. Larva on Mangroves. Florida. — **lutheri** Ckll. (= *fuscus* Luther nec Wkr.) is the common North-Atlantic form of *io*, somewhat larger and generally dusted darker and especially the ♀ more intensely marked yellowish whitish-grey. Rhode Island. — **coloradensis** Ckll., described from Colorado, is similar to the form *fuscus*, but on the forewing more intensely dusted purple or violettish-grey, the ocellus removed very near to the black postmedian line or touching it. Discal spot of forewing usually small. — **neomexicana** B. & Benj. is in the ♀ forewing intensely strewn dark with deep purple grey triangular spots between the veins in the subterminal area. Hindwing as in *coloradensis*, but less intensely suffused with purple. The ♂ resembles a yellow *lilith* with an intensely black-edged discal spot. New Mexico. — **texana** B. & Benj. forms in the male an intermediary between the yellow and red-brown *lilith*-forms, and is similarly marked. The ♀ is dusted with deep purple grey, in the basal portion with orange hairs, also the hindwing darkened deep purple grey excepting the intensely orange ring around the ocellus. Texas. — In Mexico the species becomes much smaller. Forewing of ♂ yellow to ochreous red, the transverse lines much more spotted, towards the inner margin the postmedian and subterminal lines are mostly confluent forming a large blackish-grey spot; ocellus of hindwing smaller, the transverse lines behind it more closely together: **mexicana** subsp. n. (111 A e). Types: ♂♀ in Coll. DRAUDT. The gregariously living larva is green, with star-like hair-tufts and, beginning from the 4th segment, with a white, above red lateral line; it burns severely, lives on many fruit-trees, also on cotton and spins a cocoon between leaves.

erythrops. **A. erythrops** Blanch. has remained unknown to me; very similar to *griseoflava*, but above beautifully orange, the oblique postmedian line of the forewing distinct, especially beneath. Hindwing also beneath with a large red black-edged spot and a transverse band behind it. Chile (Coquimbo). The ♀ is lighter than that of the other species, approaching *acharon* f. *debilis*. Larva set with pointed, severely burning stings, greyish-brown with dingy white subdorsal and lateral lines and orange lines above and beneath the spiracles. On Bromelia, blackberry etc. The young larva lives gregariously, later on singly.

A. gayi Luc. (111 B a) is very similar to the following *griseoflava* and perhaps no different species: above *gayi*. orange with a small red discal streak and a feeble postmedian line almost parallel to the margin, both being very inconspicuous. Hindwing exactly as in *griseoflava*, but the postmedian line is finer black and somewhat more undulate. In the figure by BOISDUVAL the signatures of *gayi* and *lucasii* have been confounded, which mistake was also copied in CONTE's figures. Chile.

A. griseoflava Phil. (111 B a). Forewing greyish-yellow. discal dot red and double, the fine red post-*griseoflava*. median line inwards slightly convex, the transverse lines nearer together than in *erythraea*. Hindwing orange with a red, white-centred and black-ringed ocellus, a greyish-black postmedian line which is bent inward towards the costal margin and is fused with the interior edge of the ocellus, passing over into the broader grey antemedian line which extends towards the inner margin. Beneath the hindwing shows a white dot with a red ring. The ♀ is more greyish-brown with a slight pink shade, the distal area of the hindwing is often intensely blackened, like the basal and marginal areas of the forewing. — **A. acharon** Btlr. is very similar, the ♂ forewing *acharon*. greenish-grey with a very feeble reddish tint, with an orange costal margin and fringe, the blackish lines nearer together than in *erythraea*, the carmine spots at the cell-end similar. The ♀ is less greenish, more reddish, hindwing pink, the two distal thirds blackened, the postmedian line farther from the distal margin than in *erythraea*. — **A. debilis** Btlr. is more yellow than typical ♂♂, more sulphur-coloured, the base of the hindwing and the fringe *debilis*. saffron-coloured, the carmine spots of the forewing very small, the antemedian line less irregular. Chile. — Entirely carmine specimens suffused with blackish without any transverse lines are: **A. izquierdoi** f. n. All these *izquierdoi*. forms were bred by V. IZQUIERDO from one and the same laying of eggs. — There are also specimens in which the basal and marginal areas are suffused with red. — **A. contulma** f. n. (111 B b). Type 1 ♂ from Contulmo in *contulma*. the Berlin Museum. Larva above sepia-brown, beneath light greenish with 2 light yellow dorsal and subdorsal lines, with 2 orange undulate lines above and below the spiracles and 6 yellow stings with black tips on each segment. It lives on *Puya coarctata*, artichokes, and roses.

A. erythrea Phil. (111 B a). Forewing of ♂ above cinnamon-reddish with an olive tint, somewhat undulate *erythrea*. carmine transverse lines, often scaled black on the inverted sides, and with a small red discal spot; basal area and distal margin often suffused with red. Hindwing bright orange, ocellus and lines as in the preceding species, but the lines are broader and deeper black. The ♀ is carmine brown, otherwise marked the same, the postmedian line terminates towards the costal margin almost into the apex, the hindwing is more or less tinted yellow in the disc. Chile. — **A. olivacea** Btlr. (111 B a) differs in the more intense olive tint of the forewing and a broader *olivacea*. orange area of the hindwing and the blackened distal margins of these wings. Larva sepia-brown with 4 white longitudinal lines interrupted in the centre of the segments, and a dark yellow undulate suprastigmatal line and another one below it. Ventrums somewhat lighter and more greenish with 6 large and 2 smaller yellow stings on each segment. It lives on *Fagus pumilio*.

A. lucasii Bsdv. is very similar to *erythrea*, perhaps somewhat smaller, the anterior transverse line *lucasii*. broader red, the posterior one almost straight from the apex to the distal third of the inner margin, distinctly black, and between the veins slightly undulate inwards; behind it the whole marginal area is purple red. Hindwing as in the preceding species, but in the marginal area broadly suffused with purple red. Chile. Probably also only a form of *erythrea*.

A. microphthalma Izquierdo (111 B b) is much lighter yellow with a loam-coloured shade, the apex of *microphthalma*. the forewing very pointed, the anterior transverse line is absent, the posterior line is grey beginning at the costal margin 2 mm before the apex, with 2 grey discal dots. Hindwing in the disc somewhat more reddish yellow, with a very small black white-centred ocellus without any red, the feeble lines similarly shaped as in the preceding species, reddish-grey. ♀ more ochreous, strewn with a somewhat darker colour, the lines more reddish-brown. Chile.

Subordinate group: *Hyperchiria* Hbn. (Forewing angular below the apex; eyes red.)

A. incisa Wkr. (= *orodes* Bsdv.) (111 B b). Forewing loam-coloured to reddish-brown, with 2 fine *incisa*. brown transverse lines, a feebler median shadow between them, before which there is a fine discal streak; marginal area more or less smoked like the interior border of the subterminal line. Hindwing yellow or reddish-yellow with a large red, white-centred and black-edged ocellus and 2 broad blackish bands behind it, with a very feeble antemedian line. Abdomen orange, with black bands. Brazil, common.

A. orodina Schs. (111 B c) is extraordinarily similar to *incisa*, somewhat smaller, with an almost *orodina*. straight distal margin with a hardly noticeable angle; forewing lighter greenish-yellow, with very fine transverse lines. Hindwing of a purer lemon-colour. The ♀ is much browner. From Rio Grande do Sul to Paraguay. The thick cylindrical larva is light bluish-green, with very dense spiny hair, with dark pink ring-indentations. It lives on *Sapintacia* spec.

A. nausica Cr. (111 B c). Forewing brown, behind the postmedian line olive greenish-yellow with 2 very *nausica*. oblique blackish transverse lines, a less distinct median and subterminal shadow and a black discal spot situate in a greenish halo. Hindwing bluish-grey with an orange, white-centred and black-ringed ocellus, in the costal-marginal third brownish, with 2 broad black undulate transverse bands the interior one of which mostly unites with an antemedian one at the inner margin. Abdomen orange, with black bands. The ♀ is much browner.

- azteca*. From Guiana, Peru and Bolivia; also from Trinidad. — **azteca** *f. n.* (111 B c) has somewhat broader wings, the distal portion being of a purer sulphur-colour, the discal spot the same, almost without a black centre; the orange ocellus of the hindwing without a white centre, the black binds much lighter and narrower; the abdominal belts so, too. In numbers from Mexico: type in the Coll. DRAUDT.
- acutus*. **A. acutus** *Conte* (= *flavus Conte*) (111 B c) is similar to *azteca*, but at once discernible by the carmine ocellus; forewing more intensely dusted black, the two transverse lines black, less oblique and quite straight, the discal spot and the subcostally angled median shadow greenish-yellow like the marginal area in which there are single black vein-dots. Abdomen yellow, with black rings. Peru. *flavus* is surely only the ♂ of *acutus*-♀: there are 2 fresh ♂♂ from Vilcanota before me, from the Berlin Museum, which also exhibit a black-banded abdomen.
- aniris*. **A. aniris** *Jord.* is quite similar to *nausica* from which it is easily separated by the entirely black ocellus of the hindwing lacking a white central dot; lines of forewing less oblique, almost parallel to the distal margin. Costal margin of hindwing not lobate as in *nausica*, but uniformly convex. British Guiana.
- plicata*. **A. plicata** *Herr.-Sch.* (= *laciniata Bsdv.*) (111 B d) has a more intensely dentate distal margin of the forewing, and the dent below the apex is strongly bent downward; forewing marked as in *nausica*, but the colour is a dull brown without the yellowish marginal brightening. Bands of hindwing much more dentate. Brazil.
- cypria*. **A. cypria** *Gmel.* (= *io Cr.*, *stollii Bsdv.*) (111 B d). Forewing of ♂ reddish-brown to olive-brown with fine blackish transverse lines, the anterior one somewhat irregularly notched, the posterior one much feebler, beginning before the apex, between them a somewhat broader median shadow and a large oval whitish discal spot with a darker median streak, with some fine submedian black vein-dots; subterminal line below the apex with a small black spot, in the lower half twice projecting arcuately. Hindwing light brownish or reddish-grey with a red, white-centred and black-edged ocellus and 2 blackish transverse bands behind it. The ♀ is purple brown, dusted with violettish-white, especially in the marginal area, with a double postmedian line. Amazons, Rio de Janeiro. — **vala** *Ky.* (= *crameri Bsdv.*) based upon the very bad figure of the ♂ by CRAMER, likewise from Surinam, I do not consider to be a different species, only distinguished by a somewhat lighter, more reddish yellowish-brown ground-colour, though the colour is rather variable. — **pericinctus** *Conte*, in my opinion, is neither to be separated and refers to an otherwise typical damaged female specimen — not a ♂ as CONTE states in the text —, which shows some blackish shading also before the ocellus of the hindwing, forming together with the black postmedian line a circle around the ocellus. French Guiana.
- caudatula*. **A. caudatula** *Fldr.* (111 B d) has narrower wings with a more produced apex and a roundish tail-like extended angle on the hindwing. Forewing olive brownish, the markings as in *cypria*, but whitish, on the veins whitish, dark-centred dots. Hindwing hardly lighter brown, the two transverse bands behind the ocellus only little darker, the marginal area slightly dusted white. Abdomen ochreous, curled black. An evidently very rare species, reported from Central America, in the Berlin Museum a ♀ from Oxapampa (South-Eastern Peru).
- bulaea*. **A. bulaea** *M. & W.* (111 B d) is a very small species belonging to the same group; forewing very similarly marked as in the preceding species, but the apex of the forewing is falcately extended, not angular below it: olive brown, dusted with red-brown and lilac white, postmedian line double, discal spot very large. Hindwing coppery reddish-brown with a black, feebly whitish-centred ocellus, at the margin shaded with olive green. Beneath marked as the preceding species, the marginal areas of both wings dusted with brownish olive green. Southern Brazil (Novo Friburgo). Subordinate group.: *Gamelia* *Hbn.* (Forewing very broad with a long and pointedly extended apex in the ♀; eyes red.)
- abas*. **A. abas** *Cr.* (111 B a), 130 b. The ♂ is purple brown on the forewing, in the basal area darker, bordered by the dentate indistinctly double black antemedian line which is filled with single greenish-yellow hairs, the very small discal spot surrounded by black; the postmedian line comes from the apex and is likewise double, at the margin light red-brown, the ocellus red, centred white and encircled with black, behind it 2 grey lines, from the ocellus to the inner margin almost straight, from the ocellus to the costal margin recurved far towards the base, the interior line fine, the exterior one broader, widened analwards. The ♀ is more blackish-brown, in some places dusted with lilac grey, the apex of the forewing much longer, the discal spot larger, filled with brownish, encircled with light grey, the postmedian line inside bordered with a darker colour. Guiana, Amazons, Peru.
- abasia*. **A. abasia** *Cr.* (111 B e) is similar, somewhat smaller on an average, lighter brown, the antemedian line entirely absent, the basal area hardly darkened, the discal spot punctiform or a fine black circle, the postmedian line represented by 2 more intensely outlined black parallel lines. Hindwing lighter, more brownish, the red iris of the ocellus larger, the black ring relatively narrow, the grey lines more curved. Guiana, Amazons, to the north as far as Panama. Larva violettish-grey with a yellow lateral stripe and black burning stings provided with yellow branches. According to CRAMER, it lives on Guayavae.

A. pyrrhomelas Wkr. (♀ = *anableps* Fldr.) (111 B e, 130 e). The ♂ is somewhat larger than *abas*, otherwise very similarly marked, but of a more purple blackish ground-colour, the antemedian line very indistinct, the inner portion of the postmedian line thicker than the outer part, towards the costal margin inside of it a lighter brownish-grey triangle, coloured like the marginal area. Hindwing similar as in *abas*, but greyer, the 2 lines behind the ocellus stronger, the inner margin blacker haired. The ♀ is likewise similar to *abas*-♀, the postmedian double line more distinct, inwards not so strongly shaded, with a large oval lighter brownish spot at the costal margin. Colombia, Bolivia, Brazil.

A. banghaasi sp. n. (111 B f) is very similar, darker slate-coloured black, strewn with fine silvery blue scales particularly in the marginal area and in the distal half of the median area; only the basal area is dark carmine-brown, the shape of the lines as in *pyrrhomelas*, but the postmedian line terminates nearer at the apex; discal spot conspicuously earmine, above and beneath bordered by one thick black dot each. Hindwing almost unicoloured slate-black, ocellus larger with a narrower black ring. Shape of hindwing longer stretched, with an entirely rounded anterior angle. Abdomen above black, beneath and at the anus bright rusty red. According to a ♂ from St. Louis, type in the Coll. BANG-HAAS.

A. rubriluna Wkr. I do not know; according to the insufficient description based upon a ♀, it is nearest *rubriluna* to *abasia*-♀. Blackish grey, forewing very falcate, tinted with reddish-brown excepting the basal portion, the black postmedian line hardly bent, from the distal third of the inner margin to the apex, double, filled with reddish-yellow; the small blackish discal spot is mixed with red and encircled by reddish-yellow. Ocellus of hindwing large, round, carmine, centred white and broadly surrounded by black, behind it a blackish line, then a blackish curved band. Length of forewing: 30 lines. Amazons.

A. barii Bsdv. (111 B e) is somewhat smaller than *pyrrhomelas* and is intermediary between the latter *barii* and *abas*, with a rounded anterior angle, ocellus smaller, darker, the lines nearer together. Cayenne. Surinam.

A. pandarus Bsdv. According to the description and the figure supplied by CONTE this species must look almost like *abas* or *barii*, though it has 2 black central dots in the pinkish-white pupil of the ocellus on the hindwing. Brazil.

A. theseus Bsdv. is also similar, but the pupil of the ocellus on the hindwing shows but one black central dot; the two lines have the same course as in *abas*, but they are a little more remote from the ocellus than in *pandarus*, where the inner line touches the ocellus. Patria unknown. They presumably are both only variable forms of one species.

A. arguta Bsdv. (= *anableps* Conte nee Fldr.) (130 b) is allied to the preceding species, but of a bright red-brown with a slight purple tint, the postmedian double line very distinct, filled up with whitish, the round discal spot and an oval spot before the postmedian line at the costal margin yellowish greyish-white, the antemedian line beginning at the costal margin with a white spot. Hindwing lighter, the pinkish-white pupil of the very large ocellus pupilled black. The ♂ is lighter and more yellowish than the ♀. Colombia, Ecuador; the statement Mexico is wrong.

A. irmina Cr. (♀ = *episcopus* Bsdv.) (111 B f, 130 d) is smaller than *abas* and very similarly marked, but much lighter yellowish red-brown, the basal area darker, the antemedian line as in *abas*, but more distinctly double, filled with greenish-yellow like the round discal spot which is finely surrounded with blackish; the subterminal line is spotted, the extreme apex blackened. Hindwing light pinkish-brown, the transverse lines behind the ocellus very feeble, not recurved basad at the anterior angle, by what the species is always discernible especially in the female. The ♀ is more greyish brown or purple brown, the transverse lines on the inverted sides broadly bordered with red-brown, so that only a narrow median band remains, strewn with lilac grey; on the hindwing the exterior band is very broad analwards. Panama, Guiana, Colombia, Ecuador, Amazons.

A. catharina sp. n. (111 B f). In Southern Brazil *irmina* is represented by a similar species of a stronger structure, resembling also *abas* and, on the other hand, *arguta*. Forewing bright red-brown, basal area darker, distally defined by the antemedian line which is scaled blackish and yellowish-green and strongly notched as in *irmina*; discal spot small, blackish, surrounded by greenish yellow; postmedian line as in *abas*, inside scaled somewhat whitish, at the costal margin before it a yellowish spot as in *arguta*. Hindwing on the light red-brown ground grey-haired; ocellus large, of a bright earmine with a small pinkish-white centre, broadly edged with black; behind it 2 greyish-black lines which bend round farther basad at the costal margin and are more distinct than in *irmina*, the exterior one somewhat broader; margin light reddish-brown. Type: 1 ♂ from Sa. Catharina in the Berlin Museum.

A. remissa Weym. (130 b) is easily distinguished from the preceding species by the course of the postmedian line of the forewing, beginning at the costal margin 5—8 mm before the apex and terminating into the inner margin parallel to the distal margin. Ground-colour pinkish-brown, basal area and the subterminal area strongly darkened. Hindwing light pinkish brown, dusted with black, the ocellus small, dull red, centred

white, the two lines behind it removed far apart, the area between them of a purer pinkish brown. Brazil (Espiritu Santo); a couple from Passa Quatro, Sul de Minas, is much smaller, the ♀ was figured.

seitzi. **A. seitzi** *sp. n.* (111 B f) is allied to *remissa*, but larger; costal and distal margins almost straight, apex very pointed, produced; forewing light brownish-grey; antemedian line darker, inside bordered with light, straight to the inner margin; discal spot oval encircled with a somewhat darker colour; postmedian line from 5 mm before the apex to the distal third of the inner margin, very feebly incurved, olive-brown, behind it a slight doubling separated by a somewhat lighter interspace and terminating outside directly into the subterminal band. Hindwing basally with pink hairs, ocellus red, with a tiny white centre and a black ring; postmedian line almost straight, slightly bent only at the costal and inner margins, blackish, outside broadly scaled yellowish-red, behind it, separated by a narrow space, strewn with grey scales. Beneath the disc of the forewing shows a red shade, the postmedian lines are in both wings straight, brown, scaled red. Type: 1 ♀ from Peru in the Senckenberg Museum, Frankfurt-on-the-Main.

musta. **A. musta** *Schs.* I know only from the description according to which it must be very closely allied to *catharina*, though much larger. The ♂ is dark red-brown in the basal third, bordered by the double blackish brown antemedian shadow which is filled with yellowish, behind it lilac brown, the postmedian line double, filled with reddish-yellow; discal spot ochreous, parted by a blackish central streak; before the posterior line with a reddish-brown costal-marginal spot. Hindwing reddish yellowish-grey, darkened at the inner margin, ocellus large, red, white-centred, with a broad black ring, and distally produced to the distal margin through the blackish-grey postmedian line; subterminal shadow widened analwards, but it remains here far above the anal angle; marginal area lilac brown. Expanse of wings: 68 mm. According to a ♂ from Costa Rica (Juan Vinas).

pygmaea. **A. pygmaea** *Schs.* (111 B e) is a very small species; forewing red-brown, without the antemedian line, the postmedian line fine, yellowish-white, on both sides very feebly and finely bordered by a darker colour, the tiny whitish discal spot inside bordered with black. Hindwing pinkish-brown, with hardly any markings except the red, black-ringed ocellus with a black centre in a lighter halo. S. Paulo (Brazil).

auletes. **A. auletes** *H.-Schäff.* (111 B f, 130 e) is unmistakable. Forewing rusty yellowish-brown, especially in the median area with black white-ringed vein-dots; transverse lines very fine, double, filled with a lighter colour, the very large yellowish greyish-white discal spot before the distal border with a fine black interior ring and a black central streak with a distally extending transverse streak; between 6 and 7 below the apex a blackish spot, behind it dusted whitish. Hindwing in the disc very light lilac grey, base, costal margin and inner margin with light cinnamon-reddish hair; ocellus carmine with a white centre and a black ring, behind it 2 grey transverse lines, the exterior one duller and broader, particularly analwards. Guiana and Venezuela.

8. Genus: **Ancistrota** *Hbn.*

Structurally closely allied to the *irmina*-group of the subgenus *Gamelia*, separated by the slightly drooping last palpal joint; on the forewing the uppermost subcostal branch arises much more remote from the upper cell-end; on the hindwing 6 and 7 arise on a stalk, in *Gamelia* 7 comes distantly separated from the upper cell-edge. Only 2 species: type: *A. plagia* *Hbn.*

plagia. **A. plagia** *Hbn.* (112 a). Above bright yellow, antemedian line of the same shape as in *irmina*, brownish, towards the base bordered with white, the posterior transverse line from the apex to the third quarter of the inner margin, likewise inwardly bordered with white; at the cell-end a variably large black ring filled with white, often centred black; instead of the subterminal line more or less distinct small purple brownish spots, the lowest removed towards the base. Hindwing in the basal third with brownish hair, in the disc a small, dull, brownish spot, behind it a rather straight postmedian line, before the margin a few small brownish subterminal spots. The larger ♀ is red-brown or pinkish-brown, in the median area with a slight lilac shade. Brazil. — *ferruginea*, **ferruginea** *f. n.* (112 a), from Petropolis (type in the Berlin Museum) is also in the male entirely red-brown above.

stramentalis. **A. stramentalis** *sp. n.* (112 a) is somewhat larger on an average, the forewing more straw-coloured, the postmedian line extends from the apex obliquely to the centre of the inner margin, it is not bordered with white, but distally feebly shaded with red-brown; at the cell-end only a feebly darker streak. Hindwing as far as the subterminal line dusted with red-brown, the subterminal line darker red-brown, notched. Abdomen yellow, brownish above excepting the last 2 rings. Peru (Callanga); Bolivia (Songo; Corvico). Type: ♂ from Peru in the Berlin Museum.

9. Genus: **Cinnomata** *Btlr.*

More robustly built than the preceding genus with a long and densely haired thorax. Last palpal joint straightly porrect or slightly drooping. Wings, especially of the ♀, more elongate, the costal margin of the

hindwing quite straight. ♂ antennae bipectinate, ♀ filiform. Veins of forewing as in *Gamelia*, but in both wings the cross-vein extends very obliquely in a straight line from above inside to below outside; on the hindwing 6 and 7 comes from the upper cell-angle.

C. bistrigata *Btlr.* (112 a). Pale straw-coloured, in the ♂ more intensely, in the ♀ less strewn with olive *bistrigata*. brown, from the apex to the base of the inner margin a blackish longitudinal line above bordered with yellowish-white, slightly flawed at the lower cell-angle, and a double straight subterminal line filled with white. Hindwing of ♀ similarly coloured, of ♂ more reddish ochreous with a black central dot and a blackish postmedian line flawed above 6. Chile.

10. Genus: **Prohylesia** *n. g.*

Connects *Ancistrota* with *Hylesia*; in general of a structure similar to that of *Ancistrota*, the last palpal joint not drooping, but very feebly turned obliquely upward, longer than in *Hylesia*, antennae shorter than in *Hylesia*. in the ♂ bipectinate, in the ♀ very short and thin filiform or set with short bristly hairs. Prothorax with a flatly compressed, comb-like erected tuft; abdomen shorter than hindwing, without the long hair of *Hylesia*. Veins of forewing exactly as in *Ancistrota*, hindwing with an almost hook-like projecting costal-marginal angle, especially developed in the ♀ (similarly as in *Automeris flexuosa-mendosa*). Veins likewise as in *Ancistrota*, but 6 and 7 not stalked, but together with 5 all three arise at equal distances, only in *friburgensis*-♀ 6 and 7 arise from the same place of the upper cell-angle.

Type: *P. friburgensis* *Schs.*

P. zikani *sp. n.* (112 b) ♂ on the very light brownish ground shaded and strewn with a darker brown, *zikani*. with 2 fine dark transverse lines on the averted sides bordered with whitish, the anterior one vertical on the inner margin, the posterior one begins 5—6 mm before the apex and extends convergently to the former to the inner margin, where it is 2—4 mm distant from it; at the cell-end there is a large reniform light macula before which the cell is darkened brown; behind the postmedian line darker spotlike dusting; the subterminal line is irregular, with spotlike notches, blackish-brown. Hindwing dusted with red-brown, with 2 curved blackish-brown postmedian transverse lines, between and behind which the ground of the wing is lighter, the posterior line from the darkened apex; at the cell-end a light spot. The ♀ is uniformly suffused with chocolate-brown, with a pinkish lilac tint, the markings as in the ♂. Type: ♂ from Sa. Catharina, ♀ from Passa Quatro (Minas), ZIKAN leg., both in the Coll. HOPP. Co-type 1 ♂ from Sa. Cruz in the Senckenberg Museum.

P. rosalia *sp. n.* (112 a) is somewhat similar, of a light pinkish-brown ground-colour, the two transverse *rosalia*. lines more distinctly dark brown, slightly undulate, not bordered with a lighter colour, of the discal spot only 2 black dots at the upper and lower ends are visible, of the subterminal line only 2 black dots above the anal angle; before the cellular dots and behind the postmedian lines at the costal and inner margins some olive brown shading. Hindwing red-brown as in *zikani*, only the interior postmedian line more distinct, the exterior one rather indistinct. Thorax light yellowish-grey, the edge of the prothoracal comb darker brown. 1 ♂ from Passa Quatro, Minas, Brazil. Type in the Coll. HOPP-Charlottenburg; a ♂ more intensely dusted olive brown, from Leopoldina, in the Berlin Museum.

P. friburgensis *Schs.* (112 b) was described as a *Micrattacus*. Head and thorax yellowish-grey, abdomen *friburgensis*. light reddish-brown. Forewing yellow reddish-grey, strewn with black hair-scales, costal-marginal area above the median vein and 4 dusted with light reddish-brown; transverse lines straight, whitish ochreous, distally shaded dark, the basal oblique line from the base of the costal margin, the antemedian line feebly excurved, the postmedian line slightly incurved, at the cross-vein a blackish-brown streak bordered with ochreous white; the light subterminal line extends sharply notched from 4 to the anal angle; costal margin grey. Hindwing light reddish-brown with a fine blackish-brown cross-vein shadow; behind the fine black distal line an irregular blackish-brown shadow; ends of fringes white. Forewing beneath yellow, at the costal margin red-brown. The ♀ is more intensely darkened olive grey, the transverse lines with a broader light border, the discal spot below widened in the shape of a hammer and filled here with deep black. Novo Friburgo, Rio de Janeiro.

11. Genus: **Hylesia** *Hbn.*

An uncommonly large and uniform genus, probably the most difficult item in the whole lepidopteral world, since it appears to have been impossible hitherto to separate the species by differences in the sexual armatures. Structurally it scarcely differs from *Automeris*. Chiefly small grey species, mostly thinly scaled, apex of forewing often more or less feebly falcate. On the hindwing 5, 6 and 7 arise more distantly separated than in *Automeris*, the abdomen shows longer and coarser hair. Mr. HOPP-Charlottenburg, who has minutely investigated into the *Hylesia*, writes to me about them: It is rather very difficult to decide which is a species and which a variety, since there are no morphological differences whatever; some of the larvae, however, vary

to a great extent. Most of the larvae live gregariously in large nests from which they wander at night to the feeding place in processions, returning in the morning by the same way. There are also, however, without doubt *Hylesia* that lead a solitary life.

In elaborating this genus I was most kindly aided by Dr. SCHAUSS-Washington, who was able to identify all the species before him. The National Museum of Washington contains the types of nearly all the species so that in this way they could be most reliably identified. Most of the new species were denominated by SCHAUSS.

Type: *canitia* Stoll.

Sect. 1. Hindwing at least of ♂ with an ocellus (*Micrattacus*).

nanus. **H. nanus** Wkr. (= dissimilis *H.-Schäff.*) (112 b). Forewing with a very falcately produced apex. Ground-colour of ♂ copper reddish-brown, at the apex darkened, with fine yellowish transverse lines which are finely bordered with dark on the inverted sides, the anterior line undulate, interrupted towards the base below the cell, the posterior line almost straight, from about 5 mm before the apex, the subterminal area behind it somewhat blackish; at the cell-end a greenish-grey oval macula finely encircled and centred with dark. Hindwing in the disc darkened, with a yolk-coloured small ocellus with a fine darker, sometimes also fine orange red ring and tiny centre; the marginal area behind the almost straight postmedian line redder than the forewing. Abdomen rusty reddish, thorax in the middle and at the end deep dark brown. The ♀ is monotonously brownish or blackish grey, the markings arranged as in the ♂, but slightly darker. Abdomen with ochreous hair. Colombia; Brazil; Bolivia.

scortina. **H. scortina** sp. n. (112 b) is of the same shape, though larger, the ground light tan-coloured brownish, at the apex dark violettish-grey, the transverse lines blackish-brown, fine, at the inner margin much nearer together than in *nanus*, the macula at the cell-end much larger, narrowly oval or feebly reniform, coloured like the ground, very rarely with a feeble greenish tint. Hindwing dark violettish-grey, in the marginal area with a rusty reddish hue, ocellus and lines as in *nanus*. Abdomen reddish ochreous. Brazil; Paraguay. Type in the Berlin Museum in Coll. STGR. Numerous ♂♂, but no ♀ that might have been identified except perhaps 1 ♀ which resembles *nanus*-♀ on the wings excepting the much longer discal macula, whilst the abdomen is like that of *corevia*.

corevia. **H. corevia** Schs. (112 c) has broader wings, a slightly falcate apex of the forewing, a most variable ground-colour, tan-coloured brownish, ochreous, red-brown or almost entirely violettish-grey, in the costal portion often greenish-yellow, marked very much like *nanus*, the anterior transverse line still more undulate, the discal macula of a very different size, mostly filled with yellowish-green or greyish-green. Hindwing as in *nanus*, but the ocellus more broadly surrounded with rusty red; mesothorax and metathorax varying between red-brown and black. Abdomen beneath red, with black bands. ♀ very large, purple blackish, discal macula and posterior transverse line broad, bordered and filled with black. Abdomen above black, laterally and beneath rusty yellow. A most variable species from Brazil.

metapyrrha. **H. metapyrrha** Wkr. (112 c) I should have considered to be the same species as *corevia*, judging from WALKER's description, but TAMS writes to me with reference to it: "Nobody can give any information about it, HAMPSON has not discovered the type, and neither myself nor Lord ROTHSCILD to whom I spoke about it can gather anything reliable from the description, I do not believe that it is the same as *corevia*." ♂ light rusty brown, thorax with a posteriorly widened black median stripe; abdomen beneath bright red, with black bands. Forewing along the costal margin indistinctly tinted greenish, the roundish discal spot brownish-white, bordered with black and centred black; behind $\frac{3}{4}$ of the length an oblique band, distally undulate, inside bordered with light, towards the apex obsolete, the apex itself blackened. Hindwing towards the inner margin purple blackish, at the distal margin reddish-yellow with a slightly undulate blackish band; discal spot almost round, yellow, indistinctly encircled with brown. Hindwing beneath purple violet, $\frac{1}{3}$ of the distal portion reddish-yellow with an oblique black band which borders on this colouring and separates it from the yellow, black-centred discal spot. Rio de Janeiro. This description exactly fits the figure of our ♂ from Passa Quatro, which, however, can by no means be specifically separated from *corevia*-♂, as all the transitions are present.

lineata. **H. lineata** Drc. (= *ondulatus* Conte) (112 c) is distinguished from the similar species by the hindwing projecting angularly on vein 3; forewing light brownish, basally, in the costal half of the median area, subterminally and in the upper half of the distal margin darkened blackish, with 2 light transverse lines, on the distal sides bordered with dark, often olive greenish, at the cell-end with a dark, white-centred ring; subterminal line in the upper half forming a bow which is concave towards the margin. Hindwing with a rather large carmine ocellus sometimes centred light and with a broad black ring, and 2 olive blackish lines behind it. The ♀ is reddish-grey, the markings slightly darker, broader than in the ♂, the ocellus on the hindwing marked by a feeble ring. Abdomen ochreous, above black. Mexico to Costa Rica.

subaurea. **H. subaurea** Schs. (= *coadjutor* Dyar) (112 c) is very similar, somewhat larger, more monotonously coloured, without the dark shading, the transverse lines bordered with a somewhat lighter, though not contrasting colour, more olive green. Hindwing less angular, ocellus not round, but elongate. Mexico (Orizaba).

H. funebris *Conte* I know only from the description and figure in CONTE, Essai etc., it seems to be very *funebris*. similar to *subaurea*, but much more distinctly and contrastingly marked and of a more blackish-grey ground-colour, with ochreous lines inwardly bordered with whitish, the subterminal line distinctly whitish. Hindwing more brownish. Abdomen ochreous, with black rings. Honduras.

H. omeva *Dyar* (112 e, d) is still larger and has much broader wings, the hindwing without any angle, *omeva*. variably coloured, mostly lighter with a somewhat pinkish tint, otherwise very similarly marked; the black ring of the ocellus thinner, especially on the side of the inner margin. The ♀ is brownish pink, thinly scaled, feebly marked, ocellus of hindwing marked by a feeble blackish ring filled with pink. Mexico (Zacualpan).

H. iola *Dyar* (112 d) is likewise very similar, lighter, brownish-pink, discernible by the ocellus on the *iola*. hindwing representing a small crimson ring. Abdomen above blacker than in the allied species. The ♀ is exactly like *omeva*-♀, but lighter, the ring of the hindwing is red, not blackish. Mexico.

Seet. II. Hindwing without an ocellus (*Hylesia*).

a) Hindwing of ♂ strongly angled below the centre.

H. melanostigma *H.-Schäff.* (112 d). A well characterized species, with a falcate apex of the forewing, *melano-*
light brown, with 3 darker transverse lines, the two first lines oblique, distinct, distantly separated, the *stigma*. subterminal line parallel to the margin, more obsolete; at the cell-end with a very conspicuous oblique black spot. Hindwing with 2 postmedian lines very near together, abdomen rusty yellow, metathorax dark brown. The ♀ the same, but the apex of the forewing not falcate. Guiana. — **propex** *f. n.* (112 d), from Western *propex*. Colombia, is much darker lilac brown, the discal spot much shorter and narrower, encircled with light, the transverse lines towards the margin bordered with a lighter brownish pink, the subterminal line inside broadly shaded; hindwing at the inner margin black-haired. Abdomen blackish-brown, with yellowish ochreous and whitish hair. Type in the Coll. NIEPELT.

H. gyrex *Dyar* (112 d), as *melanostigma*, but with a very feeble discal streak, the two median transverse *gyrex*. lines nearer together, therefore the subterminal area much broader. On the hindwing only a curved nebulous postmedian line is visible and a very feeble subterminal shadow between this line and the margin. Guiana, Colombia.

H. vespe *Dogn.* (112 e) is likewise similar to the two preceding species, but the transverse lines are *vespe*. less oblique, the antemedian line vertical on the inner margin, the postmedian line here 3 mm farther outside, extending to the costal margin parallel to the distal margin; marginal and basal areas somewhat lighter lilac brownish, discal spot black. The ♀ is similarly coloured and marked, but it has no falcate apex of the forewing, a lilac whitish brightening at the apex. Upper Amazons (S. Paulo de Olivença). Ecuador (Maeas).

H. aeneides *Drc.* (112 e) differs considerably from all the species known in the more slender structure, *aeneides*. the very broad shape of the wings, and a somewhat undulate margin. Forewing brown, in the median area and subapically darker, subterminally and in the inner-marginal half of the median area intensely strewn with bluish-white; transverse lines similar as in *corevia*, discal macula as in *nanus*. Hindwing pinkish-brown, with 2 inwardly faded blackish transverse lines, the distal line between the veins 2 and 4 with 2 rounded projections towards the tail, and a dark central dot. Abdomen ochreous red. The ♀ is more monotonously greyish-brown, thinly scaled, apex of forewing as in *praeda*-♀ extended into a fine point. Panama; Amazons, Colombia.

b) Hindwing not angular.

H. praeda *Dogn.* Forewing brownish or brownish-grey, in some places tinted with lilac, with a large *praeda*. discal spot and broad, very oblique blackish-brown transverse lines, the posterior line flatly undulate, with a finer parallel line behind it, bending round shortly before the costal margin in an acute angle towards the base, here as far as the apex a narrow dark brown trapezoid spot above it; subterminal line shaded, below the centre projecting towards the margin. Hindwing lighter, greyer, with 2 nebulous postmedian lines and a feeble discal spot. Abdomen black with cinnamon-reddish anal hair. The much larger ♀ is more blackish violet. Ecuador; Colombia; Guiana; Amazons.

H. rufex *sp. n.* (112 e) is a very peculiar insect, its scheme of markings somewhat similar to that of *rufex*. *praeda*. Forewing in the basal two thirds light violettish-brown, behind the postmedian line rusty yellowish-brown; basal area darker; antemedian line blackish-brown, in the cell and submedianly projecting; at the cell-end a large olive yellowish macula finely surrounded by dark and parted by a dark cross-bar; postmedian line similar as in *praeda*, but beginning from the acute-angular bend it extends in a large flat, distally concave bow to $\frac{2}{3}$ of the inner margin, double, the interior stronger line bluish-black, the exterior one brown, more shaded; subterminal line shadow-like as in *praeda*. Hindwing ochreous, in the basal $\frac{4}{5}$ dusted with cinnamon-brown. Thorax violettish-brown, abdomen ochreous. Beneath with 2 straight postmedian transverse lines, forewing before it red-brown, behind it ochreous, hindwing rusty red, before the line dusted light lilac. The ♀ is more dark brown, in the basal $\frac{2}{3}$ of the hindwing dusted with lilac. Brazil (Minas Geraes; Sa. Catharina). Types in the Berlin Museum.

H. index *Dyar* (112 f). Forewing sooty yellowish-brown, densely dusted with light lilac, with broad *index*. shadow-like olive brown transverse lines similar as in *praeda*, but less oblique, vanishing towards the costal

margin, between them with a large discal shadow-like spot; subterminal line as in *praeda*. Hindwing greyer with 2 darker postmedian nebulous lines and discal spot. Abdomen ochreous brown. Peru, Amazons (before me from Itaituba e Coll. STGR.).

annulata. **H. annulata** Schs. Thorax and abdomen above black, beneath golden ochreous. Forewing brownish-grey with blackish-brown transverse lines, the interior one inwards, particularly at the costal margin, bordered with light reddish-brown, interrupted below the cell, in the cell outside with a light brown spot, behind it with a large blackish-brown discal ring filled with light brown; exterior transverse line fine, dark brown, apex blackened, subterminal line an irregular brownish shadow, the margin behind it darker and strewn with olive brown. Hindwing olive grey, cell and inner margin blackish-brown, with a dark postmedian line, subterminal shadow and discal ring. Expanse of wings: 56 mm. Costa Rica.

ochrifex. **H. ochrifex** Dyar is allied to *annulata*, smaller, at once discernible by the ochreous abdomen with its brownish bands. Apex of forewing hardly falcate as in *annulata*; discal ring smaller, finer and less shaded, the dark area at the base less black, more intensely light-spotted, the distal line less curved. Expanse of wings: 44—48 mm. Carabaya (Peru).

rufipes. **H. rufipes** Schs. Thorax blackish-brown, with lilae hair, abdomen above black, laterally, beneath and at the end red, with rosy-red feet. Wings lilae pink, with fine olive brown veins and similar transverse lines, the interior one almost straight, inwardly shaded with blackish brown, the posterior line a dark shadow with a line which is distantly separated from the posterior line, but confluent with it on vein 4; at the cross-vein a dark brown more or less ring-shaped shadow; subterminal shadow of the usual shape with distal projections between 2 and 4. Hindwing at the inner margin brownish with a feeble discal spot, a dark postmedian line and subterminal shadow. Expanse of wings: 41 mm. Costa Rica.

scalex. **H. scalex** n. sp. (112 f). Allied to *ochrifex*, lilae brown, basally and in the median area darker purple brown with lighter spots, the base of the inner margin as well as the basal area of the hindwing with ochreous hair; antemedian line almost covered by the dark basal area, the discal ring, too; posterior transverse line feebly curved S-like, double, the interior portion distinctly dark brown, the exterior part somewhat lighter, distally faded, between these parts fine dark veins, looking like the rungs of a ladder; marginal area very light, subterminal line sharply and pointedly notched on 5, 6 and 7. Hindwing as in *index*, the interior postmedian line more angular. Abdomen ochreous, with brown bands. The ♀ is monotonously grey with a slight lilae tint. ♂ type from the Rio Songo (Berlin Museum), ♂ co-type from Villavieencio (Colombia). Coll. HOPP-Charlottenburg, ♀ type from Pto. Alegre, Rio Paehitea, in the Berlin Museum.

gigantex. **H. gigantex** sp. n. (114 f). Very large, apex of the wing produced, distal margin oblique. Sooty brownish, antemedian line rather indistinct, of the same shape as in *scalex*, far produced in the cell, nearing the discal spot and almost parallel to it, receding on the median vein as far as the origin of 2, and once more obtusely distally angled on the submedian fold; discal spot large, hazy black; the dark, distally light-edged postmedian line parallel to the margin, forming fine distal toothlets on the veins; subterminal band defined by the lighter marginal area, forming pointed dents on 6 and 7, and above it terminating with the most pointed and darkest dent into the apex, projecting rounded between 2 and 4. Hindwing with a very feeble discal streak, postmedian and subterminal lines, the latter line very near to the margin. Abdomen with rusty brown hair. Type 1 ♀ from Bella Vista (W. Colombia) in the Coll. W. NIEPELT.

polyploca. **H. polyploca** sp. n. (112 f) has narrower wings than *gigantex*; light grey, finely dusted with white, at the costal margin broad white, with brownish-grey transverse lines and a distinct discal ring; anterior transverse line below the costal margin at first inwardly angled, on the subcostal vein pointedly outwardly angled, below the cell inwardly broken off, then obliquely outward to the centre of the inner margin, inwardly bordered with a lighter colour, the exterior line somewhat distally produced on the veins, with a feeble darker shadowy line before it, which bends down subcostally as a broad distinct nebulous stripe and extends vertically to the costal margin, behind it with the darker subterminal shadow of the usual shape; the darkened apex is parted by a white oblique patch. Hindwing very light pinkish-grey, at the margin brownish-grey, sharply defined by the subterminal shadow, before it with a very feeble postmedian shadow. Thorax grey intermixed with long white hairs, base of abdomen, abdomen above black, laterally narrowly rusty yellow, ventrum light greyish-brown. Type: 1 ♂ from Brazil, exact habitat not mentioned, in the Berlin Museum; 1 ♂ co-type with broader wings, more shaded, from Passa Quatro (Southern Brazil) in the Coll. HOPP-Charlottenburg.

e) *acuta*-group with a falcate apex of the forewing and a dark brown oblique basal band at the inner margin.

acuta. **H. acuta** Drc. (112 f) is monotonously lighter or darker pinkish-brown, with hardly any markings excepting the smoky blackish apex, traces of the postmedian shadow and the oblique basal band which is deep brownish-black like the thorax. Abdomen golden ochreous. The larger ♀ is paler, with a broad brownish postmedian nebulous band and discal spot, feebly marked also on the hindwing. Mexico.

hamata. **H. hamata** Schs. (112 g) is extremely similar to *acuta*, darker purple brown with faint traces of a postmedian line before the nebulous stripe and a very indistinct small discal spot. Abdomen less bright ochreous, more sooty brownish, anus reddish ochreous. Guatemala; Costa Rica.

H. petena Schs. (112 g) resembles *hamata*, thorax almost black, abdomen dark brown, only the anus *petena*. rusty red; forewing dark brown with a slight carmine tint, the double postmedian line shadow-like as in *hamata*. Hindwing in the inner-marginal portion pinkish-brown, at the base with ochreous hair. Abdomen of ♀ olive-brown with yellow hair, wings as in *acuta*-♀ more distinctly marked. From a great number of cocoons in a large common web the imagines crept out during a period of 2 years. Guatemala.

H. tapareba Ky. i. l. ? (112 g) is dark brownish-grey, the postmedian line quite obsolete, at the cell-end *tapareba*. with an oval brownish-grey ring filled with yellowish and with a dark centre; both the transverse lines are sometimes feebly bordered with yellowish-white. Abdomen sooty ochreous brown. Guiana, Amazons. The species, which is in the British Museum, seems to have been never described.

H. tapabex Dyar (112 g) is on the forewing, particularly basad, lighter than *tapareba*. with traces of 3 *tapabex*. indistinct slightly darker transverse shadows, the discal spot as in *tapareba*. Abdomen of a brighter ochre colour, ventrum rusty yellow, with a brownish-grey lateral stripe. The ♀ is purple brown, forewing with an angular apex, at the base darker, with a large discal spot and a broad straight distal band. Venezuela, Colombia.

H. dyarex Schs. Head and abdomen ochreous, thorax brown. Forewing loamy brownish as far as the *dyarex*. antemedian line which meets the postmedian line at the inner margin, the area behind it below vein 4 somewhat darker brown, above purple grey; at the cell-end a dark streak broadly edged with loamy whitish. Hindwing whitish-grey, basad and at the inner margin with dull yellowish scales, with a fine dark discal streak. Expanse of wings: 45 mm. Quirigua (Guatemala).

H. rosacea Schs. Head and thorax yellowish olive brown, abdomen dark brown, with ochreous hair. *rosacea*. Forewing pink with the usual dark olive brown basal oblique band, the veins in the marginal area finely brown, at the cell-end with a large olive brown oblique spot; posterior transverse line fine dark, at the margin a brownish shadow ending pointed at the margin on vein 3 and touching the postmedian line below 7. Hindwing pink, at the inner margin darker with a fine postmedian line and a feeble subterminal shadow. Expanse of wings: 46 mm. Costa Rica.

H. thaumex n. sp. (112 g) is very similar to *rosacea*, but more lilac pink, anterior body and the basal *thaumex*. oblique band deep dark brown like the narrow oblique discal spot, the almost straight postmedian line very distinct, with a feeble antemedian line vertical to the inner margin; behind the postmedian line the whole marginal area is dark brownish-grey, at the apex parted by a whitish conspicuous spot, only at the anal angle before and behind the subterminal band, which is only here visible, lighter like the ground-colour. Hindwing somewhat greyer than the forewing, at the inner margin with pink hair, and with 2 feeble darker postmedian shadowy lines. Abdomen ochreous, with blackish-brown bands. Western Colombia (Type in Coll. NIEBELT). *teratex*. — **teratex** f. n. (112 h) may be a form of it, somewhat smaller and instead of the lilac pink colouring ash-grey, the conspicuous greyish brown discal spot larger; the thorax is blacker, the ochreous abdomen with hardly darker bands. Surinam; 4 ♂♂ presented by SCHAUS to the Berlin Museum, where the type is too.

H. subfasciata Dogn. likewise belongs yet near *hamata*. Body brown, base of abdomen with some *subfasciata*. ochreous hairs. Forewing earthy ochreous grey, basad and in the inner-marginal half somewhat lighter, the basal oblique band brown; the fine antemedian line is hardly visible, interrupted below the cell, the postmedian line darker, parallel to the margin, behind it a feeble subterminal shadow, at the cell-end a dark streak, the apex somewhat darkened. Hindwings likewise darker, with 2 postmedian transverse lines. Beneath the two postmedian lines are inclined to form a darkened band, whereby the species is easily separated from *hamata*, beside the different colouring. Expanse of wings: 48 mm. Southern Peru (Chaquimayo).

H. lilacina Dogn. described according to but 1 female has light lilac wings, the forewing and hindwing *lilacina*. only with an obsolete hardly visible discal spot, the forewing without any transverse lines, the hindwing with 2 parallel, rounded, feeble postmedian lines. Centre of thorax ochreous brown, patagia lilac, abdomen brown. French Guiana.

H. tiphys Dogn. Anterior body blackish-brown with single ochreous hairs, abdomen bright ochreous, *tiphys*. ventrum brown. Forewing violet-blackish with darker veins, with the usual blackish-brown basal oblique band and on the cross-vein an intense blackish-brown indistinctly defined strigiform spot; behind the middle two very feeble shadowy lines parallel to the distal margin; marginal area in the lower half and at the apex lighter. Hindwing without distinct transverse lines, but the space between the two lines somewhat lighter. Sao Paulo (Brazil).

H. gracilex Dogn. (112 h) is a smaller species allied to the preceding ones, the apex of the forewing *gracilex*. somewhat less falcate. Thorax brown, abdomen ochreous. Forewing pinkish or lilac grey, marked brownish; the forewing with the usual brown basal oblique band, a discal shadow and a feeble postmedian line behind it, the feeble subterminal shadow vanishes in the darkened apex which shows a small lighter spot. Hindwing with 2 feeble postmedian transverse lines. Amazons (Sao Paulo de Olivença).

H. mymex Dyar (112 h). Thorax black, abdomen ochreous brown, with blackish-brown rings. *mymex*. Forewing hardly falciform, purple brownish or more lilac pink, at the apex darkened; the anterior transverse

line is most distinct in the cell, whereby a cellular streak is produced parallel to the discal streak, basally removed below the cell; postmedian line very intense, almost straight, the subterminal band extinct. Hindwing with 2 shadowy bands in the middle and before the margin. Colombia.

violax. **H. violax** *sp. n.* (112 h). Forewing lilac with brown markings, basal area shaded, the antemedian line broad, basally removed below the median vein, submedianly flawed, much more oblique to the inner margin, inwardly bordered by light. Discal spot shaded, touching the slightly bent postmedian line which is triangularly widened at the costal margin, outside in its entire length slightly bordered with rusty yellowish; subterminal shadow feeble. Hindwing with a small discal spot and 2 feeble shadowy lines. Thorax blackish-brown, base of abdomen rusty red like the base of the hindwing, abdomen above blackish, beneath and at the end reddish-yellow. Type: 1 ♂ from Passa Quatro (Sul de Minas), Southern Brazil; in the Coll. HOPP, Charlottenburg.

d) In the following group the dark brown basal band is absent.

bolivex. **H. bolivex** *Dogn.* (112 h). Thorax brown, base of abdomen with a rosy or brown tint, abdomen above black, beneath and at the end bright golden ochreous. Forewing pinkish-brown, with broad brown transverse lines which are nearer together, a brownish base, a broad subterminal shadow and discal spot, the margin between 7 and 4 brownish. Hindwing somewhat lighter and more pink, with 2 postmedian shadowy bands parallel to the margin. The much larger ♀ is more lilac grey, the abdomen ochreous grey. Peru and Bolivia.

ernestonis. **H. ernestonis** *Strd.* (114 f). Of this doubtful species which was described according to but one ♀ I only know the figure of the type, according to which the species seems to be allied to *bolivex*. Brownish-grey, basally and at the inner margin darkened, the discal spot like a horizontal T, the foot distally prolonged to the almost straight postmedian line; the subterminal line is a distinct straight notched line, narrowly darkened at the margin. Hindwing with 2 postmedian arcuate lines, the postmedian line widened, the subterminal line narrower.

minasia. **H. minasia** *Schs.* (112 h). Thorax purple brown, with cinnamon-red hair, abdomen above black, beneath and at the anus rusty brown. Forewing lilac, basal area darkened brownish, the brownish transverse lines more or less distinctly double, the subterminal shadow violet-grey, discal spot brownish. Hindwing of a purer pink, at the margin somewhat greyer with feeble postmedian and submarginal lines. Brazil, Paraguay.

macellex. **H. macellex** *n. sp.* (112 h) is very similar to *minasia*, larger, with broader wings; pinkish-grey, shaded with dark purple brown as far as the postmedian line, at the costal margin densely dusted with bluish-white, the anterior transverse line somewhat darker, rather straight, close at the small oval, somewhat lighter centred discal spot; postmedian line broad, shadow-like, towards the margin eoneave, between it and the broad subterminal band a lighter band crossed by the slightly darker veins, at the apex a small light spot; base of inner margin with ochreous hair. Hindwing pinkish ochreous, the inner line near the centre, feeble, the exterior line near the bluish-grey margin, broader. Abdomen black, base, ventrum and end reddish yellow. Type: 1 ♂ from Sao Paulo in the Berlin Museum; another ♂ from S. Bernardino, Paraguay, in the same museum.

wagneri. **H. wagneri** *Bouv.* is unknown to me, ranged here by the author. Distal margin slightly concave, thorax in front reddish ochreous, the rest brownish-violet with ochreous hair, the centre of the abdomen blackish, the other parts pinkish ochreous. Forewing light lilac-pink at the costal margin and base, the rest lilac greyish-yellow; anterior transverse line indistinct, behind it a small brownish-violet cross-vein spot; postmedian line double, the interior portion broad, ochreous, the exterior portion less clear, violettish ochreous, behind it a sinuate lilac subterminal band. Hindwing very light pinkish-white, with a darker distal band. In the ♀ the forewing is claret-coloured brick-reddish, the hindwing lighter. Larva brown with light yellow bands and tufts of large ramulous hairs: it lives on a Melastomaceae: Tibouchina holosericea, and pupates in a reddish-white cocoon. Organ Mts.

sorana. **H. sorana** *Schs.* (113 a). Forewing light brownish-pink, thorax and markings dark brown; anterior transverse line below the cell removed far towards the base, submedianly once more angled, cellular spot large, indistinct; posterior transverse line very strong, almost quite straight, right behind it the slightly darker subterminal shadow begins, receding above the middle in a basally concave bow and forming below it 2 sinuous projections towards the margins, the margin darkened into the concavity of the subterminal line. Hindwing greyer, blackened at the inner margin with 2 postmedian shadowy lines, the interior one being more distinct. Abdomen above black, beneath and at the end ochreous. Brazil (Sao Paulo).

lilax. **H. lilax** *Dogn.* (113 a). Forewing pinkish-brown like the thorax, patagia violettish-grey, transverse lines and discal spot dark red-brown, the former broad, on the averted sides bordered with lighter lilac; subterminal shadow feeble, distally light, dentate. Hindwing more pink with 2 redbrown postmedian shadowy lines. Abdomen above black, at the base carmine-brown, laterally and beneath ochreous. The ♀ is much darker purple lilac. Brazil (Amazons. Sao Paulo).

margarita. **H. margarita** *Dogn.* (113 a) is very similar, lighter and softer pinkish lilac, the markings very slightly darker and hazy, thorax rusty brown, abdomen above deep black. Hindwing lighter pink, at the margin somewhat darker. Guiana, Venezuela.

H. novex *Dogn.*, founded upon but one fresh ♀ and a worn ♀, is above greyish-brown with a lilac tint *novex*. and lighter transverse lines, the anterior line oblique, at the costal margin 14 mm, at the inner margin 8 mm distant from the base, the posterior line parallel to the margin, the median area between them somewhat darker, only around the discal spot lighter; at the apex and in the lower marginal half brighter. Hindwing more brownish with a dark discal spot and traces of two light transverse lines. Expanse of wings: 74 mm. Amazons and Peru.

H. olivenca *Schs.* (113 a). Blackish ashy grey, in the median area darker, enclosing traces of a darker *olivenca*. discal spot; transverse lines broad, very light and almost straight; subterminally, as in *novex*, in the lower half lighter and at the apex a whitish spot. Hindwing much more monotonous, the light lines very indistinct. Abdomen greyish ochreous intermixed with long whitish hairs. The larger ♀ is more scantily scaled, lighter, the postmedian line very broad. Amazons, Colombia, Ecuador, Peru. Very similar to *novex*, larger, the discal spot is confluent with the somewhat darker interior border of the postmedian line, whilst in *novex* it is distantly separated.

H. natex *sp. n.* (113 a) is quite a different insect, very conspicuous by the almost unmarked creamy- *natex*. white colour of the ♂, with the same feeble brownish marking as in *olivenca*; shape of wings somewhat broader, the apex more rounded, slightly smoke-coloured, without the light apical spot. Hindwing without markings, almost purely white. Another ♂ is all white, without any traces of markings. The ♀ is more scantily scaled and more grey, the body feebly yellowish. Described according to 2 ♂♂ and 1 ♀ from the Rio Pachitea, Porto Alegre (Rio Grande do Sul). Types in the Berlin Museum.

H. terrosex *Dogn.* Thorax dark brown, abdomen intermixed with lighter hairs. Wings light earth- *terrosex*. brown, with extinct darker brown markings; forewing in the basal third darker, subcostally as far as the centre of the cell strewn with white; at the cell-end a large faded shadowy spot; the anterior transverse line marked by white strewing, the posterior line is a broad faded band, inwardly strewn with white, distally passing over directly into the subterminal shadow; apex somewhat darker. Hindwing with a discal shadow and feeble traces of two postmedian lines. Expanse of wings: 55 mm. Ecuador.

H. pluto *Dogn.* is very similar to *terrosex*, but larger and beneath on the hindwing with but one *pluto*. transverse line. Expanse of wings: 62—66 mm. Bolivia (Rio Songo).

H. palcazua *Schs.* (113 b). Thorax brown, abdomen somewhat lighter, intermixed with yellowish hairs. *palcazua*. Forewing of ♂ cinnamon-brownish with a small dark discal spot and a broad postmedian shadow in a slight S-curve, touching a costal-marginal shadow on vein 6; marginal area lighter grey with a fine dark subterminal line and a darker marginal shadow between 8 and 3. Hindwing with a dark discal spot and traces of two darker lines behind it. The larger ♀ is more monotonous. Eastern Peru; Rio Grande do Sul.

H. nigradorsata *Dogn.* (= *murmur* *Dyar*) (113 b). Body deep black, intermixed with white hairs, anal *nigradorsata*. end light ochreous. Forewing light lilac grey with broad brownish-grey transverse lines, the interior line interrupted below the cell, the exterior one feebly bent, touching the intense discal spot; subterminal shadow in the upper half extending obliquely inward, below it with the two usual projections between 2 and 4; marginal area very light, only darkened in the upper half. Hindwing somewhat darker with two parallel postmedian transverse bands. Peru, Bolivia.

H. roseata *Dogn.* (113 b) is somewhat similar to the foregoing species, but the forewing is longer, the *roseata*. apex more produced, the black colour of the body is intermixed with pinkish claret-coloured hairs, the colour of the wings is lilac pink, with the same markings, but on the hindwing the two transverse lines are equally strong and equidistant from each other and from the margin, in *nigradorsata* the postmedian line is stronger and the subterminal line is nearer to the margin. The species is also somewhat larger, the ♀ grey, scantily scaled. Colombia; Pacho; Monte Tolima.

H. bouvereti *Dogn.* (113 b) is monotonously greyish-brown, the body somewhat darker, the anal hair *bouvereti*. intermixed with a few yellowish hairs. Forewing with two broad whitish transverse bands without a distinct discal spot, only the cross-vein being more prominently dark. Hindwing with a broad faded light median band. Ecuador and Colombia.

H. mixtipler *Dogn.* (= *multiplex* *Dogn.*) (113 c). Anterior body sooty black, abdomen somewhat *mixtipler*. browner with ochreous anal hair. Wings sooty blackish with darker transverse lines and fine white hairs which in some places form dense lines; at the cell-end a large faded spot touching the postmedian line which runs slightly concave to the inner margin and is distally strewn with whitish; at the apex, subterminally in the centre and terminally at the anal angle whitish spots. Hindwing scarcely lighter with traces of two dark postmedian lines. Peru (Yahuarmayo).

H. frigida *Schs.* (113 c). Anterior body blackish-brown, abdomen above black, with lateral and anal *frigida*. ochreous hair. Forewing purple blackish with darker brown veins, an indistinctly darker basal shadow and a blackish median area which may be defined by darker lines which, however, may also be absent; the interior border is almost straight, the exterior border obliquely inward, somewhat excurved below the costal margin;

at the cell-end a dark strigiform spot; the dark subterminal shadow is indistinct and irregular. On the hindwing only the darker veins and a very feeble subterminal shadow are noticeable. The black ♀ shows hardly any marking. Guatemala; Costa Rica.

vittex. **H. vittex** *sp. n.* (113 c) is very similar to *frigida*, smaller, lighter yellowish-grey, the median area more distinctly prominent, brownish-grey, the interior border not straight but submedian, not on the median vein, inwardly projecting in a right angle, in the cell fused with the discal streak. Hindwing with a broad, straight dark median band. Body blackish, but very thickly covered with rusty yellow hairs, so that only the abdomen above shows through dark. Guatemala. According to 2 ♂♂; type in the Coll. HOPP-Charlottenburg.

pauper. **H. pauper** Dyar (113 c) has somewhat narrower wings than the preceding species, with a somewhat more produced and slightly falcate apex of the forewing; light drab, transverse lines very feebly whitish; a very conspicuous white spot in the cell before the slightly darker discal spot, and a whitish apical spot. Abdomen somewhat ochreous. Colombia; Peru.

medifex. **H. medifex** Dogn. resembles *frigida*, but it is somewhat smaller, lighter drab, and distinguished by a very narrow lighter median band which is only 2 mm broad at the inner margin, 5 mm at the costal margin and contains a still darker discal spot; apical area down to vein 4 somewhat darkened. Hindwing in the marginal third somewhat lighter with a feeble indistinct discal streak and a subterminal band which is only visible in a certain exposure to light. Described according to a ♂ from Pacho (Colombia).

terranea. **H. terranea** Schs., described only according to a ♀, is monotonously dark brown, scantily scaled, no markings except faint traces of a discal spot. Abdomen laterally with ochreous hair. Expanse of wings: 53 mm. Petropolis (Brazil).

leilex. **H. leilex** Dyar is drab, shaded somewhat blackish, with fine darker veins, with a large round dark discal spot and small irregular shadowy spots instead of the subterminal line, the other transverse lines being absent. Expanse of wings: 40 mm. Peru.

ascodex. **H. ascodex** Dyar is similar to *leilex* but of a softer drab colour, without the blackish shading, on the forewing only with a large feeble discal spot and traces of the undulate-dentate distal border of the subterminal line. Hindwing with two feeble darker distal bands. Abdomen with ochreous hair. Expanse of wings: 40 mm. Peru.

metabus. **H. metabus** Cr. is said by SCHAUS to belong to this place; the insect is unknown to me, CRAMER's figure representing a brown ♀ without any markings is difficult to determine. Surinam.

athlia. **H. athlia** Dyar (113 c) has broader wings than the preceding species, the apex of the forewing is more rounded, the abdomen with brownish ochreous hair. Wings drab with a slight brownish tint and a broadly darkened discal spot; transverse lines broad, light, convergent to the inner margin, but the interior one more or less extinct, the marginal area behind the subterminal line somewhat lighter with a prominent whitish apical spot. Hindwing with a feeble dark cellular spot and only a light distal line which is slightly darker on both sides. Peru; Bolivia.

individiosa. **H. individiosa** Dyar is very similar to *athlia*, somewhat smaller, the apex of the forewing not rounded, the markings less distinct, the transverse line of the hindwing straighter and nearer to the cell. Expanse of wings: 32—34 mm. Panama.

valvex. **H. valvex** Dyar (113 c, d) is a larger species, with a blackish-brown front body, the abdomen with ochreous hair. Wings lilac grey with a sooty brown tint, basal area broadly darkened, the broad faded postmedian band directly passes over into the subterminal band the discal border of which is almost straight; in the lighter median area a faded discal spot. Hindwing with a discal spot and 2 distantly separated postmedian shadowy lines. The ♀ is still more indistinctly marked. Guiana, Amazons.

umbratula. **H. umbratula** Dyar (113 d). Head and thorax ochreous brown, abdomen lighter ochreous. Forewing reddish lilac brown, transverse lines brown, both broad and uniform, the subterminal line undulate, irregular, narrow and extinct. On the hindwing the interior line is distinct, the exterior one faded, with a discal spot of medium intensity. Allied with *valvex* and *umbrata* Schs., but lighter and of a pink ground-colour instead of grey. Teapa (Tabasco, Mexico), Guatemala.

latex. **H. latex** *sp. n.* (113 d) may belong to this place. One female from Venezuela (Valencia) shows a marking similar to *approximans*-♀, but the wings are much broader, the apex is quite round, the costal margin of the hindwing much longer, the inner margin shorter than in *approximans*-♀. Ground-colour brownish-grey, with fine dark veins, basal area darkened, discal spot longer, but narrower than in *approximans*, the postmedian and subterminal bands forming a coherent broad dark area, below the costal margin turning rounded towards the base with its interior half, whilst the exterior half extends straight on towards the apex, so that a lighter triangular spot is enclosed. Discal spot of hindwing small, shortly behind it the whole subterminal and marginal area is darkened. Type in the Berlin Museum. A similar ♀ without denomination in the U.S. Museum of Washington. Another ♀ from Muzo, Colombia, in the Coll. HOPP-Charlottenburg.

H. approximans *Wkr.* (= *pollex* *Dyar*) (113 d). Head and thorax brownish-grey, abdomen intermixed with ochreous hairs. Forewing lilac brownish-grey, basal area darkened, without a distinctly prominent antemedian line, with a large extinct discal spot; the broad faded postmedian band slightly separated from the subterminal band by a faded lighter interspace. On the hindwing with a small discal spot both the lines are united into an indistinct broad band. Panama, Venezuela. *approximans.*

H. darlingi *Dyar* (113 d) is very similar to the preceding species, the collar of a brighter ochre colour, the markings less bright and contrasting, the costal-marginal portion lighter than in *approximans*, the discal spot more shaded, the abdomen somewhat more brownish. Larva with a cerise head, whitish with black angular markings and spots, whitish thorns with light branches; it lives on the Cachu tree (*Anacardiaceae*). Panama. — **H. tendex** *f. n.* (113 e) is presumably a southern form with narrower more elongate wings with a more produced apex, ground-colour more lilac, more contrastingly marked, the discal spot thicker, rounder, with broader transverse lines, but the subterminal shadow much narrower and paler, the apical marginal shadow broader, the small white spot in it much smaller. Hindwing more triangular with a longer anal angle and a straight margin, distinct discal spot, the two transverse lines much more separated, the interior line almost straight, close at the discal spot, the exterior line broader, close at the margin. Abdomen lighter yellow. Type: 1 ♂ from the Rio Pachitea, Porto Alegre (Rio Grande do Sul). — A very similar form with still narrower forewings, a more oblique distal margin and a narrower postmedian line, from Surinam, shows the transverse lines of the hindwing much closer together: — **H. guayanensis** *f. n.* (113 e). *darlingi.* *tendex.* *guayanensis.*

H. lilacinex *sp. n.* (113 e) is intermediary between *darlingi* and *umbrata*, larger than the latter, with a more pointed apex of the forewing, the forewing quite light lilac grey, basal area darkened as in *darlingi*, the lower end of the large discal spot touches the postmedian band which is somewhat narrower than in *umbrata* and likewise bifurcates Y-like between 6 and 7. Subterminal band light as in *tendex*, but somewhat broader, the light apical streak narrow and distinctly contrasting. Hindwing darker sooty blackish, the two transverse lines distantly separated, narrow, the interior line close at the cellular streak, behind the distal line the marginal area is narrowly lighter lilac. Abdomen yellowish ochre, collar with long yellowish hair. According to a ♂ from Balzapamba (Ecuador); type in the Coll. Hopp-Charlottenburg. *lilacinex.*

H. umbrata *Schs.* (113 c) is closely allied to the two preceding species and variable, but discernible by the very broad postmedian band which is distinctly separated from the subterminal band. Thorax lilac brown, strongly haired ochreous, abdomen ochreous. Forewing dull pinkish lilac brownish, basal area darkened, bordered by the antemedian line, discal spot large, distinct, more prominent than in the preceding species. Hindwing with fine dark veins, the two lines separated. Guatemala; Costa Rica; Colombia. *umbrata.*

H. murex *Dyar* (113 e, f) is a smaller species with somewhat falcate forewings, drab, thorax somewhat darker, abdomen with ochreous hair, the transverse lines almost quite obsolete, the exterior one somewhat better marked at the costal margin, with a small light spot behind it; subterminal line broadly shaded, nearing the margin between 2 and 4. Hindwing between the two lines and before the margin somewhat lighter. Surinam. *murex.*

H. nigripes *sp. n.* (113 f) is somewhat similar, smaller, more slender, apex more produced, the small hindwing rounded. Forewing purple blackish, marked darker smoky black; basal area darkened, the postmedian line confluent with the subterminal shadowy band which projects but little between 2 and 4; the dark discal streak in a dark shadowy spot. Hindwing without the discal spot, with 2 shadowy bands which are distantly separated, the interior line extends through the cross-vein. Abdomen golden ochreous brown, with blackish bands. Tibiae and tarsi black. Muzo (Colombia); type in the Coll. Hopp-Charlottenburg. *nigripes.*

H. cedomnibus *Dyar* to a certain degree resembles *pauper* and *athlia*; it is larger and the forewing is more quadrangular not falcate at the apex, light drab, with somewhat lighter obsolete transverse lines, the absent discal spot is indicated by a light cellular spot before it, at the apex another whitish spot. Hindwing quite indistinctly marked, the marginal area somewhat lighter with an irregular interior border. Carabaya (Peru). *cedomnibus.*

H. pachobex *Dogn.* is likewise very similar to *athlia*, forewing less rounded, margin more oblique and straighter, postmedian line correspondingly also more oblique and nearer to the discal spot. Ground-colour less blackish, but in the ♀ blacker; ♀ more marked, beside the two light transverse lines another median line. Pacho (Colombia). Expanse of wings: ♂ 44, ♀ 60 mm. *pachobex.*

H. schausi *Dyar* (113 f). Lilac grey, with a slight (in the ♀ somewhat more) rosy tint, abdomen with ochreous hair. Forewing with somewhat lighter transverse lines, the distal line near the discal spot and inwards band-like dark, narrowing down towards the inner margin; behind the indentation of the subterminal line in its upper half dark marginal filling with a small whitish apical spot. Hindwing with 2 feeble distal lines without a discal spot. Venezuela; Guiana; Peru. *schausi.*

H. canitia *Stoll* (113 f) is very similar to *schausi*, larger, with narrower wings, with an oblique distal margin, of a greyer colour, more intensely marked, the cell before the discal spot light, basal area dark, the distinct antemedian line bordered with light towards the base, subterminal line more distinct. On the forewing the lines are represented by two shadowy bands. The ♀ is much larger and greyer. Venezuela; French and Dutch Guinea. *canitia.*

- composita*. **H. composita** Dogn. (113 f). Blackish-grey with a slightly darker median area, the transverse lines bordering on it still more distinct, the interior line inwardly interrupted below the cell, both bordered with lilae whitish on the averted sides; at the cell-end another darker spot; subterminal band of the usual shape, towards the margin accompanied by a whitish brightening; the bands on the hindwing narrower than in *canitia*. Merida (Venezuela).
- egrex*. **H. egrex** *sp. n.* (113 g) in the scheme of markings recalls *composita*, but it is twice as large, with a more prolonged apex, shape more that of *indurata*, suffused with lilac pink, with a very large contrasting discal spot, basally at the inner margin below 2 darkened brown; between 4 and 7 the distal subterminal border forms a straight shadowy line towards the apex. Thorax blackish brown, in the centre light grey. Abdomen above black, basally with pinkish ochre hair, laterally, beneath and at the end bright rusty yellow. Type: 1 ♂ from the Chaco, La Paz (Bolivia) from an altitude of 3000 m in the Coll. STGR. (Berlin Museum).
- obsoleta*. **H. obsoleta** Stoll is hardly determinable from the figure; a ♀, light lilac pink with 3 oblique broad light bands, without the discal spot. Surinam. SCHAUS places the species here.
- oroyex*. **H. oroyex** Dogn. (113 g) is near *composita*, a little more brownish, abdomen of a brighter ochre, the markings less contrasting, the two transverse lines distantly separated, but on the hindwing nearer together.
- amazonica*. Merida (Venezuela); we figure a co-type from the Coll. DOGNIN. — **amazonica** *f. n.* (113 g) is probably the same species according to SCHAUS; larger, more lilac grey, with fine dark veins, discal spot much larger. Type from S. Paulo de Olivença (Upper Amazons) in the Berlin Museum.
- indurata*. **H. indurata** Dyar (113 g) is of a more slender structure, with a produced, slightly falcate apex of the forewing, lilac grey with a faint pink tint, abdomen brownish, laterally and at the end light ochreous as at the base of the hindwing; transverse lines rather near together, the anterior line in the cell close at the discal spot, the posterior line flatly concave, acute-angularly bent below the costal margin at which it begins with a large triangular shadowy spot; marginal area in its upper half darkened with a proximally convex bow. Lines of hindwing rather close together. French Guiana.
- mystica*. **H. mystica** Dyar is closely allied to *composita*, forewing at the apex rounded, shaded darker on the lilac grey ground, the light transverse lines feeble, between them an obsolete narrow shadowy spot; marginal area lighter, in the upper half with a rounded marginal shadow. Hindwing with a lighter band in the distal third, the lines bordering on it hardly or not visible. A small species with an expanse of 32 mm, the ♀ being 45 mm large is still darker shaded, the abdomen covered with ochreous hair. Guiana; Trinidad.
- andrei*. **H. andrei** Dogn. (= *grisoli* Bouv.) (113 g) is somewhat like *canitia*, smaller, brownish-grey, abdomen with ochreous hair; transverse lines whitish, at the costal margin somewhat expanded, the interior line in the cell close before the discal spot, receding far below the cell, at the inner margin only 1 or 2 mm distant from the posterior line, the light spotted distal border of the subterminal line at the anal angle and apex removed to the margin. Hindwing with 2 light distal lines. Apparently widely distributed; from Guiana, Venezuela, Amazons, and Peru.
- vindex*. **H. vindex** Dyar (113 f, g). Black, abdomen excepting base dark ochre; forewing with a very large black discal spot and whitish transverse lines being convergent towards the inner margin; the light submarginal shadow between 5 and 7 more or less interrupted. Hindwing with a round obsolete discal shadow and light
- solvex*. postmedian and marginal bands. A common species from Southern Brazil. — **solvex** Dyar may be only a smaller form in which the light postmedian line shows a darker interior border touching the discal spot. From Rio Grande do Sul.
- angulex*. **H. angulex** *sp. n.* (113 g) is allied to *vindex*, though not black but greyish-brown, the abdomen scantily intermixed with ochreous hairs; it is well characterized by the antemedian line being distally interrupted below the costa, proximally bordering on the discal spot in the cell, below it interrupted far basad, extending obliquely distad to the inner margin. Type, a ♀ from Pebas (Amazons), in the Berlin Museum; ♂ type from Minas Geraes in the Coll. HOPP-Charlottenburg.
- fulviventris*. **H. fulviventris** Berg (113 h). Front body lilac grey, abdomen black, beneath, laterally and at the end bright ochreous. Wings lilac grey, in the basal half shaded brownish, enclosing the brown antemedian line which is inside bordered with lilac grey, discal spot brownish, shadow-like; the posterior transverse line is distinctly dark brown, almost straight, on its outside the brown subterminal shadow is closely adjacent; marginal area lilac grey, in the upper half shaded with brown. Hindwing lighter with 2 feeble transverse lines. The ♀ is
- oralex*. more blackish, but more obsoletely marked. Southern Brazil, Argentina. — **oralex** Dyar is probably only a somewhat darker form, or the same as the typical form.
- remex*. **H. remex** Dyar (113 h). Thorax dark grey, abdomen mixed with dull ochreous hairs. Forewing lilac grey, basal area only feebly shaded, without a distinct antemedian line, discal spot elliptical, the straight postmedian line distinct as in *fulviventris*, the subterminal shadow narrower and straighter than usual. Hindwing with 2 lines nearing the margin. Rio de Janeiro. Sao Paulo.

H. caucanex *sp. n.* (113 h) is allied to *remex*, ground-colour almost lilac whitish, abdomen lighter *caucanex*. ochreous, antemedian line distinct, below the cell strongly removed basad, submedianly thicker, the subterminal shadow much broader, anal angle and apical spot very contrastingly light; hindwing with a distinct discal spot, close at it the interior line, the exterior line thrice as broad, shaded darker. Type: ♂ from Popayan, Dep. Cauca (Colombia), co-type: ♂ from Ieononzo (Pandi, Colombia), both in the Coll. HOPP-Charlottenburg.

H. livex *Dyar* (113 h). Thorax brownish-grey, abdomen with ochreous hair. Forewing similar to *livex*. *fulviventris*, lighter brownish-grey, more contrastingly marked, the antemedian line proximad, especially at the costal margin more profusely marked white, postmedian line narrower. Lines on hindwing close together, exterior line broader, with a somewhat irregular distal border. The ♀ has a more faded marking, thorax and abdomen brown, the abdomen laterally and at the end with ochreous hair. It may be *H. subcana* *Wkr.* which was described only according to a ♀.

H. discutex *sp. n.* (113 h) is likewise very similar to *livex* and especially to *fulviventris*, but the abdomen *discutex*. is quite ochreous as in *livex*. Forewing almost exactly that of *fulviventris*, the discal spot smaller and more distinct, the postmedian line not so oblique, somewhat broader and more faded, behind it at the costal margin as small whitish spot, the white apical spot larger and longer, the broad subterminal band receding more between 4 and 7, the brown marginal shadow opposite it broader, reaching the subterminal band between 6 and 7. On the hindwing the two lines are nearer together, the interior one is stronger than the exterior one. ♂ type from Sao Paulo de Olivença, ♀ from Chanchamayo (Peru) in the Berlin Museum. According to SCHAUS a distinct new species.

H. peruvex *sp. n.* (117 a) is near *livex*, larger, much more indistinctly marked, the antemedian line *peruvex*. broadly faded, vertical on the inner margin, in *livex* submedianly distally angular, inwards likewise bordered with whitish, the white in the cell extending to the large discal spot indistinctly coherent with the costal margin, the latter spot touching the broad faded postmedian line on vein 4; behind it especially at the costal margin a spot-like white brightening, also at the apex and behind the subterminal line. Hindwing as in *livex*, but the transverse lines more separated, the interior line crossing the discal spot. Under surface behind the straight postmedian line light, with distinct dark veins. Abdomen more olive yellowish-brown, not ochreous. Type: 1 ♂ from Marcapata (Peru) in the Coll. HOPP-Charlottenburg.

H. vialactea *sp. n.* (114 a) is very similar to the preceding species from which it is at once discernible *vialactea*. by the light violettish-white median area enclosing the large intense oval discal spot; antemedian line not angular, but forming one bow each in the cell and submedianly, below 1 obliquely distad to the inner margin; marginal area as in *fulviventris*. Hindwing with a small discal spot touching the interior feebly curved line. Abdomen brown, only at the end more ochreous. Type: ♂ from the Chaco. La Paz (Bolivia), from an altitude of 3000 m, in the Coll. Stgr. (Berlin Museum.)

H. orbifex *Dyar*. Thorax brownish-grey, abdomen thickly covered with ochreous hair, the brown *orbifex*. ground only showing through on the dorsum. Forewing exactly as in *fulviventris*. Hindwing with a large discal spot, the two lines far behind it, just as dark, but the exterior one much broader than the interior one. Expanse of wings: 38 mm. Rio de Janeiro.

H. discifex *sp. n.* (114 a) is very near *orbifex*, but also similar to *vindex*. Abdomen brighter golden *discifex*. ochreous than in *orbifex*, wings blacker though not so black as in *vindex*: basal area darkened, the transverse stripes broad, somewhat hazy, convergent to the inner margin, behind the distal one at the costal margin a triangular light spot of the ground-colour, the subterminal band, moreover, only separated by a very narrow, blurred line from the postmedian band which is distally less sharply defined. Hindwing with a large discal spot, the lines distantly separated, hazy, the interior one stronger than the exterior one. Type: 1 ♂ from Rio Grande do Sul in the Coll. Stgr. (Berlin Museum).

H. maurex *sp. n.* (114 a) is an entirely sooty black species, the ventral side of the abdomen also black, *maurex*. the markings still deeper black, the transverse lines moderately broad, shaded, the posterior one passing over directly into the broad subterminal shadow. Hindwing with a discal spot and 2 lines, the interior line stronger, touching the spot. ♂ and ♀ from Passa Quatro, Sul de Minas (Southern Brazil); types in the Coll. HOPP-Charlottenburg.

H. muscula *Vuillot* (114 a) is quite a different larger species which may be best ranged after *maurex*; *muscula*. it is also somewhat similar to *Automeris violascens* (114 g), but it does not fit to *Automeris*. Entirely black, thinly scaled, a little more densely in the basal half and the apical part of the costal margin, with a much produced apex of the forewing, a thick, deeper black discal spot and a very feebly marked postmedian shadow obliquely from the apex to the centre of the inner margin. Hindwing with a very faint discal ring-shadow. Abdomen beneath rusty red, above black. The ♀ is still more thinly scaled, diaphanous blackish-grey, the discal spot of the forewing much less developed. Abdomen beneath much darker, only feebly intermixed with rusty brown. Sa. Catharina. Larva on the 4 first rings yellowish-green, from the 4th ring on the venter and sides blackish-grey, from the 5th ring there are laterally large white, oval oblique spots bordered with deep black, from the 5th ring on the dorsum purple red saddle-spots with black longitudinal lines; ring-indentations yellowish-green, of the same colour the branched thorns.

- liturex.* **H. liturex** Dyar (114 a). Near *livex*, smaller and much less contrasting, the postmedian line hazily passing over into the lighter subterminal shadow. Lines of hindwing relatively distant from each other, the distal one nearer to the margin. Guiana, Amazons.
- coëx.* **H. coëx** Dyar (114 a). Thorax brownish-grey, abdomen with ochreous hair. Forewing lilae grey, basad irregularly shaded darker; a small discal spot in the cell and a larger one at the end; the broad distal transverse line straight, shaded as far as the subterminal line. Hindwing instead of the discal spot with the interior line through the cell-end, the exterior line feeble, irregularly shaded. A small species from Venezuela (Aroa, Orinoo), the figured ♂ smaller than the type.
- rex.* **H. rex** Dyar (114 b) differs from *coëx* in its larger size, the more falciform apex of the forewing and darker colouring; the small interior cellular spot is absent, the distal line broader, the following shadow feeble. Hindwing likewise darker, the lines feeble, the exterior one more broadly shaded, the marginal area behind not lighter. Guiana, Amazons.
- nigricans.* **H. nigricans** Berg (114 b) is a somewhat variable species. Thorax dark ash-grey, abdomen ochreous. Forewing varying between lilac grey and brownish, as far as the distal transverse line mostly feebly darker, the two transverse lines blackish, the interior one mostly obsolete, incurved below the cell, the exterior one fine, very feebly curved; discal spot large, blackish, often touching the postmedian line; subterminal shadow feeble, of the usual shape, before it at the costal margin a small more or less light triangular spot, behind it in the upper half the usual marginal shadow. Hindwing sometimes darkened blackish as far as the exterior line, mostly only at the inner margin feebly darker, the two transverse lines distinct, the interior one beneath straight and stronger than the exterior one. The ♀ is dark violettish-grey or blackish-grey, the lines and discal spot broadly shaded with black. Abdomen black, beneath, laterally and at the end densely covered with rusty yellow hair. Southern Brazil; Argentina, Paraguay, Patagonia. The larva is yellow, laterally spotted black, with a black head and long ramified thorns ending on the 3 first rings with black hairs. It lives on Camphoromaea laxa and many other trees and shrubs. Mr. KÖHLER in Buenos Ayres writes me about it besides: *nigricans* is officially declared a vermin in the Province of Buenos Ayres and often strips wide stretches of willows and other plantations. The larva burns vehemently with its burning hairs. It lives together in nests and only separates shortly before the pupation. Few years ago the insects were in such immense numbers in the willow-plantations near the City that the droppings were to be heard drizzling to the ground like rain. Mr. KÖHLER took there also 2 incomplete hybrids being male in general, but darker, with a female black abdomen and little anal wool.
- paulex.* **H. paulex** Dogn. (114 b) is allied to *nigricans*; somewhat larger, the front body dark brown, abdomen ochreous. Forewing drab with a brownish tint, slightly strewn with white, the transverse lines on the averted sides feebly lighter or whitish, like the subterminal shadow on its outside; discal spot rather large and distinct. Hindwing with a somewhat more blackish tint, the cellular spot and both the distal lines feebly marked. S. Paulo.
- biolleya.* **H. biolleya** Schs. (114 b) is more sooty blackish-brown than the preceding species, basally still darker, the anterior transverse line lighter, the posterior line fine dark, outside likewise light-edged, the discal spot quite obsolete, but large; subterminal line as in *paulex*. Hindwing sooty brownish with but one shadowy indistinct postmedian line. Abdomen orange brownish. Costa Rica; Brazil (?).
- mortifex.* **H. mortifex** Dyar. Thorax deep brown, abdomen with ochreous hair and somewhat darker bands. Forewing slightly falcate, lilae grey, densely shaded with dark grey, costal margin in the median area dusted whitish, discal spot large, faded; postmedian line fine, very feebly incurved, subterminal shadow as usual. Hindwing with 2 shadowy lines, the exterior one undulate towards the margin. Expanse of wings: 35 mm. Venezuela.
- lolamex.* **H. lolamex** Dyar (114 b) resembles *nigricans*, but the forewing is more falcate, the discal spot larger, browner and faded, the distal transverse line browner and straighter, gradually vanishing in the brown subterminal shadow. Hindwing above with 2 curved feeble shadowy lines, beneath with 2 feeble curved, distantly separated bands, the interior one not straight and stronger than in *nigricans*. Venezuela.
- molpex.* **H. molpex** Dyar, according to the description, looks exactly like *rex* and is perhaps a form of it; on the hindwing the interior line is situate close behind the feebly visible discal spot. Expanse of wings: 35 mm. French Guiana.
- munonia.* **H. munonia** Schs. Body dark greyish-brown, abdomen cinnamon-reddish. Forewing reddish claret-coloured greyish-brown with a broad lighter subterminal shadow reaching the margin below 4; costal margin before the centre with white hairs, antemedian line light reddish-yellow, irregularly interrupted, the posterior line feebly incurved, brown, distally bordered with olive reddish, proximad with a lighter reddish claret-colour. Hindwing at the costal and distal margins light brownish, in the disc reddish yellowish-brown, thickly clad with dark claret-coloured hair; at the cross-vein a dark double line, behind it the dark postmedian line and a dark subterminal shadow. Expanse of wings: 40 mm. S. Paulo (Brazil).

H. falcifera *Hbn.* (= *myops* *Wkr.*) (114 b). Wings more falciform; brownish, rather variable; the *falcifera*. interior transverse line more or less distinct, acute-angular below the costal margin and here sometimes bordered with whitish, the posterior line very distinct, dull brown, at the costal and inner margins somewhat triangularly thickened, almost straight, only below the costal margin slightly flawed; discal spot elongate, subterminal shadow very faint; in the shading of the upper marginal half a more or less distinct whitish spot. Hindwing in the inner marginal half mostly somewhat blackened, behind the exterior transverse line the margin is somewhat lighter. Brazil.

H. obtusa *Dogn.* is a small species characterized by the obtuse apex and straight distal margin of the *obtusa*. forewing. Front body brown, abdomen rusty yellow. Wings drab, with 2 darker lines, a straight postmedian line being broad on the forewing and running parallel to the margin, and a subterminal line being likewise parallel, but only complete on the hindwing, on the forewing only marked at the costal margin; discal spots scarcely visible; forewing with traces of a lighter marginal line proximally bordering on the darker margin from the apex to 3. Described according to a ♂ with an expanse of 32 mm, from Obidos (Amazons).

H. pallidex *Dogn.*, likewise based upon but 1 ♂ from Uruguay, is light grey, the thorax somewhat *pallidex*. darker, frons, collar and abdomen ochreous. Forewing light grey, apicad somewhat darker, the apex itself with a small light spot, with 2 fine dark transverse lines which are only 1 mm distant from each other at the inner margin, but 8 mm at the costal margin, thus almost forming a V; between them a thick dark discal spot; subterminal shadow intense, disappearing towards the costal margin. On the similarly coloured hindwing the lines are hardly indicated, beneath much more distinct, the exterior line is a broad band. Expanse of wings: 35 mm.

H. croëx *Schs.* (114 c). Head and thorax dark grey, abdomen above brownish yellow, beneath grey. *croëx*. Wings thinly scaled, dull grey, the hardly discernible lines on the averted sides whitish, the posterior line at the costal margin broader; apically a feeble light shadow; a very feeble subterminal brightening; discal spot feeble, shaded. On the hindwing the margin is somewhat lighter behind the subterminal band; the small discal spot is feeble. Guatemala.

H. colombex *Dogn.* (114 c) is somewhat larger than the preceding species and not quite so thinly scaled, *colombex*. the lines are only a very indistinct whitish brightening, a scarcely darker median area encloses the shadowy discal spot; subterminal band very indistinct, touching the postmedian line between 4 and 6. Hindwing with a feeble discal streak and 2 quite indistinct lines. San Antonio (Colombia). It also resembles *inficita* in which, however, the more oblique postmedian line is more remote from the apex at the costal margin, the hindwing being without any lines.

H. tinturex *Schs.* (114 c) likewise resembles the two preceding species, but the ground colour is more *tinturex*. of a dull pinkish lilac, the very faint antemedian line is whitish, the postmedian line broad and fadedly darker, the subterminal area with hardly any marking. Hindwing with a broader median shadow and a narrow subterminal line. Guatemala.

H. humilis *Dogn.* (114 b) may be only the Amazons-race of *colombex*, somewhat smaller than the latter, *humilis*. the abdomen lighter yellowish, greyer, the transverse lines at the costal margin bordered with a more whitish shade. Sao Paulo de Olivença (Amazons).

H. inficita *Wkr.*, as mentioned above, is said to be very similar to *colombex*, but the postmedian line is *inficita*. more remote from the apex at the costal margin, more oblique and soon ends below the costal margin; the marginal line is also farther away from the distal margin. Hindwing without any lines. Brazil; Costa Rica (?).

H. alinda *Drc.* (114 c) is a more slender species with a produced falciform apex, the ground colour most *alinda*. variable from an almost pure pink with all tints to brownish or lilac grey, the transverse lines broad, somewhat faded, on the averted sides mostly somewhat lighter, with an obsolete discal spot and a more or less distinct subterminal band. Hindwing with 2 faint transverse lines. Guatemala, Costa Rica. — **colombiana** *Dogn.* *colombiana*. (114 d) is larger and more contrasting, the postmedian line straighter, otherwise coloured and marked the same. From Costa Rica to Eastern Colombia. — **pernex** *f. n.* (114 d). In Western Colombia the species is represented *pernex*. by a still more slender form with a still more produced apex of the forewing and a higher shape of wings owing to the longer distal margin. Almost of a pink flesh colour, the two transverse lines more parallel, therefore the median area at the inner margin much broader, the subterminal band narrower, the light apical spot long and distinct. Hindwing more triangular, the transverse lines nearer together and straight. Type: 1 ♂ from Bella Vista (Western Colombia) in the Coll. NIEPALT.

H. zonex *sp. n.* (114 d) is allied to *alinda*, forewing narrower with a more produced apex, hindwing *zonex*. almost triangular, with an acute-angular anal angle and a straight distal margin; ground colour light violettish-grey, strewn with white, especially basad, at the costal margin and anal angle; the two transverse lines close together, forming a narrowly triangular dark median band which encloses the faded discal spot; subterminal and marginal markings the same as in *alinda colombiana*. Hindwing more blackish, behind the indistinct distal transverse line lighter reddish, with a faint discal streak. Abdomen with ochreous hair and blackish bands. Legs not pink. Colombia. Type: 1 ♂ in the Coll. HOPP-Charlottenburg, from Icononzo (Pandi).

- chirex*. **H. chirex** Schs. (114 d). Front body lilac brown, abdomen with ochreous hair, with blackish-brown ring indentations. Wings pinkish lilac brown, the lines faded, the antemedian and postmedian lines broadly flown together at the inner margin, at the cross-vein a dark shadowy streak; subterminal line distally feebly bordered with a lighter colour. Hindwing with 2 almost straight median and postmedian shadowy lines. Guatemala.
- colimatifex*. **H. colimatifex** Dyar (114 d) is similar to *chirex*, pink with a faint orange tint, the lines not contrasting. the posterior line straight, united with the discal spot; subterminal band distally bordered with a lighter pink. Hindwing with 2 straight dark bands. Body more orange pink. Mexico (Colima).
- rubrifrons*. **H. rubrifrons** Schs. (114 d) is more pinkish lilac, with fine darker veins, the exterior transverse line passes over into the broad subterminal shadow which is distally bordered with a lighter colour. Hindwing with a faint discal streak and feebly visible lines, the interior one somewhat angular. Frons and legs of a bright crimson colour. Costa Rica. — **H. muzoensis** f. n. (114 e) is much more distinctly and contrastingly marked, the lilac pink median area broader, the broad distinct postmedian line separated from the somewhat lighter subterminal shadow by a narrow light lilac line, between 5 and 7 confluent with the very dark marginal spot; on the hindwing both lines are very distinct. Abdomen ochreous without blackish bands, with lilac pink dorsal hairs. Perhaps a distinct species. Muzo (Colombia); type: 1 ♂ in the Coll. HOPP-Charlottenburg.
- multiplex*. **H. multiplex** Schs. Pinkish-brown, body densely covered with pinkish-brown hair; antennae brown, not yellow. Apex of forewing scarcely falciform; pinkish-brown with darker lines; basal area darkened; exterior transverse line broad, touching the discal spot on vein 3, subterminal band feebly shaded darker, the apical marginal band darker. Hindwing with 2 fine curved lines and a narrow discal spot. Expanse of wings: 48 mm. Costa Rica.
- dalina*. **H. dalina** Schs. (114 e) is somewhat smaller than *rubrifrons*, the legs likewise bright earmine, but not the frons. On the forewing the median area is very broad, the narrow discal streak isolated, the broad almost straight transverse line near the margin, widened at the costal margin, the subterminal band narrow, separated by a light interspace from the postmedian band, apex with a lighter spot. Hindwing lighter, with hardly any marking. Guatemala.
- dalifex*. **H. dalifex** Dogn. (114 e) is similar to *dalina*, the legs not pink, hindwing with a very slight angle on 3, forewing with an obtusely falcate apex; median area not so broad, postmedian line more oblique, the oblong discal spot larger. Hindwing with 2 distinct lines. Colombia.
- coinopus*. **H. coinopus** Dyar (114 e). Purple brown or lilac pink, legs similarly coloured, not pink, abdomen ochreous brown. Both wings with round, faded though not indistinct discal spots, with a lighter, somewhat undulate distal band which is straighter in the ♀, whilst on the hindwing it is faint in the ♂ and altogether absent in the ♀; only traces of a whitish subterminal line. Mexico (Coatepec). Larva with a mahogany-brown head and a yellowish body which is densely spotted black, so that only undulate dorsal, subdorsal and straight lateral and subventral lines remain of the ground colour, set with light long thorns. The species resembles *continua*, but it is larger, more pink, and with more distinct white transverse lines. In the Coll. HOPP there is a ♂ labelled: Texas. The statement that *alinda* occurs in Texas may refer to *coinopus* which is often confounded with *alinda*.
- continua*. **H. continua** Wkr. (114 e) is a smaller lilac grey species with a very faint reddish tint, a thick faded discal spot and hardly recognizable transverse lines; a discal spot is also on the hindwing, but no distinct lines. Mexico?
- euphemia*. **H. euphemia** Dyar (114 e, f). Pinkish-brown, palpi and legs rosy red. Apex of forewing not falciform, marked as *alinda*, but more fadedly and indistinctly. Abdomen of ♂ with ochreous hair and blackish bands, ♀ laterally and at the end with golden ochreous hair. Mexico (Misantla).
- cressida*. **H. cressida** Dyar (114 f) is likewise very closely allied to *alinda*, but the ♀ is black-haired on the sides and at the end of the abdomen. Somewhat smaller than *alinda*, forewing less falcate, the markings less distinct. This species and the preceding one are so very similar in the ♂ that they are hardly separable, but the ♀♀ are well discernible by the abdominal hair. Mexico.
- ebalus*. **H. ebalus** Gr., according to the figure, is a small pink male which is not to be identified: perhaps the ♂ of *obsoleta* Stoll?

12. Genus: **Lonomia** Wkr.

We insert this genus here owing to certain resemblances in the structure of the body to *Hylesia*. Proboscis absent or only a feeble thread; palpi relatively well developed, ascending, but not projecting beyond the frons, with a very short last joint. Body slim, wings broad, in the ♂ sometimes slightly falciform, very much like a Geometrid. Forewing with the same neuration as in *Dirphia*, on the hindwing the cross-vein is more oblique, the lower cell-end is produced, 3 and 4 near together; the origins of 5, 6 and 7 are likewise close

together. ♂ antennae usually shorter than the thorax, rather feeble, bipectinate, in the ♀ plain. The species are distinguished by an uncommon variability, especially in the males.

Type: *L. achelous* Cr.

L. achelous Cr. (= *obliqua* Wkr., ♂ *albigutta* Wkr.) (119 c) ♂ ochreous or reddish ochreous, strewn *achelous*, with a scarcely darker colour, smoothly scaled, with a hardly traceable somewhat greyer antemedian line forming distally convex bows in and below the cell; in the upper and lower cell-angles one white spot each; the purple brown or black almost straight postmedian line from shortly before the apex to the centre of the inner margin, inwardly bordered with whitish or grey, occasionally before it yet a grey parallel line; subterminal faint grey irregular shading, projecting between 2 and 4. Hindwing with a straight grey median line and a hardly traceable subterminal shadow. Beneath lighter, more coarsely speckled, with 2 small blackish, light-ringed discal spots on each wing; hindwing especially costally spotted grey with a large apical spot and a whitish undulate subterminal line. ♀ more thinly scaled, lighter and more greyish-brown, in the marginal area somewhat darker, with a distinct subterminal shading. Widely distributed: Brazil, Bolivia, Antilles. -- **vulpina** f. n. (119 c) is the name of a particularly large, reddish ochreous form, from Novo Friburgo, with a *vulpina*, strong black double line filled with lead-grey, and intense blackish subterminal shading. Type in the Berlin Museum. — **carnica** Schs. is very similar, but of a flesh-coloured or carmine pink ground colour and only faint *carnica*, subterminal shading; the oblique line is here also double and filled with grey, the upper one of the two discal spots blackish, only the lower one white. Under surface light brownish-red with a broad marginal brightening, hindwing with a black, white-edged discal spot. Petropolis; Sa. Catharina.

L. cynira Cr. (= *electra* Drc.) (119 b, c) has somewhat broad and obtuse wings coarsely strewn with *cynira*, blackish, otherwise very similar and just as variable, the two white discal spots mostly connected by a curved or angular blackish streak or rarely situate in an oval blackish spot. The ♀ is more grey or reddish-brown, with a more distinct light dentate-undulate subterminal line. --- **concordia** Drc. are somewhat deeper orange males *concordia*, with a more distinct subterminal shading. Mexico to Guiana; probably only the northern form of *achelous*.

L. submacula Wkr. (= *apicalis* Wkr., *falcata* Wkr.) (119 d) differs in the ♂ in the higher and shorter *submacula*, shape of the wings. Apex of forewing slightly falcate. Distal margin somewhat concave, hindwing with a slight angle below the centre. Light reddish-brown, strewn darker, with 2 blackish transverse lines, the anterior one forming 2 bows, the posterior line from the apex to the distal third of the inner margin; discal spot oval, blackish with one or two faint whitish centres above and beneath; behind the feeble subterminal shading some small light yellowish spots; hindwing the same, the yellowish small subterminal spots very prominent. ♀ in the marginal area on both wings darkened brown, otherwise the same. Venezuela to Peru and Brazil.

L. diabolus (Maass. i. l.) sp. n. (119 d). Shape of wings the most similar to *submacula* and almost *diabolus*, similar to that of small *Copaxa*. Monotonously blackish-brown, strewn a little with lead colour, without the antemedian line, only in the lower cell angle a small white spot; the oblique line of the same course as in *submacula*, slightly darker, inwards bordered with lead colour; subterminal shading hardly marked. Beneath lighter and more brownish with a slightly darker oblique stripe and small, lighter-ringed discal spots. According to 2 ♂♂ from Cayenne, type in the Berlin Museum; a third ♂, likewise from Cayenne, is smaller and more reddish-brown; another ♂ from Teffé (Amazons), in the Senckenberg Museum, is also somewhat browner and has a very distinct straight antemedian line on the hindwing. Apex of forewing somewhat less falcate.

L. abnegata Wkr. has unfortunately remained unknown to me.

abnegata.

13. Genus: **Periga** Wkr.

Scarcely different from *Lonomia*: apex of forewing somewhat more pointed and distal margin straighter, anterior angle of hindwing somewhat angular. Palpi and antennae somewhat longer. On the hindwing 6 and 7 rise still nearer together than in *Lonomia*. Only 2 species:

Type: *P. circumstans* Wkr.

P. circumstans Wkr. (= *eluacina* Drc.) (119 d) is just as variable as the *Lonomia* species. ♂ straw- *circum-* coloured yellowish, orange, brick-red or brown, more or less strewn with blackish, with blackish transverse *stans*, lines, the anterior one undulate or only feebly bent, the posterior one straight, in the darker forms inwards bordered with a lighter colour; behind it an undulate subterminal line; at the cell end 2 blackish, often white-pupilled small spots which are mostly connected by a curved streak. Hindwing with a curved antemedian line, a stronger straight median line, and a dentate-undulate subterminal line. ♀ more thinly scaled and of a light ash-grey colour. Panama to Brazil.

oculata.

P. oculata Schs. is light orange with a fine brown antemedian line and a large grey spot at the cell end, surrounded by black and centred black; postmedian line whitish, slightly undulate and bordered somewhat greyish-brown from the apex to the distal third of the inner margin, distally shaded with orange; some dark subterminal lunulae. Hindwing with traces of a distal line, and a subterminal line which is dentate between 4 and 2. Expanse of wings: 40 mm. Minas, Brazil.

14. Genus: **Dirphia** Hbn.

Since KIRBY'S Catalogue few authors have hitherto discussed the classification of the genera *Dirphia* Hbn., *Phricodia* Hbn., *Ormiscoles* and *Catocephala* Blch. and *Plateia* Hbn., which is a sheer impossibility, for on superficially examining the species jumbled up there, it will be clear that on the one hand many species cannot remain together, on the other hand all the 5 genera contain species that belong into one genus. All the attempts of PACKARD, GROTE, and LYAR are neither satisfactory, because they comprised a much too small circle of species. Considering this fact, we have been forced to abandon the principle of our work, i. e. only to supply a classification of the lepidoptera hitherto known, and to try to arrange the species as well as possible according to the differences in the neurulation, as HAMPSON did, and it was found, in fact, that in this way a very suitable order could be attained. However, it must be considered that the arrangement of veins may sometimes also vary within the species even to a great extent. Thus I discovered, for instance, among a large series of *D. mexicana* Bouv. all kinds of variations: forewing 6 and 7 stalked, from the same base or separated, hindwing 6 and 7 the same, in one case even together with 5 from the same base; the same is the case in the forms of *avia*. The type, however, being assumed as the fundamental species always predominates by far.

Before characterizing the genus *Dirphia* in the following lines, we supply here an analytical table of our subdivisions. We must of course leave it to future authors to keep up or to alter this provisional and rough sifting in revising the insects in question here. It may be that the examination of the genitals will provide better results than those yielded today.

Dirphia (+ *Ormiscoles*, *Catocephala*, *Phricodia*, *Plateia*) sensu latissimo.

A. Forewing veins 6 and 7 not stalked.

a. Forewing veins 6 and 7 from the same base.

a¹ Hindwing veins 5 and 6 separated; ♀ without anal tuft and lateral wool.

a² Hindwing veins 6 and 7 separated

Dirphia Hbn.

b² Hindwing veins 6 and 7 from the same base or on a short stalk.

a³ smaller species, distal margin of forewing slightly convex

Catocephala Blch.

b³ larger species, distal margin of forewing slightly concave

Ormiscoles Blch.

b¹ Hindwing veins 5 and 6 mostly from the same base, ♀ with anal tuft and lateral wool *Hidripa* nov.

b. Forewing veins 6 and 7 separated.

a¹ Hindwing veins 5 and 6 from the same base

Dihirpa nov.

b¹ Hindwing veins 5 and 6 separated

Phricodia Hbn.

B. Forewing veins 6 and 7 stalked.

a. Hindwing veins 6 and 7 not stalked.

a¹ Hindwing veins 5 and 6 separated

Phidira nov.

b¹ Hindwing veins 5 and 6 stalked

Mesoleuca Wkr.

b. Hindwing veins 6 and 7 stalked.

a¹ Anterior tibia with a long horny sting

Kentroleuca nov.

b¹ Anterior tibia without a horny sting

Hirpida nov.

The forms which accordingly belong to the genus *Dirphia* are partly still very heterogeneous and will probably have to be subdivided later on. They are mostly very large lepidoptera, especially the ♀♀ are large, stout insects, most variably coloured and marked; according to the latter differences various groups of species can be assorted. Proboscis absent, the hairy palpi are very well developed, but do not project beyond the frons. Antennae of ♂♂ strongly pectinated, in the ♀♀ serrate and ciliated. Abdomen mostly short and rarely projecting beyond the hindwing. Legs short and stout, tibiae and femora covered with a dense hairy fur, hind tibiae only with one pair of short terminal spurs. Wings rather broad. As to the neurulation we refer to the table above.

Type: *D. tarquinia* Cr.

I. *tarquinia*-group.

D. *tarquinia* *Cr.* (= *acidalia* *Hbn.*, *tarpeius* *Hbn.*) (115 a) is a most variable and sexually most dimor- *tarquinia*.
phous species, at least in the male. The latter on its brown ground intensely white-haired and scaled, so that only an oblique basal area, a more or less large discal area enclosing a fine white Y-spot, and a subterminal notched band remain brownish-black. Hindwing basally and in the disc rusty brown with a black oblong discal spot, postmedianly more greyish-brown, turning whitish at the margin. Abdomen rusty yellow with black rings. The ♀ is blackish-brown, basally with a pinkish grey trapezoid spot, a long creamy white discal Y and an almost straight, only feebly undulate subterminal line behind which the marginal area is dusted with greyish white. Hindwing reddish brown with a blackish discal spot. Guiana, Amazons. BOUVIER describes an extreme variation from Venezuela; the ♂ with a much lighter oblique basal band and a very light brown discal spot, the submarginal band is almost entirely absent; hindwing without any white marginal zone; the ♀ lacks the greyish-white basal area and the white border line; wings dorsally very light chestnut brown.

D. *multicolor* *Wlr.* (= *ramigera* *Fldr.*) (115 a, b) is likewise sexually most dimorphous; ♂ with a dark *multicolor*.
brown oblique basal band and inner marginal half of the median area, a very irregular basal spot and the harpoon-shaped discal Y whitish, the apex of the latter black, projecting far beyond the undulate postmedian line; costal-marginal portion of the median area, and distal margin light brown, behind the postmedian line more or less broad pinkish-white, veins 6 and 7 with a few thick black dots. Hindwing pinkish-brown, basally darker pink, with a black discal oval or spot and 2 brown transverse bands behind it. Abdomen black with narrow reddish-yellow rings. The ♀ looks very much like that of *tarquinia*, but it is at once discernible by the light costal-marginal part and the differently shaped, more pinkish-white basal spot. Hindwing basally intensely dark pink, abdomen with much narrower reddish-yellow rings. Brazil. -- ***brasiliensis*** *Bouv.*, described *brasiliensis*.
according to a very large ♀ with an expanse of 135 mm, from Brazil, probably belongs to this place here; according to the description there seems to be only the difference that the discal Y does not extend to the subterminal line.

D. *horcana* *Schs.* (115 b) is much smaller, basal area with creamy white scales, produced in long dents *horcana*.
to the centre of the costal margin and of the inner margin, and brownish before the distinct border line, striped brown on the costal marginal veins; median area brownish-black with a narrow fine discal Y, distally defined by a straight postmedian line which is distally narrowly bordered with brown, traversed by creamy white veins; marginal area likewise creamy white, dusted with brownish, with a notched subterminal line forming dark brown notched spots between 2 and 3 and below the costal margin. Hindwing bright rusty yellow, at the margin greyish-white, with 2 greyish-brownish subterminal arcuate lines. In the larger ♀ the basal and marginal areas are pinkish-brown, the creamy white discal Y-spot reaches in the type ***brevifurca*** *Strd.* neither the ante- *brevifurca*.
median nor postmedian line, whereas in another specimen it reaches both. Costa Rica, Ecuador, and Colombia. In a male specimen from Villavicencio the blackish-brown median area is very narrow, the light basal spot extends at the costal margin with its apex beyond the postmedian line, the hindwing is intensely dusted with greyish-brown; it is probably only an individual variation.

D. *horca* *Dogn.* (115 c) is very similar to *horcana*, but the light basal spot does not form any distal *horca*.
notch at the costal margin, but bends subcostally still farther basad; subterminal line distally very slightly concave; the discal Y is much thicker, particularly the cross vein branch which contains an ochreous central streak. Hindwing redder, otherwise marked the same. The ♀ is similar to that of *horcana*. Ecuador; Venezuela: 1 ♂ c Coll. BANG-HAAS is labelled "Mexico"; South-Western Colombia (Putumayo).

D. *subhorca* *Dogn.* is exactly like *horca*, but the brownish-black median area is equally broad at the *subhorca*.
costal and inner margins, the hindwing exhibits a small black discal spot, and close behind it a postmedian line, both being absent in *horca*. Expanse of wings: 73 mm. Paramba (Ecuador), described according to a ♂.

D. *aculea* *Vuill.* (115 c) ♂ light pinkish-brown with a narrow brownish-black median area not reaching *aculea*.
to the inner margin and containing a fine creamy white Y, and traces of a mottled subterminal line which is only more distinct between 2 and 3; marginal area slightly darker. Hindwing pinkish-brown with a small darker discal spot and a reddish-brown postmedian line. The ♀ is very similar to that of *tarquinia*, but much smaller, with more pointed wings, basal and marginal areas pinkish-brown, basal area much more extensive; the discal Y does not reach to the postmedian line, its upper branch bears a fine brownish-black central streak. Amazons: Eastern Colombia (Upper Rio Negro).

D. *lombardi* *Bouv.* (115 c) is a smaller species, very similar to the following species and perhaps only *lombardi*.
a form of it; the oblique pinkish-grey basal area has distally a convex border, the dark brown median area is at the costal margin twice as broad as at the inner margin, the Y similar as in the preceding species, the upper branch centred brownish-black. Marginal area proximad pinkish-white, distally brownish with a notched subterminal line which begins very dark and intense at the costal margin, so that a light oblique streak parts the apex, and vanishes more or less in the centre. Hindwing very thinly scaled greyish-brown with a fine discal streak and a slightly darker postmedian line. Abdomen black, dotted white, at the anus reddish-yellow. Parana; Minas (Southern Brazil).

- della.* **D. delta** Foett. (= ♂ aphrodite Schs.) (115 d) is very similar to *lombardi*, the median area is narrower, the light basal portion outside irregularly bordered, the subterminal line is absent except a triangular dark costal-marginal spot, the discal Y almost entirely lacks the proximal branch, and the upper one ends more rounded. Hindwing of ♀ without the discal spot and postmedian line; in the ♂ they are present. South-Eastern Brazil.
- oridocea.* **D. oridocea** Schs. (115 d). Forewing with a dark oblique basal inner marginal area, the light pinkish-grey basal spot therefore ends pointedly below; in the dark brown median area with a creamy longitudinal spot on the median vein, and at the cell-end a large irregular spot outside with a long appendage ending taperingly and cutting the pinkish-brown postmedian line, the spot itself filled with a brown linear marking; occasionally there are small white dots above and below the appendage which may also be separated from the discal spot itself; marginal area as in *pulchricornis*. The ♀ is much lighter brown. Peru; Bolivia; Brazil (Espiritu Santo).
- tresignata.* **D. trisignata** Fldr. (= *irregularis* Foett.) (115 d) is somewhat similar to *oridocea*, darker brown, the pink basal area at the costal margin longer than at the inner margin; at the cell-end a glossy silvery creamy-white renimacular spot centrally marked brown, with 1 or 2 dots behind it; subterminal area scarcely lighter, the subterminal line very indistinct. Hindwing brown, basally pink. Brazil. Larva, according to a figure by F. SCHADE-VILLARICA, above yellowish-green, beneath more bluish-green with a pink lateral stripe, scanty fir-tree-like short spines and on the 2nd and 3rd rings 2 much longer straight porrect spines each, on the last ring 2 turned hindward.
- pulchricornis.* **D. pulchricornis** Wkr. (= *pomona* Fldr.) (116 a) is very similar to *trisignata*, of a duller colouring, the basal spot does not end so pointedly at the inner margin, the median area is bordered more in a parallel way, behind the discal spot the dots are absent; hindwing lighter pinkish-brown with a distinct lighter submarginal line. Mexico to Venezuela.
- schreiteri.* **D. schreiteri** Schs. (116 a). Palpi, chest and legs red, head olive brown; thorax and abdomen black, basal segment red, the following ring-indentations without scales, anus orange, ventrum whitish, with olive hair, laterally spotted and dotted white. Forewing with a blackish-brown basal stripe, behind it a large white triangular spot; median area sandy brown, slightly strewn, at the costal and inner margins whitish; cell end blackish-brown, with a short white streak on the median vein and a large white reniform spot at the end between vein 3 and the subcosta, centred yellow, strewn with black scales, and with a white branch on vein 5; marginal third somewhat lighter than the median area with a whitish postmedian spot from the costal margin to 6, and a white line between 3 and the inner margin; a broad subterminal whitish band incurved from the costal margin to 5, excurved to the margin on 3 and at the anal angle. Hindwing scantily scaled, basal and marginal areas suffused with sandy brownish, the marginal area strewn with white, at the cross-vein a spot bordered with white, and red hair at the base of the inner margin. Tucuman, Argentina.
- spumosa.* **D. spumosa** Vuillot was not before me. Forewing brownish ashy-grey, spots and markings yellowish-white; at the base a hook-shaped spot extending along the costal margin, then turning narrowed back to the inner margin, and cutting a long white spot at the lower edge of the cell; at the cell end a large triangular white spot; a subterminal whitish brightening from the apex, very sinuate, then narrowed to the inner margin, traversed by brown veins; hindwing light chocolate, scantily scaled, at the inner margin with light red hair. Metathorax and patagia with long grey hair; thorax brown, posteriorly garnet-red. Abdomen above brown, beneath red-brown, on each side 2 white dots on each ring. Expanse of wings: 80 mm. Brazil, Sa. Catharina.
- flora.* **D. flora** Schs. is near *pulchricornis*, more pinkish brown, the large irregular yellowish-white discal spot is erect, not oblique as in *pulchricornis*, it exhibits in the centre an irregular brown spot parted by a white line: distal area lighter brown with a grey subterminal shadow and behind it pink shading before the marginal area which is brown between the apex and vein 2. Hindwing brownish, at the margin narrowly pink. Expanse of wings: ♂ 69, ♀ 89 mm. Costa Rica.
- ayuruoca.* **D. ayuruoca** Foett. (116 a), described according to a ♀, is of a lighter yellowish-brown ground colour, the oblique dark basal inner marginal spot is absent, the basal spot is greyish-white and below the cell it shows a long narrow appendage; behind the discal renimacular spot there are single yellowish-white dots and a longitudinal streak on vein 5; postmedian line parallel to the margin and to the subterminal line behind it, the latter projects, dusted with greyish-white, towards the margin between 2 and 4. Hindwing lighter and greyer with a feeble discal spot and a straight subterminal line. Abdomen black, with narrow reddish-yellow rings, with rusty brown anal hair. Southern Brazil.
- epiolina.* **D. epiolina** Fldr. (116 a) connects *ayuruoca* with *picturata*. Forewing on the olive yellow ground densely strewn with black hair-scales, marking very similar to that of *picturata*, basal spot not reddish but light yellowish-grey, the discal macula much larger and more complicated, all the veins of the median area abundantly spotted yellowish-white; the marginal markings almost as in *picturata*, but more yellowish-white, and before them with a bluish subterminal band. Hindwing more smoke-brown, at the inner margin with cinnamon-brown hair; abdomen as in *picturata*. A most variable species, from Venezuela to Southern Brazil (Sa. Catharina; Casa Branca).

D. picturata Schs. (116 a) is the most similar to *oridocea*, of a much darker brown ground colour, the *picturata*, very irregularly shaped basal area darker pink, the yellowish-white discal spot with generally 3 dots behind it on vein 5 and often a strigiform spot below the median vein before it with a silvery gloss; in the lighter pinkish-brown subterminal area the very distinct subterminal line broken up into dark brown spots. Hindwing basally pinkish carmine with a small pink-ringed discal spot and 2 strong dark arcuate lines behind it. Rio de Janeiro.

II. rosea-group (*Rhodormiscodes* Pack.).

D. rosea Drc. (114 g). In the blackish-brown thorax long stiff white hairs are intermixed; abdomen *rosea*, orange, above with black rings, a black lateral line, below it white with black spots. Forewing basally below the cell with a large blackish-brown spot, above it pinkish-whitish, striped brownish; at the cell end a distally mostly three-pronged, white-edged discal spot; the oblique black postmedian line from 6 to the inner margin, inside bordered with pinkish-white, outside the broad brown subterminal band distally bordered with pinkish-white, subapically at the costal margin a large blackish-brown trapezoid or triangular spot. Hindwing pinkish blackish, basally pinkish carmine with a large hazy blackish discal spot and 2 bands behind it. Fringe at the ends of the veins speckled lighter. Mexico; a most variable species.

D. ninfa Schs. is extremely similar; head and palpi more orange, the abdomen lacks the black lateral *ninfa*, line. On the forewing the upper edge of the blackish-brown basal spot is somewhat rounder, the distal one on the submedian fold interrupted inwards; before and below the discal streak one grey spot each. Expanse of wings: 52 mm. Described according to a ♂ from Jalapa (Mexico).

D. latemedia Drc. (114 g) is similar, larger, browner, the blackish-brown discal spot considerably larger, *latemedia*, basally produced on the median vein; the transverse lines are composed of black internerval lunae, scaled orange on the averted sides, then bordered with whitish; terminal area as in *rosea*. Hindwing brown, without any pink, the strong postmedian line is distally broadly edged with whitish. Abdomen beneath brownish-black. Described from Ecuador, also from the Amazons, Bolivia, and Peru.

D. tusina Schs. differs from *rosea* in the deep pink ventral side; thorax and abdomen above as in *rosea*, *tusina*, separated from the likewise similar *latemedia* by the more pinkish-brown wings, especially in the median area of the forewing which shows a black dot at the base of the costal margin, the transverse lines as in *latemedia* intensely scaled orange; the apical costal marginal spot is small. Hindwing as far as the postmedian line purple red, behind it lighter; the large round black discal spot touches the thick postmedian line. Expanse of wings: 61 mm. Tuis, Costa Rica.

D. placida Schs. (114 h) is likewise similar, but the abdomen is orange beneath, the white tarsi with *placida*, black rings. Forewing brownish grey, the basal inner marginal spot above straightly cut off, outside bordered by 3 black crescentiform bows; the crescentiform postmedian line is straight between 2 and the inner margin, the apical spot triangular, bordered with white, the large brown discal spot inwards bordered with black. Hindwing brownish, at the inner margin darker, otherwise as in *latemedia* from which the species chiefly differs in the abdomen being orange beneath. French Guiana.

D. lulesa Schs. (114 h) is likewise allied to *latemedia*, but the ground colour is more olive grey, inter- *lulesa*, mixed with single red-brown hairs, the black crescents of the transverse lines bordered by dark yellow scales; the brown discal spot is bordered with black and dark yellow; subterminal line as in the other species, the subapical spot is a triangular shadow. Hindwing whitish with a brown marginal band and subterminal line, the latter black towards the inner margin; costal margin and disc as far as the postmedian line flesh-coloured pink, base, cell and inner margin with long pink hairs, at the cell end with a large round black ocellus centred with light blue; postmedian line thick, black, incurved below the costal margin; marginal veins dark yellow. Argentina (Lules).

III. sabina-group (*Molippa* Wkr.).

D. sabina Wkr. (114 h). This group differs from the preceding one merely in the somewhat more *sabina*, produced apex of the ♂ forewing and in the thoracal hair being intermixed with stiff black oar-shaped hairs. A most variable and common species of a wide range. Forewing yellowish-white, more or less densely strewn and mixed with ochreous, brown and grey. Marking exactly that of the *rosea*-group, i. e. the base of the inner margin with a large somewhat darker spot, transverse lines as in *latemedia* composed of lunulae, double; discal spot of a most variable shape and size; the dark apical costal marginal spot outside bidentate. Hindwing with a most variable discal spot, 2 dentate more or less black lines behind it, and orange veins in the marginal area. Type from Brazil. — **nibasa** Maass. (114 h) shows a very clear marking, a very dark basal inner-marginal spot *nibasa*, of the forewing, and very distinct, narrow, deep black bands on the hindwing. Type from Mexico. — **simillima** *simillima*, Jones (122 e) are specimens in which the black bands of the hindwing are said to bend down analwards, whereas in *sabina* they end straight. According to JONES' observations, *simillima* is yielded from yellow larvae irrorated

with black, remaining during the day on the food-plant (Eucalyptus, Mimosa etc.), *sabina* from dark grey larvae hiding in the daytime on the trunk of the same food-plants. The problem *sabina-simillima* must yet be carefully investigated. JONES considers *sabina* to be the species with a male uncus split like a Y, *simillima* that in which the spiny uncus is somewhat stalked patelliform. BOUVIER, on examining the species in the Paris Museum, found *simillima* to be the form occurring to the north as far as Mexico, *sabina* to be the Brazilian form, which fact I can substantiate according to about 50 specimens at hand. All the specimens from Mexico, Guatemala, Venezuela, and Colombia have an unsplit uncus, thus to be placed to *simillima*, whilst all the Brazilian specimens before me are *sabina*. JONES on the contrary, however, found in Brazil the larvae of both forms at the same time on the same food-plant. The neural differences in both forms or species stated by BOUVIER I cannot confirm according to the great number of specimens before me; I have never seen such an oblique course of the discocellular as it is sketched by the said author, in all the specimens seen the cross-vein stands almost vertical on the upper and lower cell-margins. Moreover, it is very easy to state where the ♂ belongs to, since by slightly brushing off the anal hair the very characteristic uncus is at once visible: as to the ♀, it seems that all attempts of identification have been in vain.

basina. **D. basina** Maass. is similar, but smaller, darker, on the forewing much more mixed with blackish-grey, particularly in the marginal area ashy grey. Hindwing slightly hued with salmon-pink. Abdomen orange, with narrow black rings. From Venezuela (La Guayra).

binasa. **D. binasa** Schs. (114 h) is very similar to *basina*, at once discernible by the abdomen being quite black above; forewing somewhat lighter, in the median area pinkish-white, the anterior transverse line irregularly notched brown, double, the posterior line deeper black; the light ashy grey subterminal band is traversed by orange veins, the narrow marginal area behind the white undulate line is orange brown. Hindwing salmon-pink, the postmedian line which touches the black discal spot with a jet-black central line is incurved below the costal margin, behind it there is a broad black subterminal band; the pink marginal area between the orange veins is densely strewn with black. Argentina (Tucuman); also from Rio de Janeiro.

basinoides. **D. basinoides** Bouv. is allied to *sabina* and *basina*. Body the same, on the rusty red abdomen also with orange spatulate hairs. Forewing in the basal costal marginal half as far as the median vein and the postmedian line grey, the large yellowish grey dark cellular spot somewhat rectangular, bordered with whitish; transverse lines as in *sabina*, olive grey, bordered with white; subterminal area blackish grey, the darkest proximad; the space below the cell olive grey like the marginal area behind the white irregular submarginal line; veins in the distal two thirds orange. Hindwing unicoloured yellowish-white at the margin olive grey, before it with a blackish subterminal band, traversed by the orange veins; at the cell end only a feeble blackish streak. Expanse of wings: 64 mm. Brazil, described according to a single ♂.

IV. speciosa-group.

cutteri. **D. cutteri** Schs. Head and mesothorax reddish-yellow with a black spot on the collar, metathorax dark pink, abdomen as in the preceding species. Forewing reddish-brown, suffused with pink, with black veins, at the cell end a thick antimony yellow spot with a whitish dent along vein 4 distally as far as behind the broad blackish straight postmedian line; fringe at the distal and inner margins pink. Hindwing pink, with black veins with broad blackish postmedian and subterminal shadows. Ecuador.

upanona. **D. upanona** sp. n. (116 b) is very similar to *cutteri* and perhaps a form of it. Head and thorax black, collar and patagia with single yellow hairs, abdomen quite black with reddish ochreous anal hair. Forewing coffee-brown, with black veins, the discal spot quite yellow, fringe claret-coloured; the blackish postmedian shadow is scarcely visible. Hindwing quite sooty black, without markings, with fine black veins which are thickened into small triangles before the claret-coloured fringe. Type: 1 ♂ from Normandia, Rio Upano, Ecuador in the Coll. BANG-HAAS.

radama. **D. radama** Drc. (116 b) is chrome-yellow, in the inner marginal portion of the forewing dusted with a somewhat deeper or brownish colour, with fine black veins, a white, above black-striped Y-spot at the cell end, cutting a blackish shadowy line. Hindwing likewise yellow with a blackish postmedian shadow; fringe speckled black and white. Abdomen black, with white rings and an ochreous anal tuft. Ecuador.

mota. **D. mota** Drc. (116 b). Head and thorax rusty yellow, wings pink, with yellow veins; forewing in the median area and at the inner margin slightly mixed with a rusty yellow colour; cellular spot as in *radama*, but the white discal portion broader and rounder. Hindwing at the inner margin with rusty yellow hair, with a small whitish discal spot. W. Colombia, San Antonio; before me from the Agnaca Valley.

pachona. **D. pachona** sp. n. (116 b) is similar to *mota*, larger, forewing and hindwing quite fox-coloured, with fine yellow veins, with the same blackish postmedian shadow; discal spot of forewing as in *mota*, but the middle part and the upper branch of the Y filled quite black, with an extremely fine yellow vein-line running through. Body as in *mota*. Type: 1 ♂ from Pacho (Eastern Colombia) (FASSL leg.) c Coll. BANG-HAAS.

D. speciosa Cr. (= quadricolor Wkr.) (116 c) is an uncommonly variable species. Head and thorax *speciosa*, varying between rusty yellow and brown, abdomen black with white rings and a rusty yellow anal tuft. Forewing in the type pinkish carmine, with black veins, a more or less distinct blackish postmedian nebulous band and a long white, interruptedly black-filled Y-spot at the cell-end, below which there is often another white sagittiform streak on 3. Colouring variable; another form: — **brunnea** f. n. (116 c) exhibits instead of the pink colour a *brunnea*, light coffee-brown colour, at the margins often more or less hued with pink, but apparently it flies together with the typical form without any transitions. Costa Rica to Ecuador, Peru and Bolivia, also in Trinidad. — **flavoscripta** Dogn., described according to a ♂ from Ecuador with an expanse of 75 mm, probably belongs to *flavoscripta*, this species, too. Forewing chestnut-brown, at the costal margin strewn with yellow, the continuation of the Y, situate on the cross-vein in the direction to the costal margin, is yellow, the other parts as in the type black and white; abdomen above black, without the white rings, beneath brown. The Berlin Museum owns a chestnut-brown ♀ from Chuchuras, Peru, which likewise shows an entirely black abdomen without white rings, but an entirely white Y as in the type. In a carmine ♀ from Rio Pachitea, Porto Alegre, only the first ring is broadly edged with white, all the others are quite black. — **avenata** f. n. (116 c) I denominate a form from Chiriqui, *avenata*, Panama, in which the veins of both wings are of the ground-colour, not prominently black. Ground-colour rusty brown, with a rosy-red hue at all the margins. Hindwing with a thick white discal streak. Type in the Berlin Museum. It may be a distinct species.

D. consaepta sp. n. (116 c) is very similar to the brown forms of *speciosa*, but at once discernible by *consaepta*, white fringes speckled black at the ends of the veins. The brown ground-colour shows a more olive yellowish tint; the blackish postmedian nebulous stripe is situate nearer to the margin and mostly more prominent; the discal Y is creamy white, much thicker and proximally more deeply and acute-angularly notched, the part resting on the end of the median vein and vein 3 is very broad. Hindwing in the proximal inner-marginal half with somewhat lighter reddish hair, the nebulous stripe broad and distinct, beneath with a white costal-marginal stripe and white dusting in the disc and behind the postmedian stripe. Body as in *speciosa*. Types: 1 ♂♀ from Icononzo near Pandi (Colombia) in the Coll. HOPP, Charlottenburg; 1 ♂ from Chaco, La Paz (Bolivia) in the Coll. BANG-HAAS.

D. flavodiscata Dogn. (116 d). Forewing olive yellowish, in the interspaces strewn with blackish hair-*flavodiscata*, scales which are intensified in the first and second thirds to nebulous transverse bands, the posterior band somewhat concave towards the margin between veins 2 and 3; veins black, at the margin thickened into small triangles; at the cell-end a large yellow spot. Hindwing the same, but without the yellow cellular spot. Abdomen with yellow and black rings, basally more intensely black, the anus red. Colombia, Bolivia.

D. erythropus Maass. (116 d) is similar; on the forewing the interior transverse band is situate behind, *erythropus*, not before, the white (not yellow) angular spot, the exterior band is nearer to the margin and outside broadly bordered with white. Legs rosy-red. Ecuador.

D. zeta Berg is distinguished by long red-brown antennae; thorax blackish-brown mixed with yellow, *zeta*, abdomen blackish-brown with rusty yellow segmental margins and a yellow anus. Forewing reddish-yellow, densely striated and strewn with black or blackish-brown, the whole cell filled with black, outside and below marked with a black, white-edged Z. Hindwing likewise Isabel-coloured, only at the margin striated blackish-brown, at the cell-end with a large round black macula; fringes in both wings light brownish. Expanse of wings: 105 mm. According to a ♂ from Buenos Aires (Sierra Chica), Argentina. The species having remained unknown to me, I can only insert it here provisionally; it may belong rather to *Ithomisa* or *Eudyarina*.

D. laverna Drc. probably belongs to the same group. As I could not examine the species myself, I cannot *laverna*, tell whether it belongs to *Dihirpa* next to *litura* owing to the white basal cellular spot. Forewing semidia-phanous black, densely strewn with yellow, with black veins, a yellow longitudinal spot behind the base of the cell, and a yellow angular spot at the cell-end; the white fringe is speckled with black on the ends of the veins. Costal margin of hindwing beneath yellow. The black body is covered with long yellow hair, the collar yellow, abdomen with black and yellow segments, anus and legs red. Antennae black. Ecuador. — **albomaculata** *albomaculata*, Dogn. is somewhat smaller, blacker, and more densely scaled; the spots in the cell are of a pure white, not yellow, the discal spot divided into two parts or almost divided, also on the hindwing an intense discal spot. Legs and anus light pink. Loja (Ecuador).

D. monticola Zerny (118 e) is rather isolated, but surely no *Heliconisa*. Forewing varying between *monticola*, ochreous and olive brown, with fine blackish veins; a white postmedian arched line parallel to the margin bends inwards above the inner-marginal vein and extends to the base of the costal margin, without reaching it: at the cell-end a whitish small, brown-centred oval spot. Hindwing darkend towards the margin with a rather inconspicuous lighter submarginal line. Thorax darker than forewing, abdomen above black, laterally and at the anus rusty red. The ♀ is darker. Larva black, with black spines and a red-brown head, it lives on *Rapanea flocculosa*; the pupa lies on the ground, without a web, amidst dry grass in a hollow made by the larva. The ♂ imago flies in the afternoon, it also comes to the lantern at night. South Brazil.

V. *menander*-group.

- radiata*. **D. radiata** Dogn. (116 d). Antennae ochreous, body dark brown, thorax with a white transverse stripe, abdomen with ochreous-red bands. Forewing olive brown, with white veins, with a brown discal streak which is bordered with white on both sides, and 2 double transverse lines, the anterior one straight, the posterior one somewhat undulated, interrupted by white and brown strewn internerval streaks which terminate at the margin in long white lance-points; margin strewn with white; fringe speckled brown and white. Hindwing somewhat lighter olive brown with traces of a rounded postmedian line, white marginal strewing and white ends of the veins. French Guiana.
- dukinfieldi*. **D. dukinfieldi** Schs. (116 d) may not belong here, because the discocellular especially on the hindwing extends more obliquely and the lower cell-end is therefore more produced, as in the genus *Heliconisa*, to which the species, however, does not belong owing to the ♂, nor to *Hemileuca* as which it was described. Head and thorax blackish, with olive yellow hair, patagia of ♂ deep black. Abdomen above bright ochreous, ventrum yellowish-grey, sides deep black with small white spots. Forewing blackish-grey, veins orange, narrowly edged with light yellow; behind the cell with a white transverse line parallel to the margin; base of fringe narrowly orange, ends greyish-white. Hindwing the same, but duller, veins finer and more distinct, purely orange. Castro, Parana; Paraguay.
- amarilla*. **D. amarilla** Schs. (116 e). Head black, collar dark pink; thorax greyish-brown, the patagia covering almost the whole thorax are dull yellow; abdomen above black, base and anus pink, ventrum orange with black spots, sides pink with black transverse lines. Wings dull yellow, forewing with dark violettish-grey veins, similar stripes at the costal margin, in and below the cell; violet antemedian and postmedian transverse shadows, and at the cell-end a dark red spot. Veins of hindwing in the distal half dark violettish-grey, at the cell-end a pink spot. Costa Rica, Volcano of Turrialba.
- menander*. **D. menander** Drc. (116 e). Body rusty yellow, abdomen with black segments. Forewing brownish red, with a white, slightly S-curved postmedian transverse stripe not reaching the costal margin, ending in the centre of the inner margin and being edged with jet-black on both sides; the veins distally to it whitish, on both sides broadly shaded with grey, fringe white. Hindwing blackish-grey with a white median line and white fringe. Nicaragua and Panama. — **reducta** Her. & Hopp (116 e), a fine race from Western Colombia, differs in its brighter, more carmine ground-colour and the straight white median stripe which is only outside edged with black; the veins also in the hindwing of a broader and purer white, less shaded with grey. In the genital organs also somewhat different.
- carminata*. **D. carminata** Schs. is light brown on the head and ventral side, thorax, base of abdomen and anus like the forewing light red, abdomen black, with brownish bands. Forewing in the distal half with fine white veins, with an antemedian and a postmedian transverse line divided into 3 black spots each and on both sides bordered with white. Hindwing basally light brown with a large dark spot at the cell-end and a dark, distally whitish-edged median band; distal half blackish-brown, with fine white veins. Mexico (Jalapa). — **niepelti** f. n. (117 a), from West Colombia (Bella Vista), is a magnificent, much larger and deeper carmine form. Head and ventrum are here deep black like the white-ringed abdomen; between the white veins in the marginal area there are towards the apex white internerval triangles, the largest between 7 and the apex; the uppermost of the postmedian spots is divided into two parts. Base of hindwing and inner margins of both wings broadly haired rusty yellow, hindwing besides also in the basal half black, the black median band especially below the cell also proximally broadly bordered with white.
- zikani*. **D. zikani** Schs. (117 a) is a smaller species which is difficult to range. Head brown, thorax brownish-grey, behind with pinkish-white hair; abdomen above black with white segmental lines and a red anus, beneath greyish-brown. Forewing greyish-brown with blackish-brown transverse lines, the interior line vertical from the costal margin to the median vein, then turning to the inner margin, on both sides bordered with white, inside broader; at the cross-vein a black dot and a fine line excurved to vein 4; the black postmedian line is only inside bordered with white, from the costal margin to the centre of the inner margin; a whitish subterminal lunar line distally shaded with dark grey and vanishing between 4 and the apex. Hindwing greyish-brown, base of costal margin pink, with a fine dark discal line and a postmedian line from the costal margin to 4; fringe between the ends of the veins white. Passa Quatro, Minas, Brazil.

VI. *agis*-group.

- agis*. **D. agis** Cr. (117 a) is a large species, forewing light brownish-grey, the ground of the wing almost invariably with a slight rosy tint or pinkish-brown, with distinct dark brown veins; the anterior transverse line, feebly convex towards the margin, is black, proximally white and extends, as in all its allies, from the base of the costal margin behind the interior third of the inner margin; cross-vein almost straight, below the centre only slightly flawed inwards; posterior transverse line straight or feebly concave towards the margin, slightly widened at the costal margin, blackish-brown, inside white, the traversing veins here orange, it cuts vein 4 close at the lower cell-angle as far as $\frac{1}{4}$ at most of its length; the darker subterminal shadow recedes to the transverse line between 4 and 5, between 2 and 4 farther towards the margin than between 5 and 7. Hindwing mostly somewhat darker smoke-brown. Abdomen orange, with black rings. Brazil to Peru.

D. regia *sp. n.* (117 b) is very similar, perhaps only a form of it. Ground-colour rosy-red, behind the cell, below it between 2 and 3 and subterminally feebly covered with olive grey; transverse lines deep velvety black, proximad cut by snow-white not yellow, the smoke-brown veins only behind the line faintly tinted with rusty brown; anterior line quite straight, not extending to the inner margin, but below 1 curved upwards again, for a short distance parallel to the white border of the posterior line which is quite straight, cutting 4 close behind the cell. Hindwing brownish pink with a feeble whitish arcuate line in the centre, fringe white. Abdomen almost quite orange, the black rings in the ♂ only very narrow. Types: 1 ♂ from Western Colombia, Bellavista, in the Coll. NIEPELT, 1 much flown ♀ from the Chiriqui, Panama, in the Berlin Museum.

D. imperialis *sp. n.* (117 b) is of a bright orange on the thorax and forewing, with brown veins; transverse lines as in *regia* deep black, proximally white, before it again some black scales, the white portion black, the black portion traversed orange on the veins; course of the anterior line as in *agis*, posterior line likewise almost straight, cutting 4 as far as $\frac{1}{3}$ behind the base; subterminally darkened as in *regia*, between 2 and 4 not projecting farther towards the base than between 5 and 7. Hindwing bright crimson with a somewhat lighter arcuate stripe as in *regia*, fringe white. Abdomen orange with black rings. Type: 1 ♂ from Bellavista (Western Colombia) in the Coll. NIEPELT.

D. mexicana *Bouv.* (117 b) is similar to *agis*, more greyish-brown, mostly without a pink tint, all the veins, also the submedian fold orange; cross-vein mostly feebly concave; transverse lines similar as in *agis*, but often contiguous at the inner margin as in *regia*; basal area lighter than the ground; the posterior transverse line cuts vein 4 before or in its basal third; the subterminal darkening does not quite recede between 4 and 5 to the posterior transverse line. Hindwing scarcely darker than forewing. Mexico.

D. eumedidoides *Vuill.* (117 e) is smaller, ground-colour darker, more chestnut or greyish brown, in the type at hand the basal area is remarkably lighter, almost whitish, antemedian line very fine, blackish, proximally not bordered with white, with yellow spots on the median vein and vein 1; veins hardly darker than the ground, the cross-vein forming a flat angle, the sides of which are equally long; posterior transverse line slightly curved, expanded into a white triangle at the costal margin, very fine black, inside scantily bordered with white hair-scales, cut by yellow; it cuts 4 behind the basal quarter; subterminal line irregular, whitish, undulated, the area before it darker grey, behind it light reddish-brown. Hindwing like the marginal area of the forewing with a broad extinct postmedian nebulous band. Amazons, Colombia. Peru.

D. eumedide *Stoll* (117 c) is mostly darker than *agis*, without a pink tint, otherwise very similar, but the posterior transverse line feebly bent and cutting vein 4 in or behind the basal third. Panama, Ecuador, Guiana.

D. varia *Wkr.* (117 c) is likewise extremely similar; the cross-vein forms an angle the upper side of which is shorter, the lower one longer; before the discal spot angularly covering it the cell is lighter whitish almost to the base; transverse lines as in *eumedide*, the posterior one cuts vein 4 in less than $\frac{1}{3}$ from the base. Bolivia, Peru.

D. infuscata *Bouv.* (117 c) is dark smoke-brown, the transverse lines are broader white than black, the yellow-crossing veins are not very prominent; the cross-vein and discal spot form a basally slightly convex bow; the anterior transverse line forms a straight very oblique line running far distally; the posterior line cuts vein 4 in more than $\frac{1}{3}$, often in $\frac{1}{2}$ of its length. The black abdominal rings are very broad. Colombia, Ecuador.

D. peruvianus *Bouv.* (117 d) is very similar to *infuscata*; ground-colour dark smoky brown, sometimes with a violettish-pink tint, veins fine black, generally not very prominent; anterior transverse line as in *infuscata*, often twice cut by yellow, but the yellow may also be absent; on the posterior transverse line there are mostly only white vein-dots, but at the costal margin it is expanded into a white triangle. Abdomen above almost quite orange, only laterally with broad black segments with white spots. Peru, Ecuador.

D. pallida *Wkr.* (117 d) is creamy white on the wings, with yellow veins, the fine transverse lines blackish-brown, at the inner margin both are very near together; the cross-vein is an ochreous angular streak; the posterior transverse line cuts vein 4 within the proximal quarter. Thorax as forewing, abdomen above unicoloured orange, beneath creamy white, laterally with feeble traces of darker segmental margins. Antennae black. Colombia.

D. alba *Drc.* (103 A a) I only know from the photograph of the type which was kindly sent by Mr. TALBOT of the Hill Museum and which we figure; it seems to be allied to *pallida*. Head yellow, antennae black, anterior body grey, abdomen white, 2nd segment and anus yellow. Forewing white, with brown veins, with a curved brown line from the base of the costal margin to the centre of the inner margin, and a straight brown distal line; apex and 2 marginal thirds dusted with blackish-brown. Hindwing snow-white, costal and distal margins bordered with brown, fringe white. Under surface white, with black veins and apex of forewing. Eastern Ecuador, Alpayacu, Rio Pastazza, 3600 m.

D. aurora *Vuill.* (117 d). Body orange, also the abdomen only in the proximal half laterally somewhat black with white spots therein. Wings light ochreous or brick-coloured reddish, with yellow veins on the forewing, the oblique antemedian line rather inconspicuous; posterior line greyish-white, rather straight, inside very

finely, outside broadly edged with blackish-grey, on the outside the black colour on either side of the yellow veins is somewhat flown out towards the margin, so that a kind of denticulation may be produced; at the cell-end a tiny black dot may be present or also absent. Hindwing with a hardly noticeable trace of a light median line. In the ♀ the postmedian line may be reduced to an equally broad straight grey band crossed by the yellow veins. Antennae black. Colombia; Guiana.

medinensis.

D. medinensis *sp. n.* (117 A a). Anterior body light ochreous, abdomen of a brighter orange, laterally black with white spots, tarsi and antennae black. Forewing ochreous, in the marginal area with slightly darker veins; antemedian line straight, broadly edged with white, finely with blackish; at the cross-vein a darker spot; posterior transverse line distantly remote from the margin, quite straight, broad white, outside very narrowly bordered with brownish ochreous, at the inner margin almost united with the anterior line; in the broad marginal area an irregularly undulated whitish subterminal line is distinctly visible. Hindwing somewhat lighter than forewing. Type: 1 ♀ from Medina (Eastern Colombia) in the Coll. BANG-HAAS.

obliqua.

D. obliqua *Bouv.* (117 A a). Forewing light reddish yellow, often with fine darker veins, dusted with brown or grey, particularly behind the antemedian line, cross-vein, and subterminally, and a little before the margin; anterior transverse line short, convex, below the median vein and on 1 almost angular, black, crossed by 2 yellow veins, the basal area lighter; cross-vein dark, in the middle strongly introangular; posterior transverse line characterized by its oblique course, at the costal margin much nearer to the apex than at the inner margin to the tornus, little white, outside intensely black, traversed by orange and almost undulate-dentate. Hindwing generally still darker than the subterminal area of the forewing. Abdomen orange, with narrow black rings, laterally black with white spots. Peru; Bolivia.

gregatus.

D. gregatus *Bouv.* is known to me only from the description and figure. It is said to be closely allied to *peruvianus*; more dingy grey above a pink ground-colour, the veins scarcely darker; anterior transverse line inside at the inner margin with small black spots; posterior transverse line inside and outside bordered with black, only narrowly traversed by yellowish, with a very narrow white costal-marginal spot. Shape of wings shorter and broader than in the other species. Venezuela. Larvae in an oval bag of 15 to 20 cm length, light grey, with both ends open, fastened with a stalk at the end of a branch by using neighbouring leaves. The bag contains 10 to 12 cocoons. Larva itself green with stellately arranged tufts of red-brown thorns with black tips. It lives on "Mamon".

biremis.

D. biremis *sp. n.* (117 A a) is a large species. Thorax blackish-brown, abdomen orange with broad velvety black rings, ventrum black, laterally with white spots, anus rusty red. Forewing dark brown, with black veins; antemedian line broad white, outside broadly inside feebly bordered with black, traversed by 3 yellow veins, the cross-vein is a black angle; posterior transverse line slightly curved, white, on both sides very broadly bordered with black and broadly traversed by orange vein-rays of 6 to 8 mm length; subterminal line marked by the contrast with the lighter marginal area, receding between 4 and 5 as far as the postmedian line; fringe rusty brown, hindwing with a faded, slightly darker postmedian shadowy band. According to 2 ♀♀, type from Sa. Catharina in the Coll. W. HOPP, Charlottenburg, another specimen from Macas (Ecuador) in the Coll. NIEPELT.

albosignatus.

D. albosignatus *Bouv.* was not before me. Forewing smoke-brown, somewhat lighter than in *infuscatus*, with scarcely darker veins; cross-vein and discal spot feebly flawed a little above the centre, before it a white spot; anterior transverse line somewhat zigzag-shaped, rather indistinct; postmedian line parallel to the distal margin, somewhat more convex than the latter, almost quite black, without any white, the yellow traversing veins very feeble; it cuts vein 4 behind its middle; the undulate subterminal line is quite indistinct. Described from Venezuela.

niceros.

D. niceros *Dogn.* (117 D e). Forewing black with a chestnut-brown reflection and 2 white transverse lines, the first extending from the base of the costal margin obliquely distad and being interrupted below the median vein and at the inner margin; the posterior line is parallel to the margin, subterminal, interrupted by the veins and vanishing towards the apex. Hindwing as forewing with the continuation of the subterminal line which is here distinct and not interrupted by the veins, extending to the inner margin; the black thorax is intermixed with ochreous hairs; abdomen black with yellow rings, with a lateral row of white dots. Northern Peru (Huancabamba).

albilinea.

D. albilinea *Schs.* (103 A b). Head and thorax light brown, abdomen above ochreous, beneath light brown, with a lateral row of black, blue-centred spots. Forewing light brown, with fine ochreous veins, with a white diffuse spot in the cell; from the base of the costal margin an oblique dark line extends to the inner margin, being interrupted below the cell by a broad white stripe which extends from the base almost to the margin where it meets a white, darker brown-edged stripe proceeding from the costal margin from near the apex. Hindwing with a very feeble whitish distal band. Goyas, Brazil.

VII. albata-group.

albata.

D. albata *n. sp.* (*Maass. i. l.*) (117 A a). A very peculiar insect. Head and prothorax ochreous, palpi black, antennae smoky brown; the absent abdomen (a wrong one has been glued on the type) is presumably

ochreous with black rings. Wings white, the forewing at the apex and margin broad smoke-brown, between 2 and 4 somewhat narrower. Costal margin black, veins especially towards the margin smoky, at the cell-end a small black spot. Hindwing all white with a narrow smoke-brown marginal line. Type: 1 ♂ from Mexico in the Berlin Museum e Coll. MAASSEN, on the label "*Heliconisa albata*" has been written. I could not discover any description.

VIII. calchas-group.

D. calchas *Stoll* (117 A b) is the chief representative of a group of allied species the ♂♂ of which mostly *calchas*. exhibit a dark triangular spot at the costal margin, whilst the ♀♀ have a broad median band instead of it. Anterior body dark brown, abdomen reddish-yellow, with broad black bands. Forewing greyish-brown with a dark basal spot which is outside white-haired, a dark discal spot and above it a mostly small dark brown triangle with whitish edges; subterminal line dark, distally with a more distinct undulating border, receding between 4 and 6, proceeding between 2 and 4 in two obtuse bows. Hindwing basally bright red-brown with a large dark discal spot, a black postmedian line behind which generally a lighter band follows and then a darker subterminal band. The costal triangular spot may be almost quite absent, but also fused with the discal spot. The ♀ is mostly of a duller greyish-brown with 2 dark transverse lines bordered with whitish on the averted sides. Hindwing in the basal half less bright red-brown. Brazil (Sa. Catharina; Rio Grande do Sul; Porto Alegre).

D. rothschildi *Dogn.* (117 A b) is very similar to *calchas*, but easily discernible by the almost entirely *rothschildi*. black hindwings, and the black abdomen showing only very narrow brownish rings. Thorax and the oblique basal area much deeper black. The discal spot of the forewing is larger and black, mostly coherent with the black costal-marginal triangle. Brazil (Sao Paulo; Joinville).

D. fornax *Drc.* was not before me; it must be extraordinarily similar to *rothschildi*. Body blackish- *fornax*. brown, abdomen with long grey hairs. Forewing reddish-brown, densely strewn with grey, with a black oblique basal spot, a large black triangular spot in the centre of the costal margin and a round discal spot below it. Hindwing blackish-brown, in the distal half more reddish-brown, strewn with grey, with a narrow dark brown submarginal band therein. Under surface dark greyish-brown, with a narrow greyish-white median line. Expanse of wings: 4½ ins. Southern Brazil (Rio Grande do Sul).

D. thliptophana *Fldr.* (117 A c) is extremely similar to *calchas*, the costal-marginal spot sandglass- *thliptophana*. shaped, with or without a white central spot therein, the lower edge of the spot extending from proximally below obliquely, in a straight line upward distally. Hindwing almost exactly as in *calchas*. WEYMER described a specimen as the ♀ of it, which, however, according to the description I consider to belong rather to the *ursina*-group. The ♂ described by him probably also belongs rather to *calchas*. Amazons.

D. fraterna *Fldr.* (117 A c) is very similar to the preceding species. Forewing more cinnamon-brown *fraterna*. with a pink tint, the large discal spot is very broad at the costal margin, in the middle slightly strangulated, the lower edge with an almost rectangular point extending down to vein 2, bordered with whitish, with a white angular or comma-shaped streak near the exterior edge or also only a small white spot; marginal area lighter towards the subterminal shadow which is indented between 4 and 6. Hindwing as in the preceding species, with much duller transverse lines; a dark discal spot with a light ring may be present or absent. Amazons (Iquitos; Matto Grosso); Peru. — A Colombian form: **callosa** *f. n.* (117 A c), from Villavicencio, has broader *callosa*. wings and is more greyish-brown, the hindwing also without any red-brown; discal spot of forewing much deeper strangulated, producing outside and inside almost right angles; the enclosed white central streak is therefore also rectangularly flawed, the lower branch yellowish-brown, finely filled with black, only the upper branch white; marginal area with a yellowish ochreous tint. Hindwing beneath with a broad lilac white, distally concave median band which is only indicated in the typical form.

D. javarina *Btlr.* was not at hand; it is allied to *avia* and *concolor*. Forewing above light cinnamon *javarina*. pinkish brown, with a broad chocolate median band, at the costal margin thrice as broad as at the inner margin, the proximal border oblique and undulated, the distal border straighter; base dusted with brown, the basal area itself black, outside bordered by a white line; subterminal band darker brown, expanded in its upper quarter, apex before it mixed with yellowish. Hindwing basally reddish-brown, distal half more pinkish-brown, inside regularly bordered by the ground-colour. Thorax dark chocolate, abdomen rusty brown, laterally deep red, at the base with 2 black belts. Expanse of wings: 5 ins. 4 lines. Rio Javary.

D. avia *Stoll* and the following forms of it are rather variable. Dr. JORDAN writes to me that STOLL's *avia*. figure is inaccurate and the 3 bands on the hindwings are a mistake of the painter, since the hindwing above exhibits but one distinct blackish submarginal band, though between it and the cell there are sometimes traces of another band, and the 3 bands of STOLL are to be explained by the darkening of the centre of the wing. In the British Museum, according to the kind information by TAMS, *avia* is united with *orasia* *Stoll*; he says that the figure of *orasia* has been made from a very small ♀ or from a ♂ without antennae which the artist has added according to his own opinion. — **avia** *Stoll* (= *orasia* *Stoll*, *concolor* *Wkr.*) (117 A d) is the oldest form *avia*.

described of a brownish-grey ground-colour with a somewhat more prominently dark median band of a variable width, at the margins edged by whitish lines which gradually pass into the brown ground towards the averted sides; the somewhat irregular subterminal band is widened towards the costa and darker. Hindwing at the base feebly red-brown, with a narrow blackish submarginal band bordered lighter on both sides. Abdomen as in all the allies black with orange bands, especially in the ♀ intermixed with very long greyish-white hairs. Panama; *nora*. Colombia; Venezuela; Guiana; Eastern Peru; Trinidad. — *nora* Drc. (117 A c, d) is the mostly somewhat smaller form with a much lighter pinkish-brown ground-colour; especially in the ♂ the median band is reduced to a chestnut-brown costal triangle, sometimes, as in the figured specimen with an inner-marginal spot besides, more rarely with a distinct median band which is almost invariably present in the ♀. The type is from Panama; *triangulum*. distributed as far as Colombia. — *triangulum* Wkr. (117 A d) denotes specimens of a more violettish-grey ground-colour with a distinct olive green colouring of the costal-marginal triangle resp. median band; the subterminal band also shows a greenish tint; in both sexes the triangular spot may be widened into a median band, in any case they are bordered with a lighter lilac whitish colour. Hindwing at the base sometimes very bright rusty red. Mexico to Brazil and Bolivia. All the said forms are not distinctly defined, but extremely variable in colour as well as the development and size of the costal-marginal triangle or the median band, so that, if there are a sufficient number of specimens at hand, one may have all sorts of transitions. Nor is the neurulation constant (cf. p. 764), but most variable. On superficially examining the forms I found the uncus of the ♂ to be of the same shape in all the three forms.

dentimaculata. **D. dentimaculata** Schs. Anterior body dark brown intermixed with yellowish-white hairs, frons light brown; abdomen orange with black bands. Forewing light ochreous, with the exception of the marginal area thickly strewn with brown, a dark brown postmedian shadow fadedly passes over into the marginal area; in the centre of the costal margin a large brown triangular spot bordered at first with black, then with white, proximad deeply strangulated and distad with 3 short projections. Hindwing brownish with blackish-brown postmedian and subterminal shadows, the space between them being ochreous like the margin, and strewn with brown. Under surface light ochreous with feeble greyish-brown postmedian and subterminal shadows. Expanse of wings: 80 mm. Brazil.

hortensia. **D. hortensia** Schs. (117 B a). Thorax olive with light brown hair, abdomen brownish-red, with black bands. Forewing yellowish reddish-grey, strewn with olive and with irregular fine horizontal striae; an indistinct subterminal shadow, below the costal margin widened into a darker shadow; centre of costal margin with a large olive brown, lighter haired triangular spot, bordered with black, enclosing a black discal streak, the distal border being feebly undulated. Hindwing at the base and inner margin brown, outside and towards the costal margin darker shaded, with a dark discal spot and a blackish-brown postmedian and subterminal shadow, marginal area as on forewing. Sao Paulo (Brazil).

muscosa. **D. muscosa** Schs. (117 B a) is apparently more common, very similar to *hortensia* in the olive greenish ground-colour; the costal triangle is chiefly developed into a narrowed band extending to the inner margin and being outside and inside strongly dentate; its black border is besides mostly bordered outside with whitish; hindwing at the base of a brighter brown, the discal spot and the two anteterminal lines very thick and distinct. Abdomen bright rusty red with black bands and intermixed with long light yellowish-grey hairs. Colouring and marking most variable, often very dark blackish-green, particularly the ♀♀ are frequently intensely intermixed with white, the median band is often very broad, often narrow, occasionally interrupted above the inner margin, so that there is a small isolated inner-marginal spot is left, which may also be absent, so that only the costal triangle is present. Venezuela to South Brazil, a great many specimens being at hand.

curitiba. **D. curitiba** sp. n. (117 B b) is evidently very closely allied to *muscosa*, but smaller, the ground-colour basally and in the marginal area more lilac-grey, as in *triangulum*, only the broad median band being olive brown; the coarse striation and strewing of the preceding species is entirely absent; the median band is on both sides regularly though flatly dentate, scarcely bordered with black, but on both sides bordered with a whitish line; the black discal spot indistinct and much less obliquely arranged; the darker subterminal shadowy band is very faint and almost rectilinearly defined, whereas in *muscosa* it recedes far between 4 and 6. Hindwing brown, towards the base yellowish ochreous, the 2 anteterminal nebulous bands very feeble, the discal spot being absent altogether. According to 2 ♂♂ from Curitiba, type in the Senckenberg Museum, Frankfurt o. M. In the co-type the median band is scarcely dentate.

jorgenseni. **D. jorgenseni** Schs. The black body is scantily intermixed with yellow hairs; antennae yellow. The light ochreous ground of the wings is strewn with brown; forewing at the base narrowly black, the fine black transverse lines are feebly denticulate, the antemedian line is excurved at the costal margin, then vertical, the posterior line excurved at the costal margin then somewhat incurved; at the cross-vein a small black spot; marginal area somewhat lighter, at the apex narrow, between 4 and 6 broad. Hindwing with a short black discal line and a blackish-brown postmedian shadow. Expanse of wings: 90 mm. Argentina (La Junta).

baroma. **D. baroma** Schs. was not before me. ♂ forewing reddish-brown, dusted with blackish as far as the subterminal line projecting in roundish bows between the veins of the marginal area; at the cell-end a round black, grey-encircled dot; base red-brown, bordered by an oblique white line. Hindwing in the basal half reddish, at

the margin more brownish, at the base with brighter red hair; discal dot and a curved median line dark brown, behind it a rosy-reddish area and a broad dark brown distal band. The ♀ shows 2 distinct dark brown transverse lines, the anterior one subcostally angled, inside bordered with whitish, between them a feeble brown discal dot. Hindwing lighter red than in the ♂, the bands faded and nearer to the margin. Abdomen ochreous brown with black abdominal belts and long white hairs. Expanse of wings: ♂ 90, ♀ 115 mm. Patria unknown.

D. ursina Wkr. (117 B b). Forewing on the yellowish-brown ground densely and finely strewn with a darker brown, the small oblique basal area dark brown, 2 transverse lines somewhat convergent towards the inner margin are fine dark brown, very feebly denticulate, in the narrow median area at the upper cell-angle a small white spot, at the lower one a small black spot in a whitish ring; marginal area somewhat lighter towards the subterminal area, receding between 4 and 6, below it once more in 2 short bows. Hindwing generally towards the base darker, with 2 nebulous bands in the lighter marginal area and a small faint discal spot. Abdomen above black with narrow reddish-brown rings. Brazil.

D. avicula sp. n. (117 B b) is somewhat allied to *ursina*. Ground-colour varying between light brownish-grey and light red-brown, very finely strewn darker, the median band prominently darker, still darker than the broad subterminal shadow behind it; the anterior transverse line is flawed in an obtuse angle, the exterior line almost straight, very slightly curved S-like, in the upper half convex towards the margin, in the lower half towards the base, both on the averted sides more or less bordered with whitish; in the upper cell-angle a small white spot which may also be absent, in the lower one a black spot; subterminal shadow as in *ursina* in contrast with the likewise somewhat similar *curitiba*. Hindwing more scantily scaled greyish-brown, at the base with reddish flesh-coloured hairs; discal spot quite indistinct, the two anteterminal lines as in *ursina*, marginal area like the forewing slightly strewn. Thorax blackish-brown, abdomen above quite black, beneath brown, anus bright brownish-red. Described from 3 ♂♂, 1 ♀. ♂ type from Paraguay bred from a not described larva on *Rapanea laetevirens*; ♀ type from Sao Paulo, both in the Berlin Museum; co-type 1 very large contrasting ♂ from the Rio Songo, Bolivia, a third more red-brown ♂ from Brazil, the exact habitat not being mentioned.

D. parallela Schs. (118 e) is ochreous grey on the forewing, darkest in the marginal third, with blackish-brown thick parallel transverse lines; the posterior line very indistinct, feebly bent at the costal margin; discal dot black; the subterminal line is an irregular narrow brownish-grey shadow. Hindwing greyish-brown, dusted darker with a broad black postmedian line and an indistinct subterminal shadow, at the base with some ochreous hairs. The brownish-grey forewing exhibits beneath a feeble dark shadow from the apex obliquely to $\frac{2}{3}$ inner margin. Anterior body brownish-grey, abdomen black with orange segmental lines. Expanse of wings: 105 mm. South-Eastern Brazil (Joinville). The species in my opinion is much more allied to *hircia*, especially its form *arcaeii*; I have left it here merely on account of the neurulation (6 and 7 of forewing from the same place) of the only specimen at hand.

D. quaesita sp. n. (118 e) is more like the *hircia*-group, but according to the neurulation it belongs also to this group here. Anterior body blackish-brown, abdomen orange with black rings; forewing blackish-brown, scantily strewn with bluish-white hair-scales which are somewhat condensed on the proximal sides of both the thick black transverse lines; on the lower discocellular a thick black spot; subterminal line likewise marked by more densely strewn bluish-white scales, behind it clouded darker blackish-brown. Hindwing more scantily scaled, not strewn, with a thick black discal spot and a black subterminal line; fringe white. Type: 1 ♀ from the Rio Jacula near Rio Patia (Colombia) in the Coll. HOPP, Charlottenburg.

IX. *somniculosa*-group (*Plateia* Hbn.).

D. somniculosa Cr. (117 B b, c). A very large and unmistakable species. ♂ red-brown with 2 lilac white transverse lines which are slightly convergent towards the inner margin, the anterior one subcostally interrupted, and obtusely angled on the median vein; in the marginal area besides with 2 broad indistinct light nebulous bands; hindwing scarcely lighter, with or without a discal spot, with a light subterminal band. Thorax dark red-brown, metathorax and base of abdomen red-haired, abdomen black with orange rings. ♀ usually darker and very large, expanse of wings as wide as 140 mm. Guiana; Venezuela; Colombia.

D. theobromana sp. n. (117 B c) is a transition to the following species; anterior body dark red-brown, abdomen orange, above with black belts. Forewing chocolate brown, basally and subterminally strewn with white, the short oblique basal area is coloured like the thorax and outside bordered with whitish; both the transverse lines are indistinctly darker, on the averted sides bordered with lilac whitish, the anterior line subcostally and on 1 angled in a basally open angle, the posterior line feebly dentate inwards on the veins, towards the costal margin indistinctly widened; subterminal line of the same shape as in *panamensis*. Hindwing scarcely marked except 2 very indistinct anteterminal shadows between which the ground is somewhat lighter lilac whitish. Type: 1 ♀ from Villavicencio (Eastern Colombia) in the Coll. BANG-HAAS. A similar, somewhat smaller ♀ from Southern Colombia, Mocoa, e Coll. NIEPELT.

panamensis. **D. panamensis** Schs. Head and base of abdomen reddish-brown, thorax lilac grey; abdomen above orange with black bands. Forewing purple grey with a curved lilac whitish antemedian shadow and a similar feebly curved postmedian shadow; at the oblique cross-vein a fine black line; marginal area lilac white, at the apex and anal angle very narrow. Hindwing lilac whitish, at the base with light reddish hair, with a broad purple grey subterminal shadow. Expanse of wings: 98 mm. Described from a ♀ from Panama.

fassli. **D. fassli** Dogn. (117 B d) is very similar to *panamensis*; thorax red-brown, head and collar lighter reddish; abdomen above black, base, ventrum and anus rusty brown. Forewing lilac whitish, a small oblique basal area and the median area brownish with an oval brownish small discal spot; postmedian line feebly S-curved, inwards broadly dusted with lilac white like the marginal area behind the feebly curved broad brownish subterminal shadow. Abdomen whitish, feebly dusted with brownish, with an extinct discal spot and 2 very indistinct anteterminal shadows. Colombia, Bolivia.

X. arpi-group.

arpi. **D. arpi** Schs. (= *satanas* Jones) (119 a). A beautiful large, quite isolated species, most peculiarly marked. Forewing blackish-brown, cell-end filled with black; antemedian line irregular, projecting far in the cell, below it interrupted and continued to the base. Postmedian line receding almost to the cell in a long bow below 4 and 6, projecting towards the margin in 2 bows between 2 and 4, outside light, filled with almost white. Hindwing with a broad brownish ochreous median band which is generally very dark, in — *seitzi* f. n. *zikani*. (119 a) bright orange, in — *zikani* f. n. greyish-white. The larger ♀ is more monotonous, behind the postmedian line fawn-coloured, the band of the hindwing much narrower, nearer to the margin, between 2 and 3 notched. Hindwing beneath covered with long stiff vertical hair as in the genus *Megathymus*. The larva is opal-white or cinnamon-red with a black X-shaped dorsal marking and white spines, with black tips. It lives on *Rapanea flocculosa* and *Eucalyptus*; in the day-time it hides on the trunk and pupates in a web between leaves. Southern Brazil.

(?) *Dirphia lauta* Berg has remained unknown to me. According to the description it is a small insect the forewing of which is only 27 mm long. Body covered with long ochreous hair, intermixed with greyish-white hair, head and thorax more rusty red, abdominal segments with somewhat darker rings. Wings very scantily scaled, dingy white without markings, costal margin beneath as well as the legs yellow. Rio Negro (Argentina). I doubt whether it is a Saturnid at all. Mr KÖHLER had the kindness to search for the type, but it could not be discovered.

Nothing could be found out about the „*Dirphia*“ *nubila*, *satellitica*, *purpurascens*, *undulosa* described by WALKER, from the Coll. FRY: the types seem to have been lost and the descriptions are quite insufficient. Part of them may be *Syssphinxidae*.

16. Genus: **Catocephala** Blch.

This genus comprises a small group of rather closely allied species, mostly from the southernmost parts of America, distinguished by the veins 6 and 7 of both wings arising from one and the same place or on a short stalk; the variability, however, is here also rather great in individual specimens. Shape of wings generally somewhat narrower, especially in the ♀♀. Thorax loosely haired, intermixed with long, partly oar-shaped hairs. Abdomen of the ♂♂ projecting but little beyond the hindwing, in the ♀♀ more so. Antennae of the ♂♂ with long pectinations, in the ♀♀ shortly serrate-dentate with short spiny bristles. All of the species are very variable; BOUVIER has written a short monography on them which, however, does not state all the differences which occur in large series.

Type: *amphinome* F.

I. Group: abdomen above with spatulate hairs (*Catocephala*).

amphinome. **C. amphinome** F. (= *humeralis* Wkr., *hyadesi* Mab.). Forewing cinnamon red-brown with 2 notched transverse lines inwards edged with a very faint whitish colour, between them a large yellow discal spot which is outside thrice notched; subterminal line indistinct. Hindwing with 2 blackish transverse lines, feebly notched and bent on 5. Abdomen above black with narrow yellow segmental margins, a rusty yellow base and anus. Southernmost Chile and Fuegia.

rufosignata. **C. rufosignata** Blch. is allied to the preceding species and distinguished by the dark cinnamon red colour, more sharply notched transverse lines without any white, with a white instead of yellow cellular spot. Southern Chile.

marginata. **C. marginata** Phil. (117 B d) is likewise very similar to *rufosignata*, lighter, the ♂ more greyish-red, the two transverse lines less notched, on the inverted sides broadly edged with whitish; cellular spot in the centre white, then yellow and outside edged somewhat blackish; subterminal line much stronger, blackish, strongly and irregularly notched, and outside bordered with whitish. Hindwing with 2 broad blackish transverse bands which are much less curved than in the preceding species. Abdomen in both sexes above almost entirely black, only narrowly bordered with yellow. Chile.

patagonica. **C. patagonica** Bouv., only recently described, was not before me. Size of *amphinome* and its allies. Body light brownish yellow, hairs of patagia with whitish tips, abdomen somewhat more yellow, very scantily

intermixed with yellow hairs, only the last 2 rings with black bands. Forewing yellowish-white, basally somewhat brownish, only a double yellowish feeble postmedian line is present, being regularly dentate, parallel to the margin, at the costal margin the portions are somewhat more separated; at the cell-end a chalk-white discal erecent surrounded by black; cross-vein below the rise of vein 5 introangular. Hindwing without a cellular spot and lines. Patagonia.

C. vulpina Phil. (117 C a). Ground-colour light greyish-white, feebly mixed with yellowish-brown; *vulpina*. transverse lines very similar to those of the preceding species; discal spot white surrounded by blackish; subterminal band black, strongly notched, towards the costal margin ending into the apex, the margin behind it, especially at the apex and tornus almost white. Hindwing light yellowish-white with 2 faint transverse bands, particularly the interior one almost extinct, the exterior one often broader and darker. Thorax grey, in the centre fox-coloured, abdomen above black, with narrow yellow rings; anus fox-coloured. Chile.

C. nigrolutea Bouv. is another smaller species distinguished by the yellow ground-colour of the forewing. *nigrolutea*. Forewing relatively narrow, in some places of the yellow ground strewn with a blackish grey; veins scarcely darker; transverse lines as in *vulpina*, the discal spot somewhat oval, yellowish-white; submarginal line less irregular, less sharply defined than in the other species, distally to it between the veins large black marginal spots; fringes in both wings yellow. Body quite black, also the ventral side, only the anus and lateral segmental lines yellow like the head; the spatulate hairs on the thorax have yellow tips. Expanse of wings: 55 mm. Described according to 4 ♂♂ from Patagonia.

C. lupina sp. n. (117 C a) is very similar to the preceding species, forewing more intensely dusted with *lupina*. black, in the whole marginal area somewhat more ochreous; transverse lines more separated, the anterior one on the median vein and vein 1 with very long and pointed distal notches, the posterior one straight, near the margin, in *vulpina* more curved and at the costal margin bent inwards. Hindwing at the margin broadly smoked, enclosing a white undulate subterminal line which is especially distinct in the ♀. Abdomen above quite black, laterally, beneath and at the anus rusty yellow. According to a couple from Chile, from the Coll. BANG-HAAS.

C. murina sp. n. (117 C a) has narrower wings than the species hitherto known, scantily scaled and of a *murina*. monotonous sooty black colour; both the flatly notched transverse stripes are similar as in the following *nigrosignata*, especially the antemedian one at the costal margin expanded into a small grey spots; the small crescentiform cellular spot in a darker longitudinal patch; subterminal line scarcely recognizable. Hindwing more scantily scaled, semidiaphanous grey, without markings, fringe darker. Body greyish-black, abdomen with few yellowish-grey hairs. Chile (Valdivia); type 1 ♀ e Coll. STGR. in the Berlin Museum.

C. nigrosignata Phil. (= *luperina* Pack. ? i. l.) (117 C a). Forewing on the greyish-white ground strewn *nigrosignata*. with black, basally and in the marginal area mostly brownish-ochreous; the notched transverse lines are expanded into spots at the costal margin, on the inverted sides bordered with white; the whitish subterminal line close before the margin which is crossed by black vein-triangles. Hindwing pale yellowish-grey, in the marginal half more brownish, with 2 postmedian transverse bands, the interior one mostly narrower, between 4 and 5 far produced towards the margin; margin and fringe crossed by black vein-triangles. Abdomen above almost black, base, ventrum and anus rusty brown. Chile (Valdivia). In the Senckenberg Museum, Frankfurt on the Main, a couple labeled: "*luperina*", which name presumably refers to the note and sketch of the neuration in PACKARD'S Monography 1914.

II. Group: abdomen above without spatulate hairs: (*Thauma* H.-Edw.).

C. joiceyi Bouv. ined. (117 B d) and the following species form a special group: cinnamon-brown; *joiceyi*. thorax intermixed with whitish-grey hairs, abdomen more yellowish-brown. Forewing with 2 very deeply notched black transverse lines, on the inverted sides, especially at the costal margin, bordered with white, and between them a large yolk-coloured, outside and inside tridentate discal spot; median area often somewhat blackish; subterminal line hardly discernible. Hindwing less scaled, greyer with traces of a yellow discal spot, and a feeble black postmedian line and a very indistinct or absent subterminal line. Chile. In the Berlin Museum 3 ♀♀ and 1 ♂ from Valdivia and Puerto Montt, in the Hill Museum according to the kind information by BOUVIER 2 ♀♀, 1 ♂. We gladly avail ourselves of the opportunity of keeping up the name proposed by the latter author, so as to express our gratitude to the owner of the Hill Museum who provided us, by Mr. TALBOT, with many valuable explanations and many figures of types.

C. socialis Feisth. (= *angulifera* Wkr., *ribesii* H.-Edw., *ribis* Ky.) (117 C b). For this species the genus *socialis*. *Thauma* was established. Separated from *joiceyi* by the antennae being pectinated also in the ♀; the colour is cinnamon-brown, more or less hued with ash-grey; antemedian transverse line oblique, the posterior one near the costal margin bent towards the apex, both on the inverted sides bordered with white; at the cell-end a white triangular spot, on the median vein more or less produced towards the base. Hindwing with a white discal streak and behind it a grey transverse line or band. Abdomen reddish-yellow, in the redder ♂ with black rings. Chile; Peru, and most peculiarly reported (presumably imported) from North America (Brit. Columbia). Larva above light green, beneath light red or green, with a white lateral line edged with red-brown; on each

ring stellarily arranged tufts of nettling spines, being longest on the 2nd and 3rd rings. On *Cryptoearya peumus*. Often in great numbers though not gregariously. Pupa in a loose cocoon beneath shrubs or in the ground.

16. Genus: **Ormiscodes** *Blch.*

Only 2 species, of the same structure as the preceding ones, but much larger, and the distal margin of the forewing usually feebly concave, especially in the ♂♂.

Type: *O. cinnamomea* *Feisth.*

cinnamomea.

O. cinnamomea *Feisth.* (= *crinita* *Blch.*, *plana* *Wkr.*) (117 C b). Forewing cinnamon-brown, intensely strewn with greyish-white, with 2 almost straight dark brown transverse lines, the anterior one somewhat excurved below the costal margin, both on the inverted sides bordered with white; between them a broad cinnamon-red median shadow which is connected with the antemedian line at the inner margin and contains, at the cell-end, a large white, centrally somewhat strangulated or bipartite spot. Hindwing light brown with a whitish discal streak and a grey nebulous line behind it. Abdomen black with bare ochreous ring-indentations and brownish-pink basal hair. Larva black with interrupted yellow transverse bands and long tufts of brown spines with a severely burning effect. On *Mühlenbeckia*, poplars, pepper-tree, roses, and many other trees and shrubs. Pupa in a loose cocoon between leaves on the ground. Chile.

cognata.

O. cognata *Phil.* (= *alanus* *Pack. & Ckll.*) (117 C b, c) is allied to *cinnamomea*, of a purer brown without the greyish-white strewing, the ♂♂ sometimes deep blackish-brown, also yellowish-brown; more variable than *cinnamomea*; the transverse lines not bordered with white, the anterior line much less distinct; the white discal spot is much smaller, mostly only punctiform. Hindwing with more intense postmedian bands, often also the submarginal line very broad and black, whilst in *cinnamomea* it is almost absent. Abdomen blacker, basally not brownish-pink, but rusty yellow like the ventrum and anus. It is probably a distinct species; in the ♂ the ventrally reverted, deep black chitinized tip of the uncus is more deeply and pointedly bidentate, the harps are broader and divided into 2 more unequal lobes than in *cinnamomea*.

17. Genus: **Hidripa** *gen. nov.*

The few species belonging to this genus are chiefly distinguished by the peculiar hairiness of the ♀ abdomen forming at the end an anal tuft which is predominantly developed laterally and beneath and extends laterally in long woolly locks, like a coat, to the base of the abdomen. Neuration not quite constant, but on the hindwing 5 and 6 almost invariably arise from the same place or at least very close together. Moreover, the species hitherto known are distinguished by a narrow yellow ring around the eye-like discal spot of the hindwing.

Type: *H. ruscheweyhi* *Berg.*

ruscheweyhi.

H. ruscheweyhi *Berg* (117 C c) is on both wings sooty brownish or blackish; forewing with a darkened basal area, the antemedian line on each side bordered with whitish and twice distally sinuate, the similar postmedian line being undulately dentate, between them a large jet-black angular spot at the cross-vein and median vein, scaled white and finely bordered with yellow; subterminal line feeble and interrupted. Hindwing without an antemedian line, with 2 irregularly notched postmedian bands, the subterminal line broader and less distinct, the thick black discal spot with a whitish central streak and a yellow ring. Abdomen sooty black. The ♀ with silvery grey ventral lateral wool. Paraguay and Argentina.

gschwandneri.

H. gschwandneri *sp. n.* (117 C c) is more than twice as large; ground-colour lighter brownish, basal area very dark, antemedian line almost straight, not arched, and in an oblique distal direction to the costal margin, outside bordered with yellowish; the V at the cell-end is more slanting and more acute-angled; postmedian line less dentate. Hindwing almost as in *ruscheweyhi*. Abdomen brown, anus brownish-pink. Type: 1 ♂ from the Chaco (La Paz), Bolivia, in the Berlin Museum. A similar specimen in the Coll. GSCHWANDNER.

weymeri.

H. weymeri *sp. n.* (117 C c). Forewing greyish-brown, with a feeble reddish tint, basal area like the thorax dark brown, the former subcostally projecting pointedly towards the margin, behind it a broad area of lilac grey dusting, distally gradually passing into the median area, without an antemedian line; the angular streak at the cell-end finer than in the two preceding species; the feebly notched postmedian line is outside narrowly bordered with whitish lilac; the narrow dark subterminal line is distally round-arched between 2 and 4. Discal eye of hindwing small and narrow, with a hardly noticeable yellowish border, the two anteterminal lines outside intensely bordered with lilac white. Patagia with long lilac white hair. Abdomen basally and at the anus copper pink. Type: 1 ♂ from Joinville e Coll. WEYMER in the Berlin Museum, co-type from Passa Quatro (Minas) in the Coll. HOPP-Charlottenburg.

H. taglia Schs. (117 C c). Forewing marked almost exactly like *gschwandneri*, the antemedian line *taglia*. likewise oblique, the discal spot in its upper portion thicker, with a yellow central streak, the lower portion very short and narrow. Hindwing as in *ruscheweyhi*, the eye much larger and with a broader yellow border. Abdomen red, beneath brown, in the ♀ with lateral white hair. South-Eastern Brazil (S. Paulo).

H. perdix Maass. (117 C d) is marked like the preceding ones, but lighter brown, the strongly notched *perdix*. transverse lines on both sides broadly bordered with whitish or pinkish-white; subterminal area darker brown in contrast with the marginal area which is mixed with whitish; discal streak in the upper portion intensely edged with white; adjoining to the median vein and vein 2 an intense, horizontal black V-mark. Eye of hindwing smaller, subterminal shadow very broad. Fringe speckled yellowish-white and blackish-brown. Brazil (Novo Friburgo; Joinville).

H. albipellis sp. n. (117 C d) is still larger than *gschwandneri* and very different. Forewing sooty blackish; *albipellis*. both the transverse lines of the forewing whitish-grey, feebly bent, the posterior line distally angled on 7, dentate between 2 and the inner margin, subterminal line defined towards the somewhat lighter marginal area; veins of marginal area fine black. Hindwing somewhat more scantily scaled, the discal eye oval, small, black with a white central streak in a yellow ring, behind it a dark undulate postmedian line, then a white notched subterminal line. Abdomen black, centre of ventrum sooty grey, sides in the ♀ with a long and dense cover of yellowish-white hair. Type: 1 ♀ from the upper Madre de Dio, South Peru, in the Coll. BANG-HAAS.

18. Genus: **Dihirpa** gen. nov.

Only 1 species with broad wings; forewing with a characteristic course of vein 7 arising far off from 6 and far before the cell-end from the upper cell-margin. On the hindwing 5 and 6 arise nearly or quite from the same place; thorax with very long hair. Palpi well developed. Anterior tibiae with a well developed epiphysis attaining almost the length of the tibia.

D. litura Wkr. (= *marginella* Wkr.) (117 C e). Forewing olive brown, in some places, especially in the *litura*. costal posterior portion of the median area with ochreous hair; in the base of the cell a thick white longitudinal streak and at the cell-end a white discal streak, the upper end of which turns back a little; between the cell-end and the margin a deeply notched line distally bordered somewhat whitish; cell generally darkened, behind its end a very faint median shadow. Base of hindwing with light ochreous hair, the postmedian line less strongly notched; the white fringe on the ends of the veins mottled black. Abdomen black, on the posterior segments with ochreous rings of increasing width. The ♀ is less scaled and lighter, greyer. Colombia.

19. Genus: **Phricodia** Hb.

Very similar to *Dirphia* and of a scarcely different habitus, but separated by the remote origin of 6 and 7 on the forewing and of 5, 6 and 7 on the hindwing. Most of the species are characterized by the presence of 2 small discal spots of the forewing, one being white, the other one below it black. The type was considered to be *avia* Stoll, but as this species is by no means separable from *Dirphia*, we choose as type CRAMER's species *hircia*.

Type: *Ph. hircia* Cr.

I. *hircia*-group.

Ph. hircia Cr. (117 C e). Most variable, lighter or darker brown, or pinkish-brown with 2 strong transverse *hircia*. stripes bordered with white on the averted sides, the posterior stripe also proximally white, the anterior one bent, mostly subcostally angled, the posterior one almost straight; in the median area, which is sometimes feebly darkened, in the upper cell-angle a white discal spot, below it a black one; the darker subterminal line projects in a strong bow towards the margin, the farthest between 2 and 4. Hindwing with a hazy black discal spot and 2 blackish arcuate lines behind it. Fringe white. Abdomen ochreous with black rings. Mexico to Surinam and Colombia. — **rosacea** f. n. (117 C e) are distinctly pink specimens from Mexico. — Very similar *rosacea*. is **arcae** f. n. (117 C f) of which Mr. TALBOT of the Hill Museum kindly gave me a photo of the type, which most *arcae*. accurately corresponds with some specimens from Panama (Lino), and to some extent also with Colombian specimens from Muzo. The colour is a yellowish brown, the transverse lines are straighter, scarcely or not bent below the costal margin, the subterminal markings being so very distinct in the nomenclatural type are almost extinct, only marked by a somewhat darker marginal area. The type in which, moreover, 6 and 7 of the forewing are stalked, is very similar to *Dirphia parallela* (118 e), so that it seems to me to be almost the same species. — **obtusa** Wkr. (117 D a). Dr. JORDAN kindly sent me a sketch of the type of this almost unknown *obtusa*. species; a ♀ which we figure, from the Berlin Museum, seems to me to belong to it. Accordingly, it is so closely

allied to *arcae* that it can be scarcely separated; the apex of the forewing is somewhat more pointed, the transverse lines are just as little bent below the costal margin. Ground-colour browner, more irregularly mixed with ochreous, of the latter colour are spots especially before and behind the subterminal line; discal spots diminutive. Hindwing without a discal spot, more yellowish than the forewing, with 2 distantly separated postmedian and submarginal transverse lines. Abdomen brownish orange with black rings. Pará; before me from Surinam.

- amalia*. **Ph. amalia** Stoll. (117 C f) is very similar to *hircia*, but easily discernible by the undulate-dentate course of the posterior transverse line. According to the figure, the type is a small species, with a feebly dentate postmedian line. A very similar specimen from Pará, likewise named *amalia*, is before me from the Berlin Museum. Ground-colour light brownish ochreous, in the marginal area more violettish-grey; scheme of markings otherwise as in *hircia*, the median area scarcely darker, the subterminal line intensely marked as a notched line, with 2 double-pointed projections between 2 and 4, where it is outside distinctly bordered with whitish, before it spotted yellowish ochreous; upper marginal half darkened reddish-brown. Hindwing towards the margin feebly pinkish-brown with 2 separated grey postmedian nebulous bands and a faint discal spot. —
- afflata*. **afflata** Strd. (117 D a) certainly belongs as a subspecies to this place. It is larger, the postmedian line is stronger and more regularly notched, the median area broader, the upper white and lower black discal dot distinct. STRAND's type from Sarayacu (Ecuador) is somewhat lighter and more variegated than the figured specimens, from Mocoa (South Colombia), which I owe to the kindness of Mr. NIEPELT.

II. rosacordis-group.

- rosacordis*. **Ph. rosacordis** Wkr. (117 C f). Forewing reddish cinnamon brown with 2 broad straight blackish-grey antemedian and postmedian transverse stripes which are broadly bordered with light lilae pink on the inverted sides; behind the exterior stripe follows a straight brightening of the ground-colour, then the almost straight darker subterminal band which turns to the apex only above vein 7 and is outside broadly bordered with whitish pink again; a whitish strangulated discal streak is insignificant or absent. Hindwing at the base with somewhat more reddish ochreous hair, with or without a narrow blackish discal streak edged with yellowish-white, and 2 lilae pink subterminal bands enclosing a darker band. Abdomen black with narrow white rings, at the base pink, anus pinkish brown. Brazil.
- opis*. **Ph. opis** Schs. (117 D a) is very similar to *rosacordis*, but the colour is a darker brown on an average, the transverse stripes are not straight, but both at the costal margin bent to the base, the anterior one also at the inner margin, whereas the posterior one turns here towards the margin; the lilae pink border may be very broad, or also absent altogether; the yellowish-white discal streak has almost the shape of a sand-glass, it may also be absent; the subterminal band inclusive of its lilac pink marginal border is likewise more curved and extends from the apex to vein 4 obliquely inward and projects towards the margin between 4 and 2. Brazil, common (Sa. Catharina; Joinville; Parana).
- colax*. **Ph. colax** sp. n. (117 D b). Forewing of ♂ light coffee brown, transverse lines less curved than in *opis*, scarcely bent below the costal margin, much narrower and more distinct, but scarcely darker than the ground and on both sides narrowly and distinctly bordered with greyish-white, not quite straight, but unnoticeably undulate-dentate, the interior light border-line broader than the exterior one; discal streak black, bordered with yellowish-white. Subterminal line similar as in *opis*, but more irregularly notched, between 4 and 5 more or less interrupted. Hindwing in the basal half pink, behind it like the forewing, slightly hued with red, the interior band of the hindwing inwardly bordered with greyish white, behind it at the apex a whitish spot. Body as in *opis*. The ♀ is of a somewhat more red-brown ground-colour. According to a couple from Rio Grande do Sul in the Coll. BANG-HAAS.
- arpi*. **Ph. arpi** sp. n. (117 D b) is likewise similar; forewing broader olive brown, of the transverse lines only narrow violet reddish-grey lines are left, the anterior line somewhat undulate, the posterior one quite straight as in *rosacordis*; the very narrow discal streak is black, narrowly bordered with yellowish. Of the subterminal line only a light lilae apical spot distally bordering on it is present, the rest quite indistinct. Hindwing at the base bright pink, costal margin and distal half olive brown. Abdomen as in *opis*. Type: 1 ♂ from Rio de Janeiro, e Coll. ARP in the Senckenberg Museum, Frankfurt-on-Main.
- rubripes*. **Ph. rubripes** (Weym. i. l.) n. sp. (117 D b). ♂ quite dark, chocolate-brown with but one broad faded posterior transverse line of a blackish-grey colour, inwards hardly noticeably bordered with whitish and quite straight; discal spot as in *opis*. Hindwing at the base with a pink hue, likewise with a broad blackish-grey postmedian line and a very indistinct subterminal band. The ♀ is similarly marked, but the anterior body and wings are light ochreous, almost as in *Agria tau*-♀. Abdomen as in the other species of the group black with narrow white rings, at the base pink, in the ♀ with ochreous hair. Type: ♂ from Joinville, ♀ from Parana, both in the Berlin Museum.
- vagans*. **Ph. vagans** Wkr. (117 D c) is much smaller than the preceding ones, with more pointed and narrower wings. Ground-colour greyish-brown, with a slight ochreous hue subterminally, slightly darker transverse lines, the posterior one straight and rather oblique, passing close at the yellowish-white, mostly bipartite discal

spot; subterminal line of the same shape as in *opis*. Hindwing very feebly marked, fringe whitish. Abdomen black, with narrow white rings, at the base with pink hair, at the anus likewise yellowish-white, only at the extreme end rusty brownish. Brazil, widely distributed.

Ph. simplex *Dogn.* is similar to *vagans*, still smaller; anterior body brown, collar and metathorax pink, *simplex*. abdomen above darker brown. Wings light pinkish-brown, with a hardly darker posterior transverse line parallel to the margin; the cross-vein neither much darker. Described according to a ♂ from Novo Friburgo with an expanse of 57 mm.

III. plana-group.

Ph. plana *Wkr.* I cannot tell whether this species really belongs to this place; according to a sketch *plana*. of the type kindly sent by Dr. JORDAN, it is best ranged here judging from the neurulation. From WALKER's insufficient description which places the species to the *Lasiocampa* it could be scarcely identified. WALKER states the ground-colour to be reddish fawn on both wings, whilst according to JORDAN the forewing of the type is dingy yellow with dark veins, the hindwing pink, both wings with a white stigma on the cross-vein; forewing with a thin brownish shadowy band parallel to the margin, about 1 cm distant from it; hindwing likewise with a darker submarginal line. Expanse of wings: 32 lines. Haiti.

IV. lasiocampina-group.

Ph. lasiocampina *Fldr.* (117 D c). Wings coloured pale cinnamon-reddish, fringes and veins ochreous; *lasiocampina*. the white antemedian line, often reduced to 3 small vein-spots, is almost rectangularly flawed on the upper cell-margin, the posterior line parallel to the distal margin, slightly incurved between 2 and 4, feebly undulate-dentate between 5 and the costal margin. Hindwing paler. Abdomen black with ochreous rings. Mexico.

Ph. hoegei *Drc.* (117 D c) is very similar, larger, browner, especially the ♂♂ basally and subterminally *hoegei*. shaded with blackish grey, the white transverse lines broader, at the costal margin expanded into white spots, the posterior line more intensely undulate-dentate and outside bordered with very dark; veins not so yellow, more brownish-black like the fringe. Hindwing lighter with a distinct postmedian shadowy band being often bordered with white inside at the costal margin; the basal portion of the inner margin with yellowish ochreous hair. Mexico.

V. semirosea-group.

Ph. semirosea *Wkr.* (117 D d) to a certain degree resembles the preceding group by the same design *semirosea*. of markings, but the colours are different. The blackish-brown thoracal hair are intermixed with stiff grey hairs, abdomen black with pinkish carmine rings. Forewing blackish-brown, more or less hued with pinkish violet or carmine, with blackish-brown veins and internerval lines, with white transverse lines extending similarly as in *hoegei*, but more reduced to vein-dots, also the posterior line angled at 5, between the small white vein-spots orange, on both sides finely bordered with black, at the costal margin both the lines are widened into thick white dentate spots; median area especially in the costal-marginal half and at the inner margin darkened like the distally strongly notched subterminal line which recedes between 6 and 4 in an oblique line; marginal area especially subapically very light. Hindwing with 2 blackish postmedian shadowy bands, the interior one at the costal margin mostly with 2 small white vein-spots. Extreme purple-pink forms may be named — **roseana** *ab. nov.* (117 D d). The nomenclatural type flies from Mexico to Costa Rica. — In f. **gemeli** *roskana. gemeli.* *Bouv.* (117 D d), from Ecuador (Quito), Peru (Chanchamayo), Colombia, the black and smoky grey forewing is without any violettish-pink, the antennae are not light yellow, but more yellowish-grey; on the forewing the transverse lines end at the inner margin without distinct white spots. Abdomen very bright black and red. — f. **geneforti** *Bouv.* (117 D d), likewise from Ecuador, shows more yellowish-grey forewings, the transverse *geneforti*. lines well marked at the costal margin, badly marked at the inner margin. Body, legs, palpi, and base of hindwing pink, the ventrum greyish-black in the ♂, yellowish in the ♀. Another form from Guatemala is named — **angrandi** *Bouv.*; here the wings are smoky yellowish-brown, rarely feebly pink, the male antennae dark smoky *angrandi*. grey; I find that these forms evidently established on single specimens are more or less transitions, if we look at large series, and that they are not bound to localities.

Ph. coprea *sp. n.* (117 D e), however, although its exterior differs but little from *semirosea*, is a distinct *coprea*. species according to the different structure of the copulation organs. Larger and more slender, not variable, apex of forewing more obtusely rounded. Antennae somewhat lighter whitish yellow. Ground-colour monotonously dull yellowish-grey, thinly scaled, with hardly darker veins; it almost entirely lacks the conspicuous darker contrasting shades in the median area and the costal margin of *semirosea*, only the scarcely darker smoke-brown subterminal shadowy band is visible, but almost everywhere equally broad, between 4 and 6 scarcely narrower and without the strong notched distal border of *semirosea*. The white-spotted transverse lines are likewise the same, at the costal and inner margins widened into strong spots of a more creamy white colour, both between the veins distinctly orange-spotted. Hindwing dull like the forewing, 2 shadowy bands

little visible and without any notches. Body as in *semitrosea*, but the anus more rusty red, not carmine. According to 3 couples from Cuernavaca (Mexico). Types in the Coll. DRAUDT. On removing the anal hair the two ventrally bent black chitinized uncus-clasps are visible, at their base dorsally 2 feebly rounded transverse swellings, in *semitrosea* 2 distally extended coniform points.

fumosa. **Ph. fumosa** Fldr. (117 D e) is similar to *semitrosea*, but deep sooty black, the subterminal area on both wings usually brightened, the subterminal shadowy band often very feeble, before the olive yellow fringe a thick black marginal line; the two transverse lines also shaped as in *semitrosea*, but much nearer together and mostly reduced to tiny vein-dots excepting the large yellowish-white costal-marginal and inner-marginal spots; the portions situate between the veins are reddish olive-yellow. A very variable species; a much blacker form *inornata*. without the transverse lines, only with 2 white costal-marginal spots is named: — **inornata** Bouv. (117 D d), but also here all kinds of transitions occur. Mexico.

citrina. **Ph. citrina** Drc. (117 D e) entirely resembles the preceding species on the smoky yellowish-grey forewing in the marking of the transverse lines being composed of white costal-marginal spots and vein-dots, but the hindwing is unicoloured yellowish orange in the ♂, yellowish smoky grey like the forewing in the ♀. Thorax also more yellowish, abdomen with pink rings. The ♂ antennae are very dark brown. Venezuela and Guatemala.

orva. **Ph. orva** Weym. was not before me. Abdominal rings not red but chrome-coloured, only the anus rosy red. Wings olive brown, at the costal margin with 2 chrome-coloured spots at $\frac{1}{3}$ and $\frac{2}{3}$ of its length, below them rows of yellow vein-dots; subterminal line indicated by whitish dusting distally to it, traversed by dark brown veins and internerval lines; fringe yellow. Hindwing with a whitish submarginal band, only traversed by dark veins. Described from a ♂ from Colombia.

antonia. **Ph. antonia** Dogn. (117 D e). Above black, subterminally and at the margin lighter greyish, with 2 lines of dots being yellow in the ♂, white in the ♀, the antemedian line composed of 3 dots, the postmedian line of a row of vein-dots, somewhat distally angled on 5 and 6, and ending on 1 near the interior line. On the hindwing the 2nd line consists in the ♂ of but 2 dots, in the ♀ of several. Body black, metathorax, anus, tarsi, and base of hindwing beneath with pink hair. Colombia.

nigra. **Ph. nigra** Dogn. was not before me. Size and shape of *fumosa*. Upper surface of the 4 wings smoky black, forewing with 2 straight transverse lines little contrasting with the ground-colour and somewhat convergent towards the inner margin; between them a cellular dot. Hindwing with a discal dot and a likewise inconspicuous rounded postmedian line. Body black, the abdomen above with yellow rings. Antennae dark yellow. Expanse of wings: 65 mm. Paramba (Ecuador), described from a ♂.

flavilinea. **Ph. flavilinea** sp. n. (118 a) is very different. Wings brownish-pink with fine darker veins, basal area dusted with smoke-brown; both the transverse lines almost straight, broad, dull yellow, the anterior one distally shaded with a faded brown, the posterior one inside bordered by a distinct narrow line, outside by a brown broad faded shade; discal dot absent, subterminal line very feebly marked, in the upper half more conspicuous by a brownish subapical marginal shade. Head, collar, abdomen and legs brownish-pink, palpi and thorax brown. Type: 1 ♂ from Muzo (Colombia; Fassl leg.) e Coll. BANG-HAAS.

manes. **Ph. manes** Drc. (130 A b). According to the kind information by Mr. TALBOT 6 and 7 of the forewing are stalked in the type, nevertheless I range the species here owing to the exterior resembling the *semitrosea*-type, because it fits nowhere else, the least beside *araucaria* where it would have to be ranged. Anterior body blackish-brown, abdomen bluish-black, anus rusty red. Forewing brown, basally blackened, with a longish black discal spot, an almost straight black postmedian line before which there is a white triangle at the costal margin and a notched subterminal line behind it; between 4 and 5, and 6 and 7 subterminal blackish shading. Hindwing the same, but basally pinkish-red; the space between the two lines darkened black, before it at the costal margin likewise a white triangle. Mexico (Orizaba).

20. Genus: **Phidira** gen. nov.

Very closely allied to the preceding genus and only separated by the stalked veins 6 and 7 of the forewing. Only 1 species characterized by an entirely different scheme of markings, which has evidently developed from that of the *triangulum*-group, the costal base of the triangular spot extending almost from the base to the apex.

araucariae. **Ph. araucariae** Jones (= *divisa* Jord.) (118 a). Thorax blackish-brown, abdomen orange-brown, with black bands. Forewing coffee-brown with a white line beginning about 6 mm before the apex, extending obliquely inwards to about the first third of vein 2 and from here in a slightly costal bow to the base of the costal margin; this line is bordered with black towards the costal margin, which colour gradually warms upwards into the brown colour and is united with a thick black discal streak; from the base of the inner margin

another white line extends in a slight S-curve and upwards convex bow to 1 cm before the anal angle; subterminal band blackish-brown, with 2 bows towards the margin between 2 and 4. Hindwing lighter, at the base with somewhat brownish ochreous hair, with a large very indistinct discal spot and a light submarginal line which is bordered with dark on both sides. Brazil (Parana; Minas Geraes).

21. Genus: **Mesoleuca** Pack.

Some few evidently closely allied species at once discernible by the long-stalked course and mostly also contrasting colour of veins 5 and 6 of the hindwing; on the forewing 6 and 7 are also distinctly stalked. Mostly thinly scaled, rather small insects of a characteristic exterior. The ♀♀ seem to be without wings.

Type: *M. venosa* Wkr.

M. venosa Wkr. (118 a). Wings whitish, with fine black veins and fringes, and a smoky brownish narrow *venosa*. subterminal line parallel to the margin on both wings. — Body black, collar yellowish-grey, ventrum and sides with orange rings, anus copper-red or black. — **nigra** Dogn. (118 a) is scaled smoky blackish excepting the *nigra*. light cell-end. DOGNIN describes a ♀ belonging to it to be quite black and without wings. Colombia (Bogota; Sabatoga).

D. famula Maass. (118 a) is smaller scaled blackish on the olive-yellow ground, at the costal and distal *famula*. margins and on the hindwing more densely scaled, with black veins, a yellow angular spot at the cell-end and a yellow submarginal line; the yellow fringe is speckled with black. Abdomen with yellow and black rings, anus red. Ecuador.

D. nata Maass. is very similar to *famula*, browner, more densely scaled and less transparent, the yellow *nata*. postmedian line more remote from the margin and inwards bordered with a darker brown, only the forewing with black veins, hindwing brown with ochreous fringe. Ecuador.

22. Genus: **Kentroleuca** gen. n.

Only 1 species originally described as *Heliconisa*, with broad wings, an almost Geometrid-like habitus and a slim body. On both wings veins 6 and 7 most characteristically stalked; lower cell-angle far produced especially on the hindwing. Palpi short with a very small terminal joint. Anterior tibiae at the end inside with a very strong slightly bent horny sting of $\frac{1}{3}$ the length of the tarsus, and outside a short one; hind tibiae with a pair of short terminal spurs.

O. lineosa Wkr. (118 b). Front body yellowish grey, abdomen above ochreous, beneath white. Antennae *lineosa*. brown. Forewing smoky blackish, with fine yellowish ochreous veins on both sides bordered with whitish, and a creamy white discal and submedian fold, the base of the wing between the light veins distally obliquely cut off black; a white slightly oblique subterminal line which projects distally somewhat arcuately between the veins and is darker edged towards the inner margin. Hindwing the same, the line less distinct and bent parallel to the margin. Fringe white. Brazil, apparently very rare.

23. Genus: **Hirpida** gen. n.

Like the preceding genus of a somewhat Geometrid-like habitus, apex of forewing slightly falciform. Palpi shorter than in *Kentroleuca*, antennae of ♂ with short pectinations. Neuration quite the same as in *Kentroleuca*; the horny sting of the anterior tibia is absent.

Type: *H. gaujoni* Dogn.

H. gaujoni Dogn. (= choba Drc., ♀-nigrolinea Drc.) (118 b). Body and forewing light red-brown, base *gaujoni*. and marginal area with a cinnamon pink hue and dusted with lilac white, with 2 transverse lines, the posterior one distinctly and regularly notched, between them a black discal dot and behind it a straight broad shadowy band; between the notched line and the margin some interrupted parts of a lilac grey subterminal line. Hindwing with an indistinct straight postmedian line, at the anal angle dusted with lilac grey. Beneath with 2 straight lines behind the discal dot. Ecuador; Bolivia; Peru.

H. rubella Dogn. (118 b), described as *Saturnia*, is very closely allied to *gaujoni*, distinguished by the *rubella*. more purple pink ground-colour; discal dot and median shadow as in *gaujoni*, but instead of the regularly dentate postmedian line there is here an irregular hazy double shadowy line. Ecuador.

24. Genus: **Heliconisa** Wkr.

It contains but one species very closely allied, on the whole, to the genus *Dirphia* from which it is chiefly distinguished by a very conspicuous sexual dimorphism. ♂ with a slender body, long bipectinated antennae and broad wings, whereas the ♀ is of a very clumsy structure with very feebly crenated antennae and narrow, incompletely developed wings. Neuration as in *Dirphia*, on the forewing 6 and 7 arise from the same place, or occasionally also on a short stalk. On both wings the cells are long with a strongly produced lower angle. Tibial epiphysis of $\frac{3}{4}$ the length of the tibia, thicker than the tibia itself and sacciform.

*pagen-
stecheri.*

H. pagenstecheri Geyer (= impar Wkr., castora H. S., lancea Btlr.) (118 b, c). ♂ freshly emerged scantily strewn with black hair-scales which are at once shed in flying, with ochreous veins, a horseshoe-like black marking at the cell-end and a black margin crossed by the yellow veins. Hindwing the same, but only with a small discal spot. Body yellowish-grey. ♀ with more reddish ochreous veins and between the veins more densely scaled black. Body above black, beneath deep reddish ochreous, above with similar rings and hair. Southern Brazil; Paraguay; Argentina. ZIKAN observed the ♂♂ flying between 9 a. m. and 3 p. m.: the ♀ drops her eggs in lumps into the grass forming the food of the blackish-brown, black-spined larva with a red-brown head. The metamorphosis into a chestnut-red pupa takes place in a loose web on the ground between tufts of grass.

25. Genus: **Ithomisa** Obth.

Very similar to the preceding genus, but separated by shorter cells of the wings, the lower angle of which is not so far produced. On the forewing 6 and 7 arise almost invariably separated; especially the hindwing is much broader with a rounder margin. The epiphysis on the anterior tibia is longer and attains entirely or almost the length of the tibia. Body of a stronger build, the ♀ with completely developed wings.

Type: *kinkelini* Oberth.

kinkelini.

I. kinkelini Oberth. (118 c). Variable; body varying between a whitish yellowish-grey and blackish-brown; forewing in the basal half like the body, from yellowish-grey to red-brown, without a discal spot, in the distal half hyaline; the veins are coloured like the basal half, turning black distally and ending thickened in the variably broad black marginal area. Hindwing the same. The ♀ described by BERG is very much like that of the following species, but rays of the Isabel-coloured ground-colour remain between the broadly blackened veins without reaching the black margin. Argentina.

catherina.

I. catherina Schs. (= caina Zikan nec Ky.) (118 c, 119 b). Likewise a most variable species; body from greyish-brown to blackish-brown, anus more or less rusty red. Colour of wings varying between ivory white and yellowish-brown, in the basal portion mostly more red-brown, with thick black veins terminating like broad rays into the broad black margin; black discal spots may be present in both wings, or absent; the latter form

impuncta.

mostly comprising the light specimens may be named: — **impuncta** f. n. The ♀ is very much like the ♀ of *Eudytaria venata*, but it is larger with more pointed wings and between the veins there are always narrow more reddish rays visible terminating into the darkened margin. The egg which is light blue at first and then white, is deposited on *Paepalanthus polyanthus*. The larva with a habitus exactly like that of *Automeris* is green or black with branched thorns and pupates between leaves or in the grass without a web, the pupa being clumsy and dark red-brown. Southern Brazil.

carilapha.

I. carilapha Schs., founded upon but one female with an expanse of 132 mm, is very similar to some ♂♂ of *E. venata*, and I am not sure whether it belongs to the genus *Eudytaria* or to this genus. Palpi black, body blackish-brown, with reddish-ochreous hair. Wings cinnamon-brown, in the distal half irregularly strewn with short brownish-black striae, fringes brownish-black; forewing with thick black veins, at the cross-vein an oblique white line, in the lower half proximad bordered with black. Hindwing in the cell and below it as far as the centre of the wing with reddish-brown hair, with fine black veins, a large round black discal spot. Uruguay (Montevideo). It may be related to *D. zeta* Berg (cf. p. 769).

lepta.

I. lepta Drc. was not before me, and from the insufficient description it cannot be ascertained to which genus it belongs. Forewings and hindwing unicoloured dark brown, the darkest along the costal margin and apex of the forewing; veins somewhat darker. Under surface of forewing slightly dusted with grey. Body dark brown, antennae black. Expanse of wings: 5½ inches. Paraguay.

26. Genus: **Eudytaria** Btlr.

Very similar to *Ithomisa*, merely separated by the somewhat obtuser shape of the wings and the stouter abdomen, especially in the ♀. In both wings the cross-vein is less oblique, in the forewing 5 is somewhat nearer to 6. Only 1 species:

E. venata Btlr. (= consularis Burm., tribunalis Burm.) (119 a, b). ♂: the reddish flesh-coloured ground *venata* is speckled in variable intensity with blackish-brown longitudinal striae increasing towards the margin; veins distinctly black, the median vein being thickest; lower discocellular not marked. Hindwing the same, but only speckled in the marginal area, and only here with black veins; a more or less thick round black spot at the cell-end. Abdomen deep blackish brown with reddish hair. ♀: somewhat less intensely speckled. The black larva with green branched thorns lives on Eryngium. Argentina, Paraguay.

27. Genus: **Catharisa** Jord.

Proboscis composed of 2 feeble threads; palpi short, antennal shaft compressed, with long double pectinations, also in the ♀. Anterior tibiae with short apical thorns, posterior tibiae only with terminal spurs. Cross-vein less oblique than in *Heliconisa*. Neuration of hindwing as in *Heliconisa*, but with a broader cell and less oblique cross-vein. Only 1 species.

C. cerina Jord. (118 d). Unicoloured pale lemon-yellow, scantily scaled, margins and fringes somewhat *cerina*. more reddish. Forewing with a tiny discal spot showing through from beneath. Hindwing with a black, white-centred ocellus. Paraguay.

28. Genus: **Eubergia** Bouv.

Intermediary between *Automeris* and *Dirphia*; mostly small, rather variegated species with light veins, almost nearer to *Automeris*. Antennae bipectinate, palpi rather well developed. Neuration on the whole same as that of *Dirphia*, on the forewing 6 and 7 arise from the same base, on the hindwing separately, 5 very near to 6. The species are also somewhat similar to the following *Hemileucinae* by the very feeble discocellular; it extends less obliquely than in *Heliconisa*. Epiphysis of anterior tibiae represented by a thin formation encased in a cavity of the tibia, not projecting as in *Heliconisa*.

Type: *E. caisa* Berg.

E. caisa Berg (= caina Ky., radians Dogn.) (118 d) is a small species which is often mistaken. Thorax *caisa*. blackish, abdomen reddish brick-coloured. Costal margin and disc of forewing reddish-grey; veins varying between ochreous-red and brick-red, bordered with blackish on both sides, the ground of the wing between them creamy white, interrupted by 2 broad yellowish-white rather straight transverse bands extending almost vertically to the inner margin. Between them a large roundish oval discal macula with a black centre. Veins of hindwing only in the marginal half coloured like those on the forewing, the discal macula larger. Paraguay; Argentina.

E. boetifica Drc. (= bedoci Bouv.) (118 d) is very similar, but at once discernible by the much more *boetifica*. oblique course of the white transverse bands, the anterior one of which forms a very acute angle to the lower cell-angle above which the punctiform black discal spot is situate before a yellowish-white spot. Costal margin of forewing and disc of hindwing yellowish-white, not reddish-grey; thorax above also white and not blackish. It was not easy to trace the synonymy from the very insufficient description by DRUCE who does not even mention the transverse bands. Mr. TALBOT had the kindness to substantiate the diagnose from the type. Paraguay; Argentina; Southern Brazil; Peru.

E. argyrea Weym. (118 d), described as *Automeris*, appears to me a doubtful species, since it might be *argyrea*. merely a ♀ of *caisa* with a larger ocellus in the purer pink hindwing, which, in my opinion, is the only mark of distinction from the said species. Discal spot of hindwing larger here, a black ring filled with red. All the rest corresponds to *caisa*, though the somewhat narrower transverse bands are described to be silvery white. Sergipe, Southern Brazil.

E. strigosa M. & W. (118 d) is a somewhat larger species with more elongate wings. Ground-colour *strigosa*. whitish-yellow, margins more intensely ochreous than the veins of the marginal area, which are bordered with blackish-grey on both sides; a white parallel stripe besides before the margin; the cell and 2 longitudinal stripes behind it as well as a broad submedian stripe likewise blackish, finely longitudinally parted by light. Thorax blackish, patagia outside yellowish-white. Abdomen ochreous, with black rings. Brazil, exact habitat not stated. The type from the Berlin Museum was before me.

E. berthia Schs. (116 e). This wonderful species has a black thorax with yellow-edged patagia, a red *berthia*. abdomen which is brownish in the ♀. Forewing dark grey, with orange veins bordered with light yellow and yellowish cellular and submedian folds, with a dark red spot bordered with black at the cell-end. Hindwing of ♂ red, at the base with yellow hair, with a black margin interrupted by yellow veins, with a black ocellus centred brownish at the cell-end, with a white central streak. In the ♀ the hindwing is of a duller reddish colour warming into grey towards the margin. Castro, Parana.

2. Division: vein 1 b of hindwing present (*Hemileucinae*).

29. Genus: **Euleucophaeus** Pack.

This genus contains 1 dozen of medium-sized, rather scantily scaled lepidoptera distinguished by a certain sexual dimorphism. Nearly all are brownish-grey, more or less tinted pink, with 2 white transverse bands and a small frequently unscaled discal spot, a brownish-red abdomen, some species being difficult to separate. Like all the genuine *Hemileucidae* they have a vein 1 b, though it is very feeble; the cross-vein is extremely feeble in both wings, so that the cell is practically open. On the forewing 2, 3, and 4 arise at almost equal distances, 5 and 6 from the upper cell-angle, 7 and 8 and 10 rather close together from the anterior margin of the cell shortly before the cell-angle. On the hindwing 5 and 6 likewise arise from the upper cell-angle either together or close together, 7 a little before it. Antennae of ♂ bipectinate, in the ♀ serrate, partly with rather long ciliary bristles, so that they almost look short-combed. Thorax with very long hair. The larvae are exactly like those of *Saturnia*, cylindrical, with thorns ramified fir-like on tubercles. All of them probably live on grass; Prof. COCKERELL has ascertained that they may even do much harm to pastures. PACKARD considers this genus to be merely a section of *Hemileuca*, but owing to biological and some habitual differences from the latter we keep it up.

Type: *E. tricolor* Pack.

- rubridorsa*. **E. rubridorsa** Fldr. (120 a). The ♂ is brownish-grey with broad ochreous veins and costal margin, 2 whitish transverse bands, the exterior one of which is distinctly undulated; hindwing scarcely lighter, with a basal pink tint and very feeble traces of a postmedian shadowy band. The ♀ is but little larger. Mexico (City).
- norba*. — **norba** Drc. (120 a) is somewhat lighter, the costal margin of the forewing much narrower ochreous, hindwing paler, more extensively pink at the base, with a distinct darker postmedian shadowy band which is bordered with whitish outside. The ♀ is larger than that of *rubridorsa*, the yellow veins and white transverse lines much less prominent. Zacualpan, Amecameca. — **minette** Dyar is a somewhat smaller form, described according to a single ♂ from Mexico (habitat not certain); it surely belongs to this species and is said to be distinguished by a larger white, centrally unscaled discal spot on the forewing. Hindwing with a distinct white postmedian band.
- hualapai*. **E. hualapai** Neum. is an uncertain species described from a single ♀ from South-West Arizona: it must be closely allied to *mania* and has likewise an ochreous costal margin of the forewing, being distinguished by but one feeble postmedian transverse line, the anterior one being absent altogether. From Cuernavaca (Mexico), numbers of a species in both sexes are before me, which may be allied to *hualapai*, whilst the ♂ may also be allied to *lares*. In honour of Dr. DYAR in Washington, who was the first to search into the graminivorous species: — **dyari** sp. n. (120 a). The ♂ resembles *mania* and is somewhat smaller on an average, with rather straight, narrow and quite parallel white transverse lines, the exterior line proceeding relatively near the apex; median area very broad; hindwing whitish, basally very feebly pink, with a distinct grey postmedian and marginal band. Thorax greyish-white, abdomen bright brownish-red. The larger ♀ is very pale, both the fine white transverse lines obliterated. Types in the Coll. DRAUDT.
- lares*. **E. lares** Drc. is neither certain, described from a single ♂, from Durango City; it must be allied to the preceding species, but according to the figure it has much more sinuate and broader white transverse bands, a narrower median area and a dull yellow abdomen with pink hair only at the base.
- mania*. **E. mania** Drc. (120 b) is the largest species, of a most variable colouring, from brownish-grey to a pure pink (— **macellaria** f. n.) (120 b), with a narrow ochreous costal margin, broad white transverse bands and almost purely white hindwings. Eastern coast, State of Vera Cruz. My father found the larvae on various species of grass, also on maize, in December; they were light reddish-brown with blackish knobbed tubercles with star-hairs, the green pupae between threads in the grass yielding the imagines in February.
- numa*. **E. numa** Drc. (120 b) is a smaller, much darker, greyish-black species with quite dark hindwings; the median area enclosed by the white transverse lines is variably broad as in all the other species, the whitish discal spot either very near to the antemedian line or quite separate. Base of hindwing dark pink. The larger ♀ shows a duller colouring, the base of the hindwing is much more extensively pink. Mexico (City). — **nitria** Drc., the type of which is before me from the Coll. STGR. (Berlin Museum), is said to be somewhat larger, which however I find to be incorrect on comparing it with the series of *numa* lying before me. Base of hindwing without pink; I cannot find any other essential difference. The type is only labelled: Mexico, without any habitat stated.
- oliviae*. **E. oliviae** Ckll. (120 c) is very similar to *mania*, but it has no ochreous costal margin of the forewing and the ground-colour is much paler, so that the feeble white transverse bands being especially broad in the ♂ are rather indistinct. From New Mexico, in September and October. The larva described by COCKERELL is ochreous with darker brown markings, a dark brown head and black, fir-tree-like thorns, living on grass

(*Mühlenbeckia texana*) like those of the other species. — ab. *grisea* *Ckll.* shows the median area dusted with *grisea*, a much darker grey. — ab. *suffusa* *Ckll.*, described according to a ♀, is suffused with reddish-grey above, with *suffusa*, a blackish costal-marginal area.

E. sororius *H. Edw.* is much darker, the transverse lines therefore much more distinct and broadly *sororius*, white, the antemedian line straight; forewing with a yellowish-brown discal spot. This species which has remained unknown to me was described from a single ♀ from La Paz, Lower California, and does not seem to have been found again. In my opinion it may belong to *numa*; but the fringe of the hindwing is described to be white, whereas in *numa* it is blackish-grey.

E. mexicana *Drc.* (= *marillia* *Dyar*) (120 c), originally described as *Metanastria*, is likewise very similar *mexicana*, to *mania*, but darker and at once discernible by the costal margin of the forewing above not or scarcely being yellow; the median area edged by broad white transverse bands is mostly darker. Hindwing on an average somewhat darker than in *mania*, with a rather distinct postmedian band. The ♀ is generally intensely suffused with brownish-pink. Tehuacan (Puebla). I have been able to compare the types from the Berlin Museum, which are exactly the same as *marillia*. — *packardi* *Ckll.*, described from a ♀ from Tacubaya (Mexico), may belong *packardi*, to it, since the description is very similar excepting the somewhat darker pinkish-carmine colouring.

E. lex *Drc.* (120 c) has narrower wings with a more oblique distal margin of the forewing, for which *lex*, reason the transverse lines are also somewhat more oblique, the anterior one being acute-angular below the costal margin, the costal margin broadly white especially in the median area. Hindwing in the ♂ all white, in the ♀ with a grey hue, with a whitish subterminal band. Fringe very broadly white. Mexico (City), Durango City.

E. tricolor *Pack.* (120 d) is very similar to *lex*, with somewhat broader wings, the white colour of the *tricolor*, transverse lines much more extensive, so that only a relatively narrow, grey-strewn marginal area remains in the ♂; the white discal spot is distinct, edged with dark and often with a slight yellowish tint. Hindwing of ♂ white with a fine dark discal streak or ring, in the ♀ grey, basally and postmedianly broad whitish. From Southern Arizona, common in the Sa. Catalina Mts. in February till April.

30. Genus: **Hemileuca** *Wkr.*

This genus is very similar to the species of *Euleucophaeus*. The imagines have generally somewhat more elongated wings with a more oblique distal margin; mostly still more scantily scaled, the cross-veins on both wings stronger, and distinctly angled in the centre. On the hindwing veins 5 and 6 arise on a short stalk in some species. The antennae of the ♂♂ are somewhat shorter pectinated, with thicker dents, those of the ♀♀ likewise shortly pectinated, not serrated and bristly. The larvae, as far as they are known, contrary to those of the preceding genus, live on foliage-trees, especially on willows.

Type: *H. maia* *Dru.*

H. electra *Wright* (120 d). A most variable species; forewing black with 2 whitish basal stripes, a *electra*, whitish median band enclosing a black-ringed hyaline crescent, and light subterminal markings. Hindwing reddish brick-coloured with a black discal spot enclosing a light central streak, and a black marginal band. California and Sonora. — f. *clio* *B. & McD.* exhibits, beside the light median band, quite black forewings and *clio*, deeper red hindwings which are dusted with black distally. Arizona. — ab. *rickseckeri* *Wats.* is an intensely *rickseckeri*, blackened form, only with a discal spot and traces of the transverse lines at the inner margin.

H. maia *Dru.* (= *proserpina* *F.*) (120 d) is one of the commonest species, black, scantily scaled, with a *maia*, whitish rather narrow median band on both wings, enclosing a black central spot which bears a white narrow angled central streak. — ab. *lintneri* *Ckll.* has quite blackish, scantily scaled forewings without the whitish *lintneri*, transverse band, whilst it is present on the hindwing. Larva purple black, dotted yellow, with chestnut-brown abdominal and anal legs; it bears firtree-like black burning thorns and lives gregariously in spring on oaks, willows, cherry-trees and hazel. It pupates in the soil without a cocoon. The imago flies in the daytime in the latter part of autumn. Atlantic States, Colorado.

H. lucina *H. Edw.* is very much like *maia*, but somewhat smaller and much more sparsely scaled, with *lucina*, broader whitish median bands. Thorax quite black in distinction from the following species. New England. — ab. *obsoleta* *Reiff* exhibits on the forewing more or less extinct transverse bands; — ab. *lutea* *Reiff* is more *obsoleta*, grey, the transverse bands intensely tinted yellowish; both forms described from New Hampshire (Raymond). *lutea*. — subsp. *latifascia* *B. & McD.* is the race from Manitoba, with much broader median bands especially on the *latifascia*, forewing, so that only a narrow black marginal band remains as in *nevadensis*. Discal spot of hindwing shorter and almost extinct. Larva much more glossy black with a distinct white sublateral stripe; it lives gregariously in heaps on Spiraeac. It does not pupate in the soil, but between dry leaves.

- nevadensis*. **H. nevadensis** *Stretch*. (= *californica* *Wright*, *artemis* *Pack.*) (120 c) is very similar to the preceding species, especially *latifascia*, but more densely scaled than the latter and easily discernible by the thorax being covered with yellowish-white hair; the white median area of both wings very broad, the discal spot of the hindwing of a triangular shape without a white central streak. California, Rocky Mts. to the Pacific Coast. Larva sea-green or yellowish with black thorns and red-brown head and feet. It lives on willows and poplar-trees.
- juno*. **H. juno** *Pack.* (= *yavapai* *Pack.*) (120 e) is much more densely scaled, black, with a white median band divided by the black veins on the forewing and a small white discal spot; interior margin of tegulae and anal tuft of abdomen brick-red. Arizona and North Mexico. Larva velvety black, densely dotted yellowish-white, with orange transverse bands and an undulated yellowish-white lateral stripe.
- grotei*. **H. grotei** *G. & R.* (= *diana* *Pack.*) (120 e) is very similar to *juno*, but the median band of the forewing is mostly reduced to 3 white spots inclusive of the discal spot. Hindwing mostly only with one or two small apical spots, in the ♀ more with a narrow white median band. Texas and Colorado.
- neumoegeni*. **H. neumoegei** *H. Edw.* is a rare species with silvery white forewings with 2 black dentate transverse lines and reddish-orange discal spots edged with black, a similar one in the cell at the antemedian line. Arizona, California. Abdomen above with orange-red hair, antennae orange-brown. For this species and the following *burnsi* GROTE established the subgenus *Argyranthes*.
- burnsi*. **H. burnsi** *Wats.* (120 e) is a beautiful species very closely allied to *neumoegeni*, larger, snow-white with 2 black transverse bands, the exterior one being notched, with a black discal ring, the small orange antemedian spot is always absent, hindwing with a black discal spot or ring and a black transverse line behind it, which is thickened at the costal margin. Abdomen with black rings, basally reddish; without the orange-red hair
- paradoxa*. of *neumoegeni*. Mesothorax in front, palpi and forelegs pink, antennae deep dark brown. — **paradoxa** *Wats.* exhibits a less black abdomen; the colour of the wings is light reddish-yellow, not white, at the apex smoked lilac brown, more intensely marked, the costal margin between the two black bands lighter, the margin darkened
- itmac*. also on the hindwing. — ab. **ilmae** *Wats.* is yellowish-white on the body and wings, the black transverse bands
- nigrovenosa*. are broader and connected along the costal margin; described from a ♂. — ab. **nigrovenosa** *Wats.* shows the
- conjuncta*. veins of the forewing strewn with black scales; described from a ♀. — ab. **conjuncta** *Wats.* exhibits the black transverse bands connected by a black line at the inner margin, and black veins between the postmedian band and the discal spot. California.

31. Genus: **Pseudohazis** *Gr. & R.*

Separated from the preceding genus by the more elongated wings, the more produced apex of the forewing, larger more butterfly-like hindwings, and the somewhat slimmer body. In the other structure almost the same. The ♂♂ antennae are longer pectinated, those of the ♀♀ shorter pectinated. In the scheme of markings, the species are quite similar to those of the genus *Hemileuca*, they are most variable and fly in the forenoon in the sunshine, in a very lively and swift flight similar to that of the *Argynnis*-species flying with them. In the shape and colouring of the wings they also recall the Indo-Australian Geometrid genus *Dysphania*.

Type: *P. eglanterina* *Bsdv.*

- eglanterina*. **P. eglanterina** *Bsdv.* (= *eglanteriae* *H. S.*, *normalis* *Dyar*) (120 f) is an extremely variable species always recognisable by an orange longitudinal patch between the veins 4 and 5 behind the discal spot. The nomenclatural type is bone-coloured above, warming into orange towards the margin and suffused with pink, hindwing orange, with thick black transverse bands, on the forewing 2, on the hindwing one, and with large
- shastaensis*. black discal spots, that of the hindwing with a white central streak. — **shastaensis** *Behr.* is a form more intensely marked black, from the higher mountains; the whole ground is also blackened, so that extreme specimens
- denudata*. merely show a submarginal row of yellow or pink spots, and even those may be absent. — In **denudata** *Neum.* (= *boisduvalii* *Obth.*, *harrisi* *Obth.*) (120 f) the normal marking is very feebly marked blackish-grey like a shadow,
- nuttalli*. or entirely extinct. The type originates from California. — **nuttalli** *Stkr.* (= *uniformis* *Ckll.*), described according to a ♂ from Colorado at an altitude of 11 000 ft., is light yellowish ochreous above and beneath, with somewhat darker hindwings, the same markings as *eglanterina*, though without the yellow longitudinal patch behind the
- arizonensis*. discal spot. — **arizonensis** *Stkr.* has whitish-reddish flesh-coloured wings; from Arizona. — The larva of *eglanterina* is dull black with finely branched chestnut-brown fir-tree-like thorns, it lives on *Frangula californica* and roses. The larva of *shastaensis* has black thorns and lilac subdorsal, lateral and substigmatal longitudinal lines which may also disappear. It lives on *Ceanothus*, *Arctostaphylos*, also on cherries, gregariously until the last stage. It does not pupate in the soil.
- hera*. **P. hera** *Harris* (= *pica* *Wkr.*) (120 f). Light yellow, marked almost exactly like *H. neumoegei* or
- burnsi*, but with black wedges at the margin. Likewise most variable. Colorado, Utah, Nevada, New Mexico.
- marcata*. — **marcata** *Neum.* (120 f), from Oregon, is distinguished by a pure white ground-colour, the absence of the black wedge-shaped vein-ends on the hindwing, finer black transverse lines, and the absence of the black

basal marking on the hindwing. The larva resembles that of *eglanterina*, but inclusive of the thorns it is all black with an undulating whitish substigmatal line; it lives on *Salvia*.

32. Genus: **Coloradia** Blake.

In the structure likewise very near to the 3 preceding genera; second inner-marginal vein of the hindwing present, too. Shape of wings narrower, hindwing smaller. Antennae in the ♂ bipectinated, in the ♀ serrated. Cross-vein in both wings stronger and not angled; in both wings the origin of vein 5 is a little below the upper cell-angle, 6 and 7 arise from the same place or on a short stalk in both wings. The larvae of *pandora*, according to ALDRICH *), are considered a delicacy by the Mono Lake Indians who collect the larvae coming down from the trunks for the sake of pupation in July, by cutting ditches around the trees; the insects are then roasted in earth which has been made hot by fire, passed through a sieve, spread out on bark for 2 days, whereupon they are preserved cool and dry in bags and prepared for meals like "Irish Stew". ALDRICH found the tough "delicacy" to taste insipid and saltless, somewhat like linseed oil. The Indians call this food: Pe-aggie.

Type: *C. pandora* Blake.

C. pandora Blake (= *loiperda* Dyar) (120 g). Forewing strewn with black and white, hair-shaped *pandora* scales, with 2 notched black transverse lines which are more intensely bordered with white on the inverted sides especially at the costal margin; at the cross-vein a small black spot; the irregularly notched subterminal line is distally bordered with whitish; fringes speckled white on the ends of the veins. Hindwing whitish with a very feeble flesh-coloured tint, somewhat more distinct at the inner margin, with a black median spot, a notched postmedian line and a marginal band in which we notice a feebly lighter indistinct subterminal line. Larva on *Pinus jeffreyi*, at Lake Mono in altitudes of 7000 ft., biennial and pupating without a web in the soil; evolution in spring. Rocky Mts., from Montana to Mexico.

C. davisii B. & Benj. (120 g) is closely allied to *pandora* and similarly marked, smaller, more variegated, *davisii*. blacker, without any brownish tint, the subterminal line more conspicuous white. Hindwing and the under surface intensely tinted pink. White Mts., Arizona.

C. doris Barnes (= *lois* Dyar) (120 g) is much smaller than *pandora*, the wings are much less scaled, *doris*. more monotonously grey, particularly the ♀ dull brownish sooty grey; the subterminal line is scarcely scaled white distally. Hindwing in the ♂ almost hyaline whitish, only at the inner margin very feebly haired reddish, in the ♀ quite sooty grey. Colorado.

C. luski B. & Benj. bears the same relationship to *doris*, as *davisii* to *pandora*, blackish-grey, scantily *luski*. strewn white, with faded markings; hindwing intensely tinted pink like the whole under surface. Sexually dimorphous, in the ♀ the hindwing is much darker and more densely scaled than in the ♂. White Mts., Arizona. Expanse of wings: ♂ 57 mm, ♀ 60 mm.

C. lindseyi B. & Benj. is allied to *pandora* and may be regarded as its northern race; somewhat darker *lindseyi*. than *pandora*, the hindwing more pinkish; in the ♀ the forewing is much duller and more brownish, hindwing and under surface more suffused with reddish than in *pandora*. California, Oregon. Expanse of wings: ♂ 78—80 mm, ♀ 82—87 mm.

C. bonniwelli B. & Benj. is similarly marked as *pandora*, smaller, in the ♂ darker, more variegated, *bonniwelli*. rather like *davisii*, in the ♀ more softly scaled, more as in *doris*, but with more contrasting markings; hindwing and wings beneath as in *pandora*. New Mexico. Expanse: ♂ 64—70 mm, ♀ 75 mm. *

C. chiricahua B. & Benj. is still smaller, the ground of the wings more intensely strewn with white, *chiricahua*. the black transverse lines therefore more prominent, the subterminal line very distinctly white outside. Hindwing almost white, with a slight pink hue; without any brownish tinge. Under surface lighter than in *pandora* and without its brownish dingy colour. Expanse of wings: 60 mm. According to a ♂ from Arizona.

C. duffneri B. & Benj. is similar to *chiricahua*, larger, intensely strewn with white, particularly the *duffneri*. median area contrastingly white; transverse lines strong, subterminal line only marked by the distal white dusting; discal spot very small. Hindwing and under surface more intensely red. Expanse of wings: 67 mm. Cochise County, Arizona.

C. euphrosyne Dyar (120 g) is more brownish, the median area somewhat more prominently white, the *euphrosyne*. transverse lines broad, faded, scarcely notched, discal spot small. Hindwing variable, in the inner-marginal half dark pinkish earmine, marginal area more or less broadly blackish-grey, with a black discal spot which may be either isolated or also contained in the more or less broad brownish-grey median band. Mexico City.

*) Ann. Ent. Soc. Amer. XIV, No. 1, p. 36, 1921.

Appendix.

2. Genus: **Neopreptos** *n. gen.*

It was unfortunately only after the completion of the *Eupterotidae* that I had the occasion of examining the type of *clazomenia* having been described as "*Coloradia*", from the Berlin Museum e Coll. STAUDINGER, as well as a ♂ belonging to it from the Coll. BANG-HAAS. Both are genuine *Eupterotidae* and must be appended on p. 629 of this volume after *Preptos* to which genus they are closely allied. Palpi somewhat longer, drooping, antennae in the ♀ slightly longer combed than in *oropus*-♀, whilst the only ♂ that exists is without the antennae; the figure of *marathusa* in the Biologia shows them pectinated. Margin of forewing somewhat less oblique than in *Preptos*, neurulation of forewing almost the same, vein 5 removed down to the centre of the cross-vein, 6, 7 + 8, and 9 arise from the upper cell-angle. On the hindwing 5 arises far below the upper cell-angle, 6 + 7 on a very short stalk from the upper cell-angle; the bar between the first third of the anterior margin of the cell and the costal vein is very strong and distinct.

Type: *N. clazomenia* Drc.

clazomenia. **N. clazomenia** Drc. (86 f). Dark red-brown, sparsely intermixed with white hair-scales, with a subterminal transverse line of white hair-scales, bordered somewhat darker distally, behind it with spots of a feeble leaden gloss. Hindwing unicoloured. The larger ♀ is somewhat more sparsely scaled, the subterminal line much less distinct, the spots with the leaden gloss behind it somewhat more whitish especially at the costal margin, notchedly bordered outside. Panama (Chiriqui).

marathusa. **N. marathusa** Drc. I only know from the description in the Biologia. The ♂ e Coll. BANG-HAAS mentioned above corresponds well with the figure in the Biologia, but on the other hand I take it to be rather the ♂ of the species described as *clazomenia* as which we figure it. DRUCE describes *marathusa* from Costa Rica, the present specimen originates from the Chiriqui (Panama) like *clazomenia*, too. The ♀ of *marathusa* is described to be uniformly light brown, sparsely scaled, head and thorax dark brown, abdomen light yellowish-brown. It may be that DRUCE has confounded the two species, and his *marathusa*-♂ belongs as the other sex to *clazomenia* and not to *marathusa*-♀.

2. Subfamily: **Syssphingidae**.

This subfamily, also called *Ceratocampidae*, shows the following characters: a larger head than that of the *Saturnidae*, large globular eyes; proboscis absent or without function. Antennae bipectinated as far as half their length or to the ends. Body robust, more Sphingid-like than in the foregoing. Larvae mostly smooth in their last stage, without thorns, in the earlier stages with 2—6 thoracal horns and a double median abdominal horn.

1. Subordinate group: **Arsenurinae** Jord.

This group, the greatest part of which belongs to PACKARD'S *Agliinae*, differs from the genuine *Syssphingidae* in the broader shape of the wings and a less strong and shorter, sometimes almost slim abdomen. The forewing often exhibits a rounded falcate shape at the apex, now and then with notches and angles at the distal margin, the hindwing is frequently extended into a projection below the centre of the margin or a long tail. Palpi rather well developed, the ♂ antennae mostly shorter or longer pectinated to the ends, sometimes only serrated and ciliated. The larvae (see above) mostly pupate smoothly in the soil without a cocoon.

1. Genus: **Machaerosema** Rothsch.

It contains 6 large forms with a broad and remarkably high shape of the wings, the forewings with a falcate though well rounded apex. Abdomen, compared with the large wings, slim and small, not reaching to the centre of the inner margin in the ♂♂. Cell in both wings short and broad; in the forewing 3 arises shortly before the lower cell-angle, 5 above the centre of the cross-vein, 6 from the upper cell-angle. Antennae in both sexes pectinated. Formerly known as *Rhescyntis* Hbn.

Type: *M. hippodamia* Cr.

hippodamia. **M. hippodamia** Cr. (123 a) is the largest species with the broadest wings, of a more red-brown ground-colour, with a light median and marginal area; postmedian line mostly only double, sometimes treble; subterminal line reddish-yellow, behind it brown ornaments finely scaled bluish-grey, pierced by black fine vein-arrows.

pomposa. Guiana to Brazil. — **pomposa** f. n. (134 a) is a wonderful quite dark, deep olive brownish-black form without

any red-brown tints; the distal margin of the forewing being distally convex in the type is quite straight here, the distal margin of the hindwing being rounded in *hippodamia* is also rectilinear here and somewhat angled on 3 and 4; subterminal line olive, crossed by white on the veins of the hindwing, the ornaments behind it slate-coloured black, not brown. West Colombia (type in the Coll. NIEPELT).

M. mortii *Perty* (123 a, as "*martii*") is very near to *hippodamia*, smaller and more slender in general, *mortii*. not red-brown, but olive brown, the antemedian line more rounded, without the submedian dent, the postmedian line very distinctly fourfold, the median area often dusted with light grey. Brazil.

M. norax *Drc.* (123 b) is still more slender, with a more produced apex, distal margin more oblique, *norax*. apex of the wings not rounded between 6 and 8, but straightly cut off; ground-colour light fawn, median and basal areas darkened by dull olive brown; antemedian and postmedian lines confluent close below the cell. Distal margin of hindwing straight between 4 and 8, subterminal line correspondingly rectilinear obtusely angled, not bent, the ornaments behind it marked deep black in the upper section, below it only dull brown. Central America (Panama). Beside the type in the Berlin Museum figured by us I only know a second quite similar specimen from the Chiriqui e Coll. BANG-HAAS. — **guianensis** *Bouv.* (123 b) is smaller, wings shaped more *guianensis*. like those of *mortii*, subterminal line of hindwing also rounded as in *mortii*, the ornaments behind it quite absent, instead of them only the black vein-arrows are marked. Guiana, according to Mr. SCHAUSS also from Central America. The ♀ is smaller and more squatty, the fusion of the antemedian and postmedian lines already takes place in the cell, below it one has almost the impression as if the two lines were crossed; ground-colour olive brown, the subterminal lines broad and bright yellow, on the hindwing rounded.

M. hermes *Rothsch.* (123 b) has much narrower wings; above greyish-olive, the markings almost as in *hermes*. *hippodamia*, the antemedian double line and the postmedian line olive, feeble, the latter not accompanied by other lines; subterminal line greyish-olive, inside bordered with a deep olive brown, behind it large olive brown spots strewn with white. Hindwing round with a short inner margin, the ornaments behind the subterminal line light greenish-brown. British Guiana.

2. Genus: **Grammopelta** *Rothsch.*

Allied to the preceding genus, though its exterior appears to be very different and almost recalling a *Copaxa*. According to JORDAN, however, it is no *Agliina*, but a genuine *Arsenurina* with a large parasternum. Antennae dentate; forewing with a 4-branched subcostal vein, the 1st branch from the 2nd near the apex; 7 and 8 arise stalked with 6 from the upper cell-angle; the cell in both wings shows the lower angle extended in an acute angle. Hindwing rounded, the costal margin longer than the inner margin. Only 1 species is known hitherto:

G. lineata *Schs.* (= *cervina* *Rothsch.*, *convergens* *Bouv.*). Forewing light reddish-brown with darker *lineata*. veins, sparsely streaked darker, cross-vein and submedian vein likewise dark brown as well as 3 transverse lines: the first from the base of the costal margin to the centre of the inner margin, the 2nd right behind the middle, and a finer subterminal line being acute-angular subapically; apex dusted with white. Hindwing with but 2 transverse lines. French Guiana and South-Eastern Peru. — **nिएpeliti** *f. n.* (128 c) I call a larger and darker, *nिएpeliti*. more pinkish-brown form from Western Colombia, which is very intensely marked and in which the whole dark subterminal area prominently contrasts with the rest of the ground-colour. Type in the Coll. NIEPELT from which a magnificent couple was before me.

3. Genus: **Arsenura** *Dunc.*

It has the same neuration as the preceding genus, but the wings are narrower, the body is more robust, the abdomen projects beyond the centre of the inner margin and often the anal angle. The shape of the wings is variable; there are species with entirely rounded wings, with an extended apex, with a gnawed margin, with angles or tails on the hindwings etc. The main difference is exhibited in the antennae which are combed shorter or serrate-dentate with ciliary tufts in the ♂♂, and finely serrate-dentate or plainly ciliated in the ♀♀. A great number of species have been described, the separation of which is partly difficult. In addition, the exterior of the species often varies considerably at different habitats. The greatest uncertainties are offered by the *armida*-group which ought to be thoroughly examined. We must confine ourselves here to enumerating what is hitherto known and inserting some conspicuous forms for the present as subordinate forms; only by careful examinations of the genital organs it will be possible to ascertain to which species they really belong.

Type: *A. syllia* *Cr.*

A. hercules *Wkr.* (124 a) is one of the largest and most beautiful species, light brown with a broad *hercules*. blackish-brown postmedian band extending at the inner margin to the base and not being distinctly defined inwards, outside by the light, then finely darker subterminal line, behind which there are large slate-blue or

violettish-blue spots; apical spot bilobate. Guiana to Brazil. The specimen figured e Coll. NIEPELT, from Western Colombia, is remarkably dark and variegated.

sylla. **A. sylla** Cr. is extraordinarily near to *hercules*; the shape of the wings is rounder, the apex less produced, the hindwing more rounded, without the concave indenture below the apex; darker brown, the discal ring finer, absent altogether on the hindwing; subterminal line broader, more creamy, the slate-blue spots behind it narrower; the black spot below the red-edged apical spot is much smaller. From Guiana (Surinam). — f.

pelias. **pelias** Jord. is lighter, the ♀ coloured almost like *meander*; the reddish-yellow subterminal line is still broader, the brown marginal area likewise broader, as broad as in *hercules*, the black spot below the apex as large as in *hercules*. Matto Grosso (Cuyaba).

alcemene. **A. alcemene** sp. n. (124 a) is smaller, darker chocolate brown, the postmedian band bordered inside in the lower half by the antemedian line which is rectangularly flawed on the median; subterminal line scarcely lighter than the brown ground, forming a uniform bow in the middle, projecting rectangularly on the inner-marginal vein. Hindwing rounded, costal margin much longer than the inner margin. Also very similar to *xanthopus*. According to 2 ♀♀ from Novo Friburgo, type in the Berlin Museum.

xanthopus. **A. xanthopus** Wkr. (124 b) is smaller than the preceding species, the ground of the wings lighter, the subterminal line forming a hardly noticeable angle in the large bow on 3 is very contrastingly brownish-white, whilst in *alcemene* it is not or scarcely lighter than the ground; behind it, on the hindwing, follows a lilac grey band of spots, behind it a band of red-brown spots, both separated by finely strewn bluish-white scales. Distributed in Brazil and Argentina. In the Berlin Museum there is a very light bone-white specimen intensely strewn with brown, from Parana. — **d'orbignyana** Bouv. is a transition-form to the following species. Forewing as in *xanthopus*, hindwing coloured like that of *angulatus*. Bolivia. Larva dark grey speckled with brown, with a yellow lateral line and a black and yellow neck-shield and anal end; young larva with 2 filiform horns on the 2nd ring and a similar one on the penultimate ring of half the length of the body, adult larva without horns. It lives on "racapicho": *Urena sinuata*, a shrub with burry fruits.

angulatus. **A. angulatus** Bouv. (124 b) is still smaller, more delicate and variegated, the ♂ antennae decidedly longer combed; the lilac apical spot is one-pointed, not bilobate as in the preceding species, the subterminal line on the hindwing much more notched, especially angular on 3 and 4. Brazil; apparently a common species.

meander. **A. meander** Wkr. (124 b) is a large reddish loam-coloured species, the ♀ being almost reddish brick-coloured, the wings not strewn at all; behind the yellowish-white subterminal which is especially broad on the hindwing there are red-brown, black-centred ornaments bordered by thick high black bows; below the apical spot which is suffused with pinkish-red there are 2 thick black spots. An apparently very rare species from Brazil. In the Berlin Museum there is a beautiful couple.

pandora. **A. pandora** Klug (124 c) is allied to *meander*, smaller, lighter, without the reddish brick-tinge, very intensely strewn with blackish-brown, otherwise very similarly marked, though the antemedian line of the forewing is only present in the lower half. Brazil (Minas Geraes).

cymonia. **A. cymonia** Roths. (125 c) differs from the *armida*-group in the darker coffee-brown ground-colour and a thick oval discal ring; the postmedian band is narrow, the subterminal line whiter, the black ornamental bows or sagittate spots distally scaled bluish-white. ♂ with a feeble tail as in *armida*. Peru.

polyodonta. **A. polyodonta** Jord. (124 c, 125 a) to a certain degree forms the transition from *pandora* to the following *armida*-group. Somewhat smaller than *pandora*, relatively sparsely scaled, the apex of the forewing slightly produced; the antemedian line is removed near to the discal spot and connected with it by a dent on the median vein, often forming an entire ring; postmedian band very dark, the subterminal line behind it very broad, purely white, with very strong, long black notches behind it. Only known from Mexico (Cuernavaca, Jalisco, Guerrero, Zacualpan). West-Mexican specimens are strewn with a darker greyish-black.

cassandra. **A. cassandra** Cr. (134 b) is a questionable species; judging from a ♀ kindly handed by Mr. BANG-HAAS and corresponding well with CRAMER'S figure, it is to be separated from *armida*. Of a yellowish tinge, sparsely scaled, like *polyodonta*; base, cell and the part of the median area as far as the postmedian line and below as far as vein 2 intensely strewn white; the marginal area is remarkably darker than the preceding subterminal band which ends taperingly at the inner margin in both wings. Larva, according to CRAMER, yellow with many black streak-markings and spots with an orange head, ventral and anal feet, the young larva in front with 4 horns, behind with one black thin horn. Guiana and Colombia (Muzo).

armida. **A. armida** Cr. (124 c, 125 a) is very similar, greyer; more densely scaled, the broad subterminal band darker brown than the somewhat more reddish marginal area, the subterminal line situate behind it is purely white only above the inner margin, in *cassandra* uniformly white almost in its whole extent. The ♂♂ are mostly

more monotonous and greyer than the lighter and more contrasting ♀♀. The larva is quite black, or with dark grey and black rings, the head and feet are reddish-yellow. It lives on Anona, Bombax, and other trees, often in great numbers. It pupates without a cocoon 6 inches deep in the soil. Widely distributed from Mexico to Southern Brazil. — **erythrinae** Fabr. (134 b) apparently refers to a tiny form showing a somewhat more produced apex of the forewing, of a much more monotonous and greyer colouring, the whitish subterminal line being quite absent except a whitish brightening above the interior angle. Chiefly from Eastern Colombia (Medina) and North-West Brazil. — **ciocolatina** f. n. (134 b) I denominate an interesting form or probably distinct species from Villavicencio (Eastern Colombia), of which 2 ♀♀ and 1 ♂ are before me from the Coll. BANG-HAAS. The light brown ground shows a very slight claret-coloured tint, with an indistinct broad antemedian line, the postmedian band brightly contrasting, of a very deep chocolate brown, inwardly not distinctly defined by a dark line as in the other forms, but indistinct; the subterminal line behind it is neither lighter, only its exterior edge is darker blackish-brown, but likewise indistinct, broad and faded, with a triangular white spot above the interior angle. On the under surface hazily defined dark brown postmedian bands, behind them very hazy brownish-white very broad subterminal lines. Another ♂ from the Rio Songo, in the Berlin Museum, is quite similar. — **archianassa** f. n. (125 b) is another, particularly large form from Western Colombia (e Coll. NIEPELT) in which, as in the following *rebeli*, the postmedian portion of the costal margin increases in brightness so that the deep chestnut brown postmedian band is particularly distinct; subterminal line in its whole extent intermixed with blue-white scales; marginal area likewise very dark.

A. albopicta Jord. The postmedian band of the forewing contrasts very little with the proximal portion of the wing and is but little darker than the umber-brown marginal band which does not exhibit the light tan-coloured tint of *armida*; in both wings a conspicuous white spot before the posterior angle, being triangular in the forewing; distal margin more oblique than in *armida*, posterior angle obtuser, the wing narrower for this reason. The white anal spot on the forewing beneath is large, distally produced on the submedian fold. Fonteboa (Upper Amazons).

A. rebeli Gschw. (= *oweni* Schs.) (125 c) has more elongated wings than *armida*, with an intensely whitish costal-marginal portion, below it the wing is of a soft grey colour, the costal-marginal portion of the hindwing is broadly whitish. Neuration different from *armida*, since vein 3 of forewing arises almost midway between 2 and 4, whilst in *armida* much nearer to 4. The ♀♀ often attain an extraordinary size, with an expanse of more than 20 cm. Ecuador.

A. mossi Jord. (125 a) is a similar species with extraordinarily elongated wings, the apex of the forewing being strongly produced, the hindwing forming a long tail. The ground-colour is a monotonous warm brownish grey, the equally coloured subterminal line is expanded into large white spots above the interior angle in both wings. Para. Two fine couples from Itaituba, e Coll. STGR., in the Berlin Museum.

A. aspasia H.-Sch. (126 a) is a very large species, almost intermediary between *rebeli* and *sylla*. Dark brown, base and median costal portion light grey; postmedian area inside indistinctly outlined, outside strongly excurved, projecting distally again above the interior angle, with an extensive yellowish-white brightening behind it. Apex suffused with rosy red. Brazil. Larva grey, marked brown with 4 thoracal and one conical caudal horn; it lives on Melastomaceae.

A. biundulata Schs. (126 a) is very similar to *aspasia*, lighter, the postmedian area inwardly more distinctly outlined, outside with 2 dents projecting in the middle. On the hindwing the submarginal ornaments are more intensely scaled light blue.

A. thomsoni Schs. (127 a) differs considerably in the postmedian line being almost quite straight, bordered with white outside above the centre and above the interior angle, with large steel-grey spots behind it. Ground-colour light reddish-brown, base and costal-marginal half scaled grey. Hindwing shaped like that of *hercules*. British Guiana.

A. arcae Drc. (125 b). Greyish-brown, postmedian band especially in the ♀♀ more red-brown, subterminal line behind it spotted white on the veins; from the lower end of the discal streak a faded darker stripe extends obliquely to the base of the inner margin. Hindwing with a short caudal lobe, margin almost entire. Under surface brownish white, finely speckled with brown, with small darker median spots, a feebly darker more yellowish postmedian band and small blackish spots on either side of the veins in the submarginal area. Panama to Colombia.

A. drucei Schs. (125 c) is very similar to *arcae* above, darker, with somewhat narrower wings and a narrower chestnut-brown postmedian band; in *arcae* there is one small white spot each on veins 4 and 5, in *drucei* a larger white spot between these two veins; in *arcae* the subterminal line is followed by a double arcuate line of light blue scales, whilst *drucei* only shows a hazy blackish-brown arcuate line divided by a series of whitish scales. Hindwing very different, marked as in *armida*. There is only a flatly concave curve at the margin between the veins 5 and 7, whereas in *arcae* all the ends of the veins are slightly notched. Under surface

quite different, dark reddish-brown with black median spots, behind them a thick red-brown postmedian line being introangular on the submedian fold in both wings; before the darker red-brown margin there is a light indistinct undulate line bordered with dark proximally. From the Volcano of Chiriqui, Panama.

crenulata. **A. crenulata** Schs. (134 c) is likewise very similar to *arcaeii*, but the hindwings more notched and with longer tails, as in the following *batesii*. Ground-colour dull greyish-brown, lighter whitish towards the costal margin in the median area; postmedian line scarcely darker than the ground; at the cross-vein a light spot bordered with dark; subterminal line undulated with small white vein-spots and a larger triangular spot above the interior angle. Ecuador.

batesii. **A. batesii** Fldr. is very similar to the ♀ of *arcaeii*, with a deeper chestnut-red postmedian band, behind which there are white vein-spots and the subterminal line composed of double light blue arcuate lines. Forewing and hindwing more intensely notched, the tail bicuspid, above it between 2 notches a deep indenture between 6 and 7. Guiana.

ponderosa. **A. ponderosa** Rothsch. (127 a) likewise approaches *arcaeii* and is the largest species known, with a light yellowish-brown colouring, a very distinct submedian oblique line to the base of the inner margin, a conspicuous quadrangular Isabel-coloured spot between veins 4 and 5 behind the subterminal line which is only indistinctly double. Eastern Peru (Chuchuras). — **guyanensis** Rothsch., from British Guiana, exhibits finer lines in the basal half of the forewing, a distinctly double subterminal line, the postmedian band being situate before it is broader than the marginal area.

championi. **A. championi** Drc. initiates another group with a more produced apex of the forewing, with a deep indenture at the distal margin below it. Forewing lighter or darker reddish-brown, coarsely strewn with black; antemedian line double, interior line straight, exterior line almost rectangularly broken on the submedian fold, both united at the inner margin; the black discal spot oblong bean-shaped, rusty yellow in the middle; the darker brown postmedian band is strongly curved, outside bordered by a black undulate line; below the apex a dark marginal spot enclosing 3 still darker sagittal streaks. Hindwing with a short tail on vein 5. Central America, especially in Honduras and Panama. — **columbiana** Rothsch. (126 c) is of a more violettish-black ground-colour, less strewn, the distal third beneath more grey. West and East Colombia.

undilinea. **A. undilinea** Schs. is allied with *championi*, light grey strewn with brownish; the incurved antemedian line extends to the centre of the inner margin, with a straight light brown nebulous stripe behind it; a long curved yellowish-brown streak at the cell-end, finely bordered with brown, postmedian band light greyish-brown, otherwise as in *championi*; the subterminal line shows white vein-dots in both wings. Expanse of wings: 120 mm. Costa Rica.

richardsoni. **A. richardsoni** Drc. (126 b) is smaller than the preceding species, the ground of the wings very light, brownish white, strewn with coarse blackish-brown spots, the interior antemedian line not straight, but distally notched on the median, the shadow behind it more distinct and thicker only at the inner-marginal half; the brown postmedian band is undulately dentate on both sides and traversed by lighter veins; marginal area very light, the subapical dark spot narrow; hindwing the same, but darker. Mexico (Guerrero). — **mestiza** f. n. (126 b) which may be a distinct species is much larger and more robust, darker, much less strewn, the interior antemedian line quite straight, the discal spot very broadly margined with black, with a distal appendage; postmedian band very broad and dark, still more excurved in both wings; subapical spot much broader, the extreme marginal half contrasting very dark with the inner half. Mexico (Zacualpan) several couples; type in the Coll. DRAUDT. The shape of the freshly emerged larva is like that of an *Adelocephala*, the thorns on the 2nd ring bicuspid at the ends, on the third of more than half the length of the body; the food-plant being unknown, the larva could not be bred.

romulus. **A. romulus** M. & W. (126 c) has still longer wings with very strongly extended apices. Ground-colour light greyish brown, finely strewn darker. Scheme of markings similar to that of *championi*, antemedian line only single, postmedian band very convex, lighter towards the costal margin, subapical spot very broad, deep red-brown. Hindwing with a very large discal spot and a very dark blackish-brown postmedian band and a rounded margin. Brazil.

4. Genus: **Titaea** Hbn.

This genus based upon but one extremely rare species connects the *armida*-group of the preceding genus with *Dysdaemonia*. Structurally scarcely different, vein 5 of forewing arises from the centre of the cross-vein. Hindwing with a short tail.

orsinome. **T. orsinome** Hbn. (= *latifascia* Wkr.) (127 c). Forewing light cinnamon brown with a dark fine antemedian line (distally shaded dark), discal streak and postmedian band, the latter may be of the ground-colour or darker. Hindwing with a slaty blue basal spot and postmedian band which is likewise bordered with slaty blue distally especially towards the costal margin. By the kindness of the Berlin Museum we were enabled to figure a fine couple.

5. Genus: **Dysdaemonia** Hbn.

Easily recognizable by the hindwing showing longer tails in the ♂, shorter ones in the ♀. Forewing with a long extended apex below which a long angle follows on vein 6, below it the margin of the wing is mostly undulately dentate, rarely smoothly margined. In the ♂♂, veins 3 and 4 terminate into the tail which is spatulately widened at the end, whilst the ♀♀ mostly show only a short angle here. The genus is divided into 2 well separated groups, for the second of which the name *Paradaemonia* was proposed by BOUVIER. Here the hyaline spot being present in the first group is absent and the tail ends more pointedly, not spatulately widened. ♂ antennae serrately ciliated.

Sectio I: with hyaline spots and a spatulate tail (*Dysdaemonia* Hbn.).

Type: *boreas* Cr.

D. boreas Cr. (= *auster* Fldr., *aristor* Rothsch.) (128 b). A common species distributed from Mexico *boreas*. to Paraguay. Forewing brownish or bluish ash-grey with 3 blackish-brown transverse lines and 2 vitreous spots at the cell-end, which are spotted blackish-brown inwards. Hindwing with but one small round vitreous spot, behind it 3 transverse lines, the outermost being bluish-black and arcuately extending from the anal angle into the tail. Colouring and size most variable. From the Berlin Museum there are 2 ♀♀ before me with an ivory white ground-colour, from Novo Friburgo; other specimens exhibit a band-like, mostly reddish-brown darkening between the 2nd and 3rd transverse lines, and a distinct or indistinct, twice notched shadow may occur between the 1st and 2nd transverse lines. — **brasiliensis** Rothsch. differs — though not invariably — in the *brasiliensis* curved submarginal line being extinct towards the tail. Rio de Janeiro and more to the south. The full-grown larva with a strongly inflated 3rd ring has no thorns, it is green, often marked violet. It lives on *Bombax ceiba*.

D. fosteri Rothsch. (128 b) is very similarly marked, easily discernible by a large round, dark-edged *fosteri*. hyaline spot on the hindwing. In the nomenclatural type the ground-colour is reddish-yellow, with olive green lines and bands. An extremely variable species, particularly the ground-colour may vary from a silvery or ashy grey (— **jordani** Giac.) through all kinds of brownish tints (— **cortesi** Giac.) to a pure green (— **viridis** *jordani*. *corlesi*. *viridis*. *fasciata*. K. John) (128 b); darkenings may occur between the two antemedian lines and between the postmedian and subterminal lines, so that sometimes very dark bands may be present (— forms of **fasciata** K. John) (128 c). The vitreous spots on the forewing may be very large, and there may be three of them. Larva green, in its youth with red-brown, white-curved thorns, adult with a white lateral stripe above which, on the 6th and 9th rings, there are white, red-spotted spots; the 4th ring is strongly raised, as in the larva of *Agria tau*. It lives on *Sama* and *Chorisia speciosa*.

D. tamerlan M. & W. (128 a) is a large species, light reddish-brown with indistinct transverse lines and *tamerlan*. bands, similar to *boreas*; the two exterior transverse lines close together at the inner margin, behind them greenish spots, bordered with whitish, in the lower half; a large greenish brown trapezoid spot before the apex at the costal margin, 2 small hyaline spots at the cell-end, inside connected by a dark strigiform spot. The ♀ is mostly more distinctly marked. Guiana to Southern Brazil. A very distinctly marked form, from Western Colombia (Bella Vista), e Coll. NIEBELT, exhibits exactly the same ashy grey colouring as *boreas*, with green-tinted lines and bands: — **columbiana** f. n. *columbiana*.

D. lemoulti Schs. shows a more notched margin than *tamerlan*. Ground-colour greyish-brown with a *lemoulti*. green tint, the markings as in *tamerlan* except the distal transverse lines which are more undulated and mostly show but one small hyaline spot at the cell-end, behind which there is a large irregular velvety brown spot; the dark subapical spot at the costal margin is triangular. French Guiana; Western Colombia.

D. nobilis Schs. (128 a) is likewise very similar, very large, with a very much produced apex, and the *nobilis*. distal margin still more notched, greenish-grey, the transverse lines and shadows darker grey, a large round hyaline spot at the cell-end and a very small one above it, with deep brown spots behind it. Postmedian shadow green; submarginal spots deep green bordered by white strewing. Costa Rica.

D. timur Weym. is easily separated from all the preceding species by the brightly contrasting dark *timur*. submarginal band in both wings; antemedian band of forewing shaped as in *tamerlan*; at the cell-end only a small hyaline spot in a long dark strigiform spot which projects distally somewhat like a tooth. Colombia (Villavicencio).

Sectio II: without hyaline spots, with a more pointed tail: *Paradaemonia* Bouv.

Type: *pluto* Westw.

D. pluto Westw. (= *kadenii* H.-Schäff., *glauescens* Wkr.) (127 b). This group has led to a considerable *pluto*. confusion of the synonymy. According to the kind information by Dr. JORDAN who compared the types, all the three names belong to one and the same species from South-Eastern Brazil, the statement of the patria

being Venezuela is due to a mistake. Forewing purple red-brown, dusted with violettish-white, the transverse bands not dusted, two each before and behind the long narrow discal streak, then follows a fine bluish-black line extending from the last third of the costal margin to the last third of the inner margin, i. e. from here from the margin parallel to about midway between veins 3 and 4 and as far as this place double and filled with bluish-white, then inwards in an obtuse angle and widened and turning brown towards the costal margin; the distal portion is still more widened and divergent almost in the original direction. Hindwing in the basal two thirds blackish-grey, separated from the red-brown marginal portion by a rectangularly flawed violet whitish band. The ♀ is mostly much brighter brown. — In **gravis** *Jordan* the bands of the forewing are straighter than in South-Brasilians; beneath without a red-brown marginal band on the forewing, the hindwing unicoloured brownish greyish-black with a small reddish-brown apical macula. French Guiana. — **andensis** *Rothsch.* has a more rounded margin of the forewing, a broader marginal area, a straighter double line; the narrower post-median band touches the cell-end. The upper portion of the white band on the hindwing is much nearer to the margin, the black band is twice as broad as in *pluto*. South-Eastern Peru.

mayi. **D. mayi** *Jord.* (= *pluto* auct. nec *Westw.*) (127 c) is a very similar species, mostly somewhat larger and darker, more blackish, easily discernible by the black double line reaching the inner margin in the middle or even before it; the darker transverse bands are narrower and straight as in *gravis*. Rio de Janeiro.

orsilochus. **D. orsilochus** (*Bsdv. i. l.*) *Maass.* (130 A b). According to the kind information by *JORDAN* this name was published by *MAASSEN* below the figure which was to represent *pluto* *Westw.* The figure, however, is not *pluto* but another species which must therefore bear the name placed below it, because this name refers to the bad figure being better reproduced by *PLÖRTZ*, the original of which we are able to figure. Ground-colour darker than in *pluto*, the double line straight as far as up to vein 6, then the interior portion vanishes, the exterior portion extends widened, shadow-like in the same direction to the costal margin, ending at the inner margin almost exactly in the middle as in *mayi*; the dark bands enclosing the median area are dark purple brown and altogether fill up the lower half of the median area, the innermost line becomes very feeble towards the costal margin and bends towards the base below vein 1. Hindwing light sandy grey in the basal half, then follows a broad purple brown transverse band separated by sandy brownish colour from the broad violettish-white transverse band which is slightly angled, then follows again a purple brown transverse band being very narrow at the costal and inner margins; two rusty yellow large spots at the apex and below it. Brazil.

platydesmia. **D. platydesmia** *Rothsch.* (= *d'espinaei* *Bouv.*) has the same shape as *pluto*, the black double line terminates at the inner margin at $\frac{2}{3}$, being also narrower and finer in the costal-marginal portion, more distinct than in the allies and less divergent; the angle of its bend being nearer to the inner margin than in *pluto*; instead of the distinct 4 transverse bands there are here but two though broader bands, the anterior one touching the inner margin almost rectangularly, the discal streak is not so isolated, but unites in front with the ante-median band. Hindwing as in *pluto*, fringe bright rusty red. Antennae more feebly pectinated than in the allies. In the nomenclatural form, from Peru and Colombia, the bands of the forewing are very dark chocolate, the white band of the hindwing very feeble towards the costa. — **castanea** *Rothsch.* (127 b) is larger, extensively suffused with chestnut brown, also beneath, the white band of the hindwing broad as far as the costal margin. Costa Rica.

nycteris. **D. nycteris** *Jord.* (127 b) has longer and narrower wings, the forewing is more produced at the apex than in all the other species with more indistinct brown bands, the spaces between them are more pale grey and darker streaked; discal spot elliptical, black, enclosing a light brown line. Hindwing with a long and narrow tail; both wings with a red-brown marginal line inwards bordered by a black line. Under surface pale grey, densely covered with purple black transverse striae, suffused with red-brown in and behind the cell. Venezuela.

thelia. **D. thelia** *Jord.* (= *wagneri* *Bouv.*). The male exhibits the more rounded wings of the ♀♀ of the other species, similar to *pluto*-♀, considerably smaller, the double line reaches the inner margin at $\frac{2}{3}$ as in *pluto*, both the lines being widened towards the costal margin, but the exterior line much narrower than in *pluto*; hindwings with shorter tails. Beneath unicoloured dingy brownish-grey, without transverse striae. From Paraguay and Argentina, also from Rio Grande do Sul.

samba. **D. samba** *Schs.* (134 c) is a smaller species, the margin of the forewing is straighter and more oblique; purple brown, dusted with violettish-white, with 2 rather straight transverse lines bordered with white inwards, the posterior one meeting on the submedian fold the double line which is filled with white and strongly bends towards the base below the costal margin, where it is broadly edged with white on both sides. Hindwing with but one quite indistinct darker straight transverse band. British Guiana.

terrena. **D. terrena** *Jord.* (= *orsilochus* *South.* nec *Maass.*) is similar to *samba*, paler, with broader hindwings. Both wings beneath with a very distinct black discal dot, the hindwing without the rusty brown apical spot which is replaced by a blackish macula. French and British Guiana.

6. Genus: **Metosamia** Drc.

Founded upon 2 Central American species which are very closely allied to the following genus *Telea* from which they merely differ in the wings being somewhat differently shaped; palpi extremely short, ♂ antennae with extraordinarily broad pectinations. In both wings 5 and 6 arise from the upper cell-angle. The apex of the ♂ forewing is very long, below it a long deep concavity; the same is the case with the hindwing, where the apex ends into a sharp point; the wing is dentate below the concavity, prolonged at 4 into a pointed angle. Both wings with hyaline spots.

Type: *M. godmani* Drc.

M. godmani Drc. (129 a). Above bright yellowish-red, costal margin ashy grey, the centre of the cell *godmani*. with a large white triangular spot bordered with pinkish carmine distally, with a straight similar line to the inner margin below the cell; a round hyaline spot bordered with yellowish-white and finely with black at the cell-end; subterminal line grey, outside narrowly white. Hindwing the same, without the antemedian line, the hyaline spot is more brightly bordered with white and exhibits another white crescent inwardly in the black border. The ♀ shows much larger hyaline spots and more broadly white-edged subterminal lines. Mexico. — **columbiana** f. n. (129 a) is much less reddish, more lemon-coloured, with more oval hyaline spots, the hindwing *columbiana*. is much less concave and dentate; apex not so far and pointedly produced; a darker median shadow of both wings being very faint in the nomenclatural form is distinct here, the white antemedian line is distally bordered with pink and also distinct on the hindwing, the subterminal line more intensely undulated, projecting on the veins. According to a fine couple from Western Colombia, c Coll. HOPP-Charlottenburg.

M. montezuma Sallé is very much like *T. polyphemus* from which it differs in its larger size, the more *montezuma*. produced apex of the forewing and much more intensely notched wings, beside the differences of neurulation: subterminal bands blacker, ocellus of hindwing smaller and surrounded by a distinct black ring, the interior light blue crescent distinctly outlined on both sides. Mexico.

7. Genus: **Telea** Hbn.

This genus contains but one well-known species; large and strong, with rather broad wings and a moderately produced, rounded apex of the forewing, below it the distal margin shows a slight concavity. Apex of hindwing rounded and only slightly produced. Structure of palpi, antennae etc. exactly the same as in the preceding genus. The stout, cylindrical larva exhibits the dorsum of each segment somewhat pyramidally raised and shows rows of small tubercles set with 2 bristles each. It pupates in a cocoon wrapped in leaves, which drops to the ground with the leaves in autumn.

T. polyphemus Cr. (= *paphia* L., *fenestra* Perry). Lighter or darker ochreous or purer light yellow *polyphemus*. (= ab. *flava* Grt.) with a blackish antemedian line bordered with white inside and interrupted on the median, *flava*. a broad grey and lilac white subterminal line and a round hyaline spot finely bordered with yellow and black at the cell-end. Hindwing similar, but the antemedian line is absent and the subterminal line is broader; ocellus very much larger, broadly surrounded by black and inside by blue. — **oculea** Neum. (= *aurelia* Drc.) *oculea*. (129 b) (the tricuspid apex of the forewing on the figure is added by the artist!) is a form extending to the south as far as Mexico, larger, with a more extended apex of the forewing and a longer produced apex of the hindwing, with a deeper concavity below it; ocelli larger, surrounded by a diffuse black ring on the forewing. — **olivacea** Ckll. is a form of a more olive brownish ground-colour. Also melanistic specimens entirely black *olivacea*, above are known, as well as albinotic specimens. The fine green larva with silvery white oblique stripes lives on nearly all kinds of foliage-trees and pupates in a dense cocoon. Occurring in the Northern U. S. A. in one generation, in the south in two.

8. Genus: **Tropaea** Hbn.

Conspicuous by the long tails of the hindwings into which the veins 1 and 4 terminate; the feeble cross-vein is almost straight in both wings. Apex of hindwing almost rectangular. Antennae of ♂ bipectinate, the pectinations much shorter in the ♀. Palpi extremely short; eyes relatively large. Chest peculiarly clad with fine woolly hair. Abdomen of ♂ rather slim. The cylindrical pupa shows very deep articular incisions and is set with rows of knobbed tubercles, as in *Telea*. Probably only one species occurs in America, though it is very variable locally.

Type: *T. luna* L.

T. luna L. This common species which is everywhere well-known and frequently bred is light green *luna*. with a purple brown costal margin with which a hyaline, red-edged discal spot is coherent; distal margin

dictynna. narrowly red-brown. In *dictynna* Wkr. a brownish discal band appears, the distal margin is not red-brown, less oblique, and the tails of the hindwings are shorter. A more southern form which seems to occur down as far as Mexico. — f. *mariae* Benj. is the spring-form from the Mississippi and Florida, showing a purple red margin beside the discal band; tails somewhat longer. — *rubromarginata* Davis, a spring-form from New York, shows a much broader red distal margin, in contrast with *dictynna*. — ab. *rossi* Ross. is a northern form in which the ♂ is of a pure white, the ♀ with a slight yellowish tinge (Toronto, Canada). — ab. *rubrosuffusa* Ckll. resembles *rubromarginata*, but the red colour of the distal margins, particularly on the hindwings, is still broader and proximally diffuse, 5 mm broad at the base of the tail, inwards suffused with light bluish, ocelli especially large. — *truncatipennis* Sonth. (130 b), from Mexico, is larger, the apex of the forewing more produced and somewhat truncate, the tails are longer and relatively somewhat broader, the red distal margin is narrow but much more distinct. — *azteca* Pack., from Nicaragua, has still shorter tails and a rounder apex of the forewing. Larva green with red tubercles, living on walnut, hickory, Liquidambar, and Diospyros. It pupates in a thin paper-like cocoon dropping to the ground with the leaves in autumn, as in *Telea*. In southernmore districts the species has two generations. A race bred in Europe (Switzerland) described as *bolli* Wagner is said to be smaller with shorter tails and smaller ocelli.

9. Genus: **Copiopteryx** Dunc.

This peculiarly beautiful genus resembles the preceding one by the formation of the tail of the hindwing, which however is different since also vein 5 participates in it, whilst the inner-marginal portion of the hindwing is extremely narrow, so that the lower cell-wall is almost contiguous to it and the inner-marginal veins, excepting the stronger vein 4, are almost entirely stunted; 3 arises on a long stalk from 4. Cell of forewing very broad, cross-vein very long, straight in its upper half, feebly concave in its lower half towards the margin; 5 arises almost from the centre of the cross-vein. The insects nearly all of which are very rare inhabit Tropical America, partly the highest mountains. Biologically little known.

Type: *C. semiramis* Cr.

semiramis. **C. semiramis** Cr. The nomenclatural type of this species originates from Surinam, the specimens before me from French Guiana (St. Laurent) probably correspond with it. Ground-colour very light reddish-brown, with a red-brown basal area, a pointedly triangular hyaline spot surrounded by brown at the lower discocellular; behind it with a light reddish dove-coloured narrow postmedian band, bordered with red-brown inwardly, notched between 6 and 8; apical area partly almost white, the apex itself red-brown at the distal margin; on the outside of the postmedian band between 3 and 4 a large triangular hyaline spot, below which there is a smaller one centred with a dark brown triangle; the lower two thirds of the marginal area red-brown. Hindwing similarly coloured and marked; tail very long and thin, more extensively brownish purple grey, bone-white at the end. — *steindachneri* Fassl (130 a), from the Bolivian Andes (Rio Songo), 1200 m, is larger, more variegated, the dark areas deeper blackish-brown, the light ones almost white especially at the apex of the forewing. Tails of hindwings somewhat shorter and broader. — *phoenix* M. & W. (*Deyrolle i. l.*), according to the figure of a ♀ e Coll. POGGE, from Central Brazil, has broader wings and is more uniformly coloured darker brown, the bands and apical area of the forewing are greyer, not so white. — *banghaasi* f. n. (130 A b), the northernmost form from Guatemala and Honduras, on the contrary is much more slender, the forewing much higher and narrower with a more oblique distal margin, of a more brownish-yellow ground-colour, the discal hyaline spot very narrow, not at all triangular, the broad subterminal band lilac grey, apical area reddish white, subterminal area only between 3 and 4 with a triangular hyaline spot; tail very long and narrow, deep brown and blackish-violet, only the last quarter light brownish yellow. Type: 1 ♂ e Coll. BANG-HAAS.

jehovah. **C. jehovah** Stkr. seems still to be an extremely rare species described according to a ♂ from Brazil and excellently figured. Ground-colour greyish-brown, slightly tinted reddish at the costal margin, the marking not dissimilar and intermediary between *semiramis* and the following *sonthonnaxi*; apical area of forewing scarcely lighter, the postmedian line very fine, distally very narrowly edged with white, strongly notched below the costal margin, with an almost trapezoid white hyaline spot between 3 and 4, a very small triangular spot above 5 and a pointed blackish-brown triangular spot below 3; basal area narrow, blackish-brown; the hyaline discal spot is pointedly produced outward at its lower end. Hindwing with a somewhat darker base, a slightly arcuate postmedian line behind the small discal spot; tails very long and thin. — By the kindness of Mr. O. *adaheli*. BANG-HAAS a different form is before me from French Guiana (St. Laurent): — *adaheli* *) f. n. (130 A c), in which the blackish-brown basal area is twice as broad, whilst the discal spot is strigiform and lacks the distal tooth beneath; the postmedian line is still more pointedly notched below the costal margin, the white hyaline

*) This name is about the same as Jehovah in the language of the Guiana Indians.

spot between 3 and 4 is obtuser, quadrangular, and near the anal angle there is another larger brownish-black triangle finely edged with white and bordered by two small ones. Hindwing basally not darker, without the postmedian line, and the antimarginal brown band is considerably broader.

C. virgo Zikan (= *biedermanni* Kotzsch) which was only recently described is about intermediary *virgo* between *jehovah* and *sonthonnaxi*, much neater and smaller than *semiramis*, the forewings shorter and less extended, olive brown as in *sonthonnaxi*, the lighter parts with a delicate pink hue; the dark olive brown postdiscal band is narrower than in *semiramis*, the distal band bordering on it contrastingly black; the very large hyaline spot, like a reverse y, is situate in a large reniform dark brown macula which is distinctly surrounded by black; the arch of the postdiscal band is flatter and more regular, the dark marginal area much narrower; the subterminal hyaline spots are larger and more coherent than in *sonthonnaxi*. Tails of hindwings as in *semiramis* but shorter. Expanse of wings: 90—100 mm, the hindwing from the base to the apex of the tail 97—116 mm. From Argentina, Paraguay, and Campo Bello (Rio de Janeiro).

C. sonthonnaxi André (130 a, d) is very similar, smaller and stouter, with much broader and shorter tails; *sonthonnaxi* more intensely marked dark blackish-brown, the postmedian line not notched below the costal margin, the hyaline spots behind it only distinct in the ♀. South Brazil, apparently a more common species.

C. derceto M. & W. (130 c) is the most bizarre of the species, yellowish-white, marked not unlike the *derceto* preceding ones, apex of forewing much more produced, the discal hyaline spot distally extended into a very long point. Hindwing much narrower, with much broader tails, discal spots tricuspid. From Brazil.

10. Genus: **Loxolomia** M. & W.

Only one rather isolated species peculiarly marked and structurally very closely allied to *Arsenura*. Palpi rather well developed, projecting a little beyond the frons; proboscis represented by a stunted thread. Antennae serrate with ciliary bristles. Wings rather elongated, costal margin slightly concave, with a convexity before the apex, distal margin slightly undulated. Hindwing with a produced apex, concave below it, with a broad lobe between 2 and 4. Upper half of discocellular of forewing straight, oblique, angled in the lower half, 3 shortly before the lower angle, 4 from this angle, 5 from the centre of the cross-vein, 6 from the upper angle, 7 and 8 stalked likewise from it; cell of hindwing exceedingly short, 2, 3 and 4 on a stalk from the lower angle, 5 from the angle of the discocellular which is shaped as on the forewing, 6 from the upper angle, 7 close before it. Nothing is known of its life.

L. serpentina M. & W. (128 c) is white; excepting the broad costal margin, a triangular spot edged with *serpentina* blackish-brown at the inner margin, and the disc of the hindwing it is dusted with olive brown in a variable intensity and transversely striated in a darker colour, with a double strongly undulated blackish-brown submarginal line; the large roundish apical area partly of a lilac brownish colour contains 3 red-brown longitudinal stripes edged with yellowish-white. Hindwing coloured like the forewing with a purer white median band edged with blackish-brown dentate lines on both sides. Brazil (Rio de Janeiro in January), a rare species.

2. Subordinate group: **Syssphinginae**.

Chiefly separated from the preceding genera by the more slender and pointed shape of the wings and the stronger abdomen, without any notches, angles and tails excepting the only *Syssphinx molina* which exhibits a slight angle on the forewing. Palpi mostly much feebler; the last third of the ♂ antenna is bare or feebly serrate and ciliated, the 2 basal thirds are pectinated, mostly also in the ♀♀; proboscis mostly rather distinctly present, though feebly developed. Posterior tibiae more or less spurred. Biologically, as far as is known, exactly like the species of the preceding subordinate group, the larvae with thorns and horns on the first and last rings which are often shed after the last moults. Pupation without a cocoon in the earth.

1. Genus: **Citheronia** Hbn.

This genus contains more than 2 dozens of described forms many of which are still doubtfully ranged. They are large, beautiful species mostly very sexually dimorphous, of a strong structure. The ♂♂ mostly with longer, narrower wings, the ♀♀ partly extraordinarily large, with broader wings. The short palpi do not project, the short last joint is almost globular; the proboscis is merely a short thread. The ♂ antennae, as far as $\frac{2}{3}$ or $\frac{3}{4}$ of their length, exhibit double short pinnae uniformly decreasing in length towards the ends and set with ciliary tufts. Tibiae with short terminal spurs. On the forewing vein 2 arises from the centre of the lower cell-margin, 3 a little before the lower cell-angle from which 4 proceeds; vein 5 arises shortly before the upper

cell-angle; the cross-vein is very strong in its short upper portion, very feeble in its long lower one and slightly angular shortly before the lower end. Vein 6 proceeds only a little behind the cell, 10 shortly before the upper cell-angle. On the hindwing 3 and 4 arise from the lower cell-angle, 5, 6 and 7 close together from the upper cell-angle. The abdomen in both sexes projects beyond the hindwing. The very strange larvae with their long horns, called "horn-devils" by the Americans, pupate without a cocoon in the earth, like the palaearctic *Brahmaeidae*.

Type: *C. regalis* F.

regalis. **C. regalis** F. (= *regia* A. & Sm.) (131 a) is one of the largest species, brownish-grey above, with red-brown veins and characteristic yellow spots. Hindwing without a distinct discal macula. The larva, the well-known "hickory-devil", is green with large oblique white lateral spots edged with black above; ring-indentations of the thoracic rings above black; head and thoracic feet yellowish-red like the spines the tips of which are black. It lives on many kinds of nut-trees and fruit-trees, also on Sumac. — *infernalis* Stkr. has slate-coloured forewings with brick-red veins, a large subapical spot and a smaller one in the centre of the distal margin; body brick-red. Maryland and North Carolina. — ab. *saengeri* Neum. has purple grey forewings with yellow veins and particularly large basal and discal spots and a bright sulphur-coloured apical portion of the costal and inner margins. Hindwing sulphur-coloured, with a basal orange tint, and traces of purple grey spots at the anal angle. New York. Widely distributed in the Atlantic States of North America.

azteca. **C. azteca** Schs. (131 a, b) is very similar, of a darker grey ground-colour, the spots more whitish yellow, the hindwing with a postmedian band of a most variable extent, mostly reaching to the marginal area in the ♀, always with a distinct red-brown central spot. This species represents *regalis* in Mexico, where it is very common.

splendens. **C. splendens** Drc. (132 a), likewise from Mexico, is easily distinguished by the expansion of creamy-white colour in and behind the cell-end at the costal margin. Hindwing extensively darkened towards the margin. Larva black, head, sublateral oblique stripes, and the base of the relatively short thoracic horns reddish, the other thorns black.

hamifera. *C. hamifera* Roths. is near to *azteca* and *brissoti* and may be considered as the representative of the latter species outside Brazil, but the genital organ is very different, the ♂ harpes are very large, almost semicircular. Veins of forewing only feebly reddish; hindwing above always with a reddish-brown submarginal band; the discal line feeble or extinct beneath, costal margin more or less reddish-brown or brownish-black.

hamifera. 2 forms have been described: — **hamifera** Roths., from British Guiana and Trinidad, shows the ground-colour of the forewing reddish-brown in the ♂, more blackish-brown in the ♀; the yellow band of the hindwing is only indicated, at least narrower than the reddish-brown marginal band; hindwings sometimes quite red-brown. — *fuscalis* Roths. has blackish-brown forewings also in the ♂, and the yellow submarginal band of the hindwing above is broader than the red-brown marginal band. From South-Eastern Peru, 2000 ft.

mogya. **C. mogya** Schs. (135 a) resembles *fuscalis* in general, but the wings are longer and narrower, and the colour of the forewing is a darker steel-grey; the postmedian row of spots straightly extends in an oblique line to the centre of the inner margin. São Paulo.

brissoti. **C. brissoti** Bsdv. (133 a), a Brazilian species, with somewhat broader wings, otherwise very much like the preceding ones. It differs in the more extensively yellow tegulae being only edged with red-brown, sharply outlined small discal spots in a yellow ground and larger apical spots which are more produced apically; hindwing often with a very distinct central spot. The species is variable; typically from Paraná, the Petropolis form shows the hindwings almost entirely dusted with red-brown. A strikingly different form with lighter grey forewings and quite light yellow hindwings, with separated red discal and inner-marginal spots, a broad postmedian and narrower marginal band is before me from Sa. Catharina: — **catharinae** f. nov. (135 a); type in the Berlin Museum (♂, ♀). — **argentina** f. n. I call the form from Buenos Ayres; it is much lighter dust-grey, all the spots yellowish-white, the postmedian ones not edged with red-brown distally, as in the Brazilians, but with greyish-black; hindwing with a large red-brown, triangular discal spot ending in a grey spot at the anal angle; costal-marginal area and distal margin extensively purely light yellow. Type in the Berlin Museum. The larva is greyish-green, strewn with black dots, the small thorns and fleshy cones are orange, the latter with black, knob-shaped ends, from the 4th ring with a lateral stripe. It lives on *Excoecaria biglandulosa*, an Euphorbiacea.

mexicana. **C. mexicana** G. & R. (132 a) is likewise similar, with Pompeyan red veins, yellow spots mostly strewn with red-brown except those between the veins 2 and 4, which remain purer yellow like the basal spots; thorax quite rusty brown, with hardly any yellow. Distributed in Mexico, also reported from Arizona. — **aroa** Schs. is probably the Venezuelan form; forewing lighter, mouse-coloured, all the spots orange, the submarginal undulate line broader. — **bellavista** f. n. (135 a) is a wonderful West-Colombian form, thorax lighter, rusty yellow, the spots on the forewing larger and very distinctly outlined; hindwing dark yellow with a red-brown

quadrangular discal spot and, separated from it, a basal inner-marginal spot, as well as a fine, rather indistinct postmedian line terminating in a large steel-grey spot at the anal angle. Type in the Coll. NIEPELT.

C. consobrina *Rothsch.* shows the same colour as *mexicana aroa*; hindwing more produced at the anal angle, with a discal band terminating in a blackish-brown spot at the anal angle. Under surface: the light markings are sulphur-coloured, hindwing dusted with rusty red and yellow below the cell. Genital organs very different, harpes much longer etc. South-Eastern Peru. *consobrina.*

C. beledonon *Dyar* (131 b) differs from *mexicana* in the lighter drab ground-colour, broader reddish-yellow veins and, above all, in the much larger creamy apical spots; all the spots and the submarginal line of a purer yellow without any red strewing. Thorax much more extensively yellow. Hindwing also in the ♂ much rounder. Mexico (Cuernavaca). — **colimae** *f. n.* (131 c) is smaller, with broader wings, inner margin shorter than distal margin, just as long in *beledonon*. The ground-colour is much darker, lead-coloured black, the veins finer orange, the spots more creamy white, not yellow. Submarginal band of hindwing more intensely and regularly notched, much blacker. Evidently the West-Mexican form from Colima and Guerrero. According to several specimens; type in the Coll. DRAUDT. *beledonon.* *colimae.*

C. collaris *Rothsch.* (133 a) is a very beautiful and easily recognizable species. Head and collar lemon-coloured; thorax and forewing purple brown, forewing dusted with violet especially at the costal and distal margins; postmedian macular band yellow, the other spots and the submarginal notched line orange, the uppermost spot produced into the apex. Hindwing with a large lemon-coloured spot in the centre of the inner margin, enclosing a round dark cellular spot; costal-marginal half and submarginal notched line orange brown. ROTHSCILD described the species according to a ♀ from Western Ecuador; a very fine ♂ which we figure is before me from Western Colombia, e Coll. NIEPELT. *collaris.*

C. guayaquila *Schs.* is evidently allied to the following species; head and thorax creamy white, shaded somewhat grey, abdomen reddish ochreous with yellow ring-indentations. Forewing brownish sand-coloured, the spots yellowish-white, arranged as in *claveryi*. Hindwing yellow in the costal-marginal portion, brownish claret-coloured in the basal half of the inner margin, dark greyish-brown in the terminal half with a dentate orange subterminal line. Ecuador (Guayaquil). *guayaquila.*

C. claveryi *Bouv.* (133 a) resembles *guayaquila*, but the body is more mixed with red-brown, the ground-colour of the forewing is brownish-red; hindwing yellow with indistinct subterminal lines and marginal band of a red-brown colour, the former widened in the inner-marginal part almost to the base. Ecuador (Rio Pastazza). *claveryi.*

C. phoronea *Cr.* (= *laocoon Dru.*) (133 a) approaches the *claveryi*-type. Forewing dark red-brown with a violet reflection, small orange postmedian spots, a large cell-end spot, 3 small spots of the ground-colour before the whitish cross-vein, 2 larger ones behind it; submarginal line feeble and irregular. Hindwing almost quite red-brown, yellow only at the costal and inner margins and in the faint subterminal line. Brazil. Larva blackish olive green, ventrally almost black, strewn with white, with a broad pinkish-white, slightly undulate lateral stripe, and lilac red thorns and fleshy cones. It lives on a parasitic plant. *phoronea.*

C. laocoon *Cr.* (= *anassa Hbn.*, *princeps Wkr.*) (132 b, c) is not to be mistaken for any other species by the shape of the broad yellow median area which is very narrow at the inner margin. Surinam. — **ixion** *Bsdv.* (133 b) is the stronger Brazilian form, especially from Novo Friburgo, separated by the somewhat duller colour especially in the females. — subsp. **lobesis** *Rothsch.* is a more northern form described from Costa Rica, in which the red-brown colour of the forewing is so extensive that the yellow is confined to a large cellular spot, some indistinct yellowish spots below it, and a very large subapical spot which is continued to the inner margin by a series of small yellowish spots. — Very similar is a form found in Mexico, which I denominate: — **jordani** *subsp. n.* (131 a as "*lobesis*"); forewing more pointed, distal margin more concave; forewing light grey; with fine yellowish-brown veins, the uppermost of the much larger apical spots extends into the apex as in *collaris*. Hindwing with a very broad macular band being almost black analwards. According to the kind information by Dr. JORDAN, the genitals are similar to those of *lobesis*, though they are somewhat different. According to several ♂♂ from Colima (West Mexico): type in the Coll. DRAUDT. — **marion** *Dyar*, from Panama (Trinidad R.), on the contrary is more extensively yellow, dusted with purple on the yellow ground in the basal area, as well as subterminally, deeper purple brown behind it at the margin. The yellow ground-colour of the hindwing exhibits a red discal spot and postmedian line, a red spot is near the inner margin below the cell. Larva light brownish sand-coloured, clouded darker in some places, with 4 or 5 fine, torn, black transverse lines composed of dots on each ring and a white sublateral stripe; thorns orange, the fleshy cones black, at the end orange with a black terminal knob. *laocoon.* *ixion.* *lobesis.* *jordani.* *marion.*

C. johnsoni *Schs.* belongs to the *laocoon*-group, but it is very different. Thorax reddish-yellow, collar bordered with red. Forewing dark greyish claret-coloured, veins red in the basal and marginal areas, in the median area only veins 1 and 2; two basal spots maize-coloured, the median area with larger partly confluent yellow spots separated from the subterminal row of spots by faded brownish shadows; small yellow and red internerval spots before the margin. Hindwing yellow with a large quadrangular red discal spot and a large round basal inner-marginal spot; the red dentate distal line terminates at the anal angle with a triangular spot. Rio Grande do Sul. *johnsoni.*

- armata*. **C. armata** *Rothsch.* (135 c) is separated from the other species by a long apical thorn on the anterior tibiae in both sexes. Forewing creamy, the chestnut-red veins finely striped black on both sides, the antemedian area, 4 small spots at the cell-end and a narrow subterminal row of sagittate spots are red-brown. Hindwing creamy with a red cellular spot, subterminal line and behind it with red, black-edged vein-streaks. Minas Geraes; Paraguay.
- vogleri*. **C. vogleri** *Weyenberg* (= *leona* *Drc.*) (131 d) differs much from all the other species in the black forewing with numerous small creamy white spots. Hindwing with a red cellular spot. Paraguay; Uruguay; Argentina.
- principalis*. **C. principalis** *Wkr.* (132 b) introduces an entirely different group; forewing reddish orange, strewn with brownish-grey, costal margin and marginal area with a light violet reflection, with 2 blackish-brown transverse lines, before the exterior one with 3, sometimes 4 hyaline spots which, however, may also disappear altogether: — **afenestrata** *f. n.*; type in the Berlin Museum. There are also specimens with a deep dark purple brown ground-colour dusted with light violet: — **purpurea** *f. n.*; type from Sa. Catharina in the Berlin Museum.
- afenestrata*.
purpurea. Larva dark green, strewn with white, warming into pinkish lilac on the dorsum of the 4th to 11th rings, from the 4th ring on both sides with large oblique lines edged with black above and extending across 2 rings each from in front above to behind below, with red branched thorns.
- fenestrata*. **C. fenestrata** *Rothsch.* (132 b) is similar, smaller, much darker, the subterminal arches therefore more prominently yellow; easily separable by a large white vitreous spot on the hindwing. Brazil.
- sepulchralis*. **C. sepulchralis** *G. & R.* (135 c) is a branch developed from the *mexicana*-type; almost uniformly chocolate-brown with fine dark veins and dark cell-end spots bordered with light just like a subterminal row of dark spots, the latter especially so towards the base in the ♀; a pinkish-red spot at the base of the forewing, a similar hue on the base of the hindwing. In the Atlantic States from Carolina to Massachusetts. Larva mostly from yellowish to purple brown with long yellow horns on the 2nd, 3rd and 11th rings and subdorsal, sublateral and substigmatal rows of thorns. It lives on Pitchpine: *Pinus nigra* and *mitis*.

2. Genus: **Eacles** *Hbn.*

Separated from the preceding genus by considerably broader wings with a less oblique distal margin, especially in the ♂, and correspondingly shorter abdomen. The lower portion of the cross-vein on the forewing is stronger, the origin of vein 5 removed somewhat deeper and, therefore, 6 arising nearer to the cell. Hindwing likewise broader, the cell considerably longer and the origins of 5—7 more separated from each other. Larvae, as far as they are described, similar to those of *Citheronia*, but much thicker and shorter with shorter fleshy cones and more scantily covered with longer hair.

Type: *imperialis* *Dru.*

- penelope*. **E. penelope** *Cr.* (= *cybele* *Oliv.*, *ducalis* *Wkr.*) (133 b). Orange, more or less densely speckled brown, dusted with red-brown in the disc, with two brown transverse lines bordered with lilac white on the averted sides, the interior line notched, the exterior line flatly undulate-dentate in its upper half; in the lower cell-angle a white ring centrally hyaline and bordered with brown, a smaller one above it, which may also be absent; distal margin excepting a subapical and anal triangle grey dusted with white; hindwing mostly purer yellow in the basal area, with the same ring-spot at the cell-end and red-brown dusting behind the exterior straight, undulate-dentate transverse line. Brazil. — **columbiana** *f. n.* is smaller, lighter yellow, the red-brown discal colouring is paler, but more extensive, the exterior transverse line quite straight, removed nearer to the discal spot on the hindwing. West Colombia. Type in the Coll. NIEPELT. Larva light green with a carmine dorsal line bordered with white, carmine thorns and fleshy cones, the spiracles surrounded with white and black.
- columbiana*.
majestalis. **E. majestalis** *sp. n.* (133 b) is much larger than *penelope* with somewhat narrower and longer wings, of a much brighter yellowish-red, in the basal area with a white round spot in a violettish-grey ring, just as large as the discal spots the centre of which is much more extensively hyaline; exterior transverse line violettish-black, inwards slightly convex and ending at the inner margin farther basad; here follows the transverse line of the hindwing in a straight direction, whereas in *penelope* it ends much nearer at the anterior angle at a great distance from that of the forewing. The grey marginal band of the forewing is much broader, particularly in the upper parts more intensely dusted with white; fringe at the ends of the veins only feebly traversed by light, broadly speckled in *penelope*. On the hindwing the transverse line is close at the discal spot. West Colombia; it cannot be a form of *penelope*, because it occurs together with its form *columbiana*. Type in the Coll. NIEPELT.
- barnesi*. **E. barnesi** *Schs.* is likewise closely allied with *penelope* from which it differs in 2 violettish-red discal spots with tiny white centres, and in the less straight, interrupted violettish-red transverse band of the hindwing, touching the discal spot which is coloured as on the forewing, behind it with a violettish-red marginal shadow between the veins. Beneath yellow, scarcely speckled black. Abdomen above violettish-red. At the base of the forewing 2 yellow spots, in *penelope* a small whitish spot. British and French Guiana.

E. niepelti *sp. n.* (133 c, d). A magnificent species; almost the whole forewing like the body fiery rusty *niepelti*. brown except 2 yellow basal spots, a slight yellow brightening around the latter, very large slate-black contiguous discal spots, a small apical triangle and the marginal area behind the exterior transverse line which contains some red clouds; the whole surface of the wings is speckled with blackish slate-colour; the upper exterior marginal half as far as up to the apex violettish-grey dusted with white. Hindwing yellow, a rusty brown longitudinal band below the cell is fused with a very broad exterior transverse band; discal spot as on forewing, above it another smaller one; margin narrowly red-brown. Under surface: disc in both wings suffused with salmon-colour and densely white-haired, so that the violettish-grey transverse bands look as if milk had been poured on them. The ♀ is quite cinnamon-red. ♀ from Guatemala c Coll. BANG-HAAS. According to 2 ♂♂ from West Colombia (Bella Vista). Type in the Coll. NIEPELT.

E. tyrannus *sp. n.* (133 c) is allied to *niepelti*, but the forewing with a sharper apex is of a deeper brown *tyrannus*. cinnamon-colour, not speckled at all, with an ochreous basal spot, a broad yellow brightening before the smaller and distinctly white-centred discal spots; transverse lines darker brown, not slaty black, interior line broad, indistinct, exterior line quite straight, only the lower half outside narrowly edged with yolk-colour; marginal area cinnamon-brown except a subapical triangular and an anal area, between them violettish-grey. Hindwing purely yellow only in the costal-marginal third, as well as in a narrow inner-marginal stripe and behind the narrow transverse line extending similarly as in *penelope*; marginal area broad cinnamon-brown, warming into purple grey distally; discal spot as on forewing. Abdomen with yellow bands. West Colombia (Bella Vista); type in the Coll. NIEPELT.

E. aglia *Fldr.* (133 c). For this species the genus *Bathyphebia* was established, but it is a genuine *aglia*. *Eacles*, which may be considered as an extreme branch of *tyrannus*. Forewing rusty brown, yellow in some places, as in *tyrannus*; transverse lines thick black, the large discal spot black, with a white centre and yellow ring, a large yellow triangle before the apex. Hindwing yellow in the costal-marginal half, otherwise red-brown with a large black white-ringed ocellus as on the forewing, behind it a black transverse stripe which is incurved towards the interior angle. Colombia (Bogota).

E. gschwandneri *Schaw.* may be a form of *aglia*, though it looks rather different. It is larger, deeper *gschwandneri*. chestnut-brown, yellow are only the head and collar, the 1st abdominal segment and a small basal spot; the anterior black transverse line is absent altogether, the posterior one is scarcely visible and separates the brown ground-colour from a snow-white band extending from the apex to the 3rd quarter of the inner margin; the small punctiform discal spot is white without the black border; hindwing yellow in the costal-marginal portion, the white ocellus very large and with a deep black ring; the transverse stripe is broadly edged with white also here, and extends straight into the inner margin. According to 1 ♂ from the Volcano of Tolima (Colombia).

E. mayi *Schs.* (= *lombardi* *Bouv.*) (133 d) is closely allied to *barnesi* and *niepelti*, but much smaller, *mayi*. the apex of the forewing more produced; forewing yellow, speckled blackish, suffused with red-brown basally, in the disc and behind the cell, with 2 smaller slaty grey round spots scarcely lighter centred at the cell-end; the anterior transverse stripe is quite extinct, the posterior one straight from the apex to $\frac{2}{3}$ inner margin, broad, brownish-red, the margin behind it suffused with violettish-grey. Hindwing purer yellow in the basal half, a basal spot and the margin broad red-brown, discal spot more intensely centred white. Brazil, but apparently more widely distributed, for a ♂ is before me from Guatemala, c Coll. BANG-HAAS, which we figure and which only differs from the type in the discal spot of the hindwing being quite red-brown.

E. eminens *Dogn.* (133 d) has much broader wings than the preceding species, much more extensively *eminens*. yellow, so in a large apical triangle and in the lower half of the forewing also before the exterior transverse stripe; both the discal spots of the forewing and that of the hindwing brightly centred with white; the broad red-brown band of the hindwing, which is shaped similarly as in *niepelti*, is broadly confluent with the margin in the upper half; the ♀ is quite yellow, little and finely speckled. Ecuador.

E. adoxa *Jord.* is allied to *eminens*; smaller, distal margin of forewing slightly concave, posterior angle *adoxa*. less rounded; marginal area except a small anal spot quite dark reddish-brown, more extensively dusted with grey than in *eminens*. Hindwing oval, the whole distal half deep tan-coloured brown with an interrupted yellow anal spot; discal line outside narrowly bordered with yellow. Expanse of wings: 42 mm. According to 1 ♂ from British Guiana.

E. masoni *Schs.* (131 c) recalls *tyrannus*, but the apex of the wing is much sharper, more sickle-shaped; *masoni*. the bright red-brown colour is covered by a duller violettish-grey; yellow remains an area before the interior transverse line, a large apical triangle and a narrow anal area behind the exterior transverse line, also a narrow area behind that of the hindwing; discal spots of the forewing very insignificant. Mexico to Panama. — **fulvaster** *Rothsch.*, from South-Eastern Peru, has a deeper yellow ground-colour, the reddish dusting is more *fulvaster*. extensive and prominent, with a larger yellow spot at the apex of the cell, whilst the anterior cellular spot is entirely absent. Ventrums and faces reddish; genitals very different.

E. acuta *Schs.* (= *callopterus* *Rothsch.*) is very similar to *masoni*, but somewhat smaller, the forewing *acuta*. still narrower and more pointed, the postdiscal line is nearer at the margin and, like the marginal band, suffused with reddish-violet, like the basal and discal portions, too; a broad yellow band before the posterior transverse

line from the costal margin almost to the inner margin; the round cellular spot is transparent, bordered with violettish-grey. Hindwing narrower than in *masoni*, inner margin longer than the costal margin, the margin less rounded, a subbasal spot, the posterior transverse line and a marginal band violettish-grey with a reddish hue. British Guiana; South-Eastern Peru.

ormondei.

E. ormondei Schs. (131 c) is again more similar to the *niepelti*-group, but much more abundantly yellow, forming the transition to the following *imperialis*. The ♀ is almost quite yolk-coloured, feebly tinted red-brown, intensely speckled blackish-brown, all the transverse lines except the exterior one of the forewing very undulate-dentate. All the discal spots with black rings and greyish-white centres. Mexico.

guianensis.

E. guianensis Schs. resembles *imperialis*, but the lines and spots are different. The yellow forewings are almost entirely suffused with dark violet except a large apical spot and at the inner margin on each side of the exterior transverse line which is very broad, as well as the interior one; marginal area not striated at all; a hyaline spot with a violet ring at the cell-end. On the hindwing the broad distal line is interrupted by the discal spot, the margin is speckled violet, with violet marginal spots between the veins; the violet irregular basal band is expanded towards the inner margin and extends upwards only into the cell. British and French Guiana.

imperialis.

E. imperialis (= *imperatoria* Abb. & Sm.) has an enormously wide range extending from the United States down to Argentina. — **imperialis** Dru., the nomenclatural form from North America, is yellow in the ♂, more or less intensely speckled dark in the larger basal half, and brownish-violet before the margin, as well as in the inner-marginal area of the hindwing, the anterior transverse lines are invisible, the posterior ones undulate-dentate, the discal spots centred light violettish-grey. The ♀ is quite yellow, the basal transverse

oslari.

lines of both wings distinct and broad. This is the form of the Atlantic States. — **oslari** Roths., from Arizona, has as broad wings as those of the Atlantic specimens, both sides of the hindwing show a broad discal line

magnifica.

widening in front. — **magnifica** Wkr. (= *cacicus* Bsdv.) is larger, stronger, and much more brightly coloured, likewise with rather broad wings, but with a more pointed and almost sickle-shaped apex. On the ♂ antennae

decoris.

fewer segments are pectinated than in *imperialis*. Mexico to Paraguay. — **decoris** Roths. (132 c as "imperialis") is intermediary between the two preceding ones, the antennae as in *imperialis*, i. e. more segments are pectinated than in *magnifica*. Forewing somewhat narrower, but less pointed and sickle-shaped than in the latter form; discal line as broad as in *imperialis*, broader than in *magnifica*; basal area yellow, the anterior transverse line as broad as in *imperialis*. This is the Central-American form from Mexico and Guatemala, but almost typical

approximans.

magnifica-forms occur already in Mexico. — **approximans** Bouv., described from Venezuela, resembles *magnifica* in general, but it is smaller and shows much smaller discal spots. — **opaca** Burm., from Southern Brazil, is very

opaca.

light yellow, the violettish-brown colour turns more blackish-brown and does not extend to the discal spots in the ♂, but it may also cover almost the whole forewing. The specimens are small, with narrow forewings,

tucumana.

but the apex only little pointed sickle-shaped. — **tucumana** Roths. resembles *magnifica*, forewing very pointed, discal line broad above and beneath, continued to the inner margin. Hindwing likewise with a broad discal

punctatissima.

line on both sides. Argentina. — Aberrative forms have also been described, e. g. — **punctatissima** Neum. in which all the blackish-brown striae are so much increased and confluent at the base and inner margin that the ground-colour appears to be monotonously blackish-brown, only the costal-marginal area of the hindwing

didyma.

being yellow. — f. **didyma** Beauv., quite monotonously dull cinnamon-red, the basal portion and marginal area with a greyish-violet hue. All the yellow tints have also disappeared on the body. — **nobilis** Neum. (135 b) is

nobilis.

like *didyma*, densely strewn with black, but with a deep rusty-red triangular area in the apical half, the base of it being the costal margin, and the apex on the median. From North-Western Texas. — Larva green or brown with oval yellowish-white, dark-ringed spots above the somewhat darker lateral line; the 2nd and 3rd as well as 11th rings exhibit longer hairy yellowish fleshy cones, the other rings tubercles with tufted hair. It lives on nearly all kinds of trees and shrubs and changes into a smooth black pupa.

3. Genus: **Syssphinx** Hbn.

As there are no essential differences between *Syssphinx* and *Adelocephala*, the former name must have the priority. We combine with it also *Othorene* Hbn. and *Sphingicampa* Walsh., because they cannot be strictly separated. In general very similar to *Citheronia* from which they are at once separable by the absence of vein 9 of the forewing. Compared with the long pointed wings the body is still stronger, the prothorax is very convex, so that the small head with the very short palpi is pressed down and not visible from above. The abdomen projects far beyond the hindwings, at least in the ♂♂. Costal margin of hindwing very convex basally, cell short. Antennae of the ♂♂ pectinated in the basal halves, set with fine cilia in the distal halves. A great number of species which are often difficult to distinguish.

Type: *cadmus* H.-S.

hodeva.

S. hodeva Drc. (= *rubra* Schs.) (135 d) is one of the largest species, above brown with a dark violet reflection, with a white discal dot and 2 transverse lines, a subterminal purple brightening behind the exterior line. Hindwing brownish carmine. Guiana to Brazil.

S. cadmus *H.-S.* is very similar to *hodeva*, the median area more rust-brown, coarsely speckled with blackish brown, hindwing turning red-brown towards the margin with an indistinct median band; behind the exterior oblique line somewhat lighter lilac only towards the apex. Brazil (S. Paulo). A form found in Mexico is: — **castanea** *Pack.* lacking the discal spot, with rounder hindwings, not red in the distal third.

S. verana *Schs.* (135 d) has broader wings than the two preceding species, variably coloured, but generally lighter, fawn-coloured or tawny, the centre of the exterior transverse line slightly convex inwards, below the apex slightly outwards, lighter violet behind it, the median area between the lines somewhat darker, the white discal dot rather inconspicuous, surrounded by a somewhat darker brown, or absent. Hindwing not or but little darker than forewing. Mexico.

S. intermedia *Rothsch.* is very closely allied to the following *purpurascens* and may be a form of it; the blackish transverse lines are more distinct; the ♀ resembles *verana*-♀, the ground-colour is deeper, the lilac shading along the lines more distinct. Costa Rica. Genital organs different from those of *purpurascens*, clasper pointed, not truncate or sinuate at the end.

S. purpurascens *Schs.* is a magnificent species, dark chestnut-brown with a white discal dot in a shadowy spot; 2 blackish lines are edged with pinkish lilac on the averted sides, the most intensely so near the inner margin, lighter lilac also subapically. From Guiana to Rio de Janeiro. — **intensiva** *f. n.* (135 d). from West Colombia, is much brighter and deeper coloured, the pinkish lilac very bright; apex of forewing more pointed. Type in the Coll. NIEPELT.

S. pollens *Schs.* is similarly marked, median area olive brown, basal and marginal areas lilac, transverse lines fine, black, the exterior one from the apex to two thirds of the inner margin; discal dot white. Hindwing dark red, costal margin and distal margin tinged with pink, a large black spot at the cell-end. Costa Rica.

S. talamanca *Schs.* as well as the following *jacca* are probably merely variable forms of *pollens*, since all were taken at the same place and time in March. Body and wings more reddish-brown, scantily and finely striated black, hindwing brownish ochreous, only red in the disc and at the inner margin. — **vilderi** *Schs.* Above brownish ochreous, thorax lilac; forewing lilac, brownish-ochreous in the median area, with very prominent dark lines, the exterior one angled on vein 2 and extending outwards to the inner margin. Costa Rica.

S. jacca *Schs.* has broader wings than *pollens*, otherwise very much like it. Body light brown, with a lilac tint on the thorax and beneath, the brown forewing also at the basal and marginal areas; a fine dark line extends from the apex behind the centre of the inner margin; a silvery white spot in the lower cell-angle, above it a white streak. The red hindwing is brownish at the margin. Guatemala (Cayuga).

S. centrimacula *Strd.* is described according to 1 ♀; coloured like the median area of *cadmus*, but not quite so light as in *fallax*, the marginal and median areas very finely striated black, with a brownish blotch on the cross-vein and 2 dark transverse lines, the proximal one vertical to the inner margin, the distal one extending from before the apex to the centre of the inner margin. Hindwing with a faint reddish hue in the centre. Ecuador (Macas).

S. flavosignata *Wkr.* (= *wardi* *Bsd.*, *eugenia* *Drc.*) (136 a). Body yellow, thorax in front lilac, abdomen with a rusty brownish hue. Forewing of ♂: lilac on the yellow ground at the costal margin, in the median area and in the upper marginal half, darker yellow in the apical half, densely speckled purple; 2 or 3 oval silvery white spots at the cell-end. Hindwing only yellow in a marginal band, otherwise red-brown and dusted with violet. The ♀ is quite violettish-brown with a darker median area, the interior indistinct border concave towards the base, the exterior border strongly curved, in the centre concave towards the margin. Mesothorax yellow. Colombia, Brazil. Larva green with violet horns and silvery thorns; it lives on Papilionaceae, especially thorny Mimosae.

S. tristygma *Bsdv.* is very similarly marked, but the basal and marginal areas are reddish lilac, the median area orange, the 3 silvery spots as in *wardi*; the distal transverse line is almost straight, feebly convex inwards. Brazil (S. Paulo). — **plateada** *Schs.* (136 a) shows a lilac tinge and blackish speckles towards the inner margin in the median area, the distal oblique line is undulate-dentate. Guiana. — **amazonica** *Rothsch.* resembles *plateada*, the black markings are more distinct, the forewing beneath with a large black angular cellular spot, the other forms without it or only with a fine black discal streak. Fonte Boa (Amazons).

S. polybia *Stoll* (136 a) has relatively broad wings, orange brown, the median area with a light lilac tinge towards the costal margin; 2 black transverse lines almost meet at the inner margin, the proximal one is flawed on the submedian fold, the distal one from before the apex to the centre of the inner margin, the space between both from vein 2 to the inner margin is filled with white. Guiana. — **longispina** *Rothsch.* described as a form of it is genitally different, the dorsal appendage of the anal tergite is much longer, the ventral end of the clasper with a short obtuse lobe, hook-shaped in *polybia*. Distal line beneath removed more towards the margin. South-Eastern Peru.

S. janeira *Schs.* has orange forewings with a purple tinge along the costal margin, and darker grey veins and fringes; a dark grey line from the apex to the inner margin near to the base, a large white spot at the

base. Hindwing deep yellow, red along the inner margin, with a narrow dark transverse band. Body orange, redder above, with a large white spot on the base of the abdomen. Brazil (Rio de Janeiro).

- arpi*. **S. arpi** Schs. (136 b). Forewing deep orange, veins, inner margin and distal margin grey, a large triangular median area also grey, its upper edge occupies almost the whole costal margin, bordered by darker lines which are united at or above the inner margin and often surround here a tiny white spot; a large orange spot at the cross-vein, a white one at the base. Hindwing brownish in the larger inner-marginal half. Brazil (Rio de Janeiro).
- carabaya*. **S. carabaya** Rothsch. Colour and contours of wings as in *arpi*, wings somewhat longer than in *polybia*, margin of hindwing less round; the two transverse lines are united either at vein 2 or behind it, the small space between them may also be filled with white. Genital organs very different: anal tergite excavated at the apex, 2 small sharp hooks above the sinus as in *polybia*, but no dorsal appendage, the long harpe terminates in a black pointed hook. South-Eastern Peru.
- subochreata*. **S. subochreata** Schs. (= *bipuncta* Dogn.) is not synonymous with *polybia*, as ROTHSCILD presumed. Thorax reddish-brown, abdomen more ochreous. Forewing reddish-brown with a white spot at the base, a white dot before the centre of the inner margin, another one above it below vein 2; a triangular violetish-pink area at the costal margin; the upper distal apex in the last quarter of the costal margin, parallel to the distal margin, extending down to vein 4. Hindwing red-brown, tinged violetish-red at the inner margin. Colombia.
- klagesi*. **S. klagesi** Rothsch. (136 b) entirely resembles the preceding species, but it lacks the two white dots at and above the inner margin. Surinam and British Guiana.
- adocima*. **S. adocima** Dyar is very similar to *klagesi*, the forewing is dark greyish-brown, with a white triangular spot at the base, faint traces of a distal line extending from the distal fifth of the costal margin towards the inner margin, pronounced at the costal margin by a proximal triangular violet brightening. Abdomen brownish ochreous. Panama.
- columbia*. **S. columbia** Schs. (= *nisa* Drc.). Body yellowish-brown, head and border of collar pink. Forewing violetish-pink with a broad, dark-edged, yellowish-brown band from the apex to the centre of the inner margin, a small white spot bordered with pink at the cell-end. Hindwing pinkish-brown with pink fringe. Peru.
- ocellata*. **S. ocellata** Rothsch. (136 b). Brownish orange, tegulae, base, and margin of forewing dusted with lilac pink, with the usual 2 oblique lines, between them a white mostly double cellular spot. Hindwing more reddish, costal and distal margins lighter. In the nomenclatural form from South-Eastern Peru, the white cellular spot is transverse, at least beneath, where the species is separated from the many similar allies by the large black, white-centred cellular spot of the forewing; fewer than 20 antennal segments are pectinated, whilst in —
- bidens*. **S. bidens** Rothsch., from Venezuela, more than 20 segments are pectinated, the central spot beneath rounded, with a round white centre; the dorsal appendage of the anal tergite is longer than in *ocellata*, the clasper shorter than in the latter.
- adusta*. **S. adusta** Rothsch. (136 c). Body above reddish-orange, head and ventrum lighter, more yellowish; antemedian line straight, the posterior one almost straight, both brownish black, the median area between them orange, base and margin with a reddish-violet hue, in the margin 2 large shadowy spots. Hindwing rounder than in *jason* and *nisa*, reddish orange as far as the feeble postmedian line, reddish-brown behind it, reddish at the cell-apex. South Eastern Peru.
- curvilinea*. **S. curvilinea** Schs. ♂ above dark brownish ochreous, with a lilac hue at the margin of the forewing, a fine dark reddish-brown line from the costal margin near the apex to the centre of the inner margin, from where the line rises again almost to the costal margin; a feeble transverse streak at the cell-end. Hindwing with a feeble reddish transverse line. In the ♀ the interior portion of the line is more oblique and parallel to the exterior one; hindwing tinged with red. Expanse of wings: ♂ 68, ♀ 91 mm. Coatepec, Mexico. Allied with
- boulleti*. *jason*. — f. **boulleti** Bouv. chiefly differs from *jason* in the course of the two transverse lines which meet at the inner margin. The specimen lacks the white discal spot which is replaced by a straight streak on the cross-vein. Described after 1 ♂ from Rio de Janeiro.
- fallax*. **S. fallax** Bsdv. (136 e). Body and wings orange, marginal area and base dusted with whitish violet with 2 reddish-brown transverse lines, the interior one obliquely inwards to the inner margin, the exterior one from the apex, distally concave below the centre, with or without a white cellular spot. Hindwing with rust-brown hair at the inner margin. Brazil.
- marginata*. **S. marginata** Bouv. Allied to *jason*, the distal margin of the forewing convex. Reddish ochreous, tinged with pink behind the distal oblique line; lines blackish-brown, the anterior one straight, the posterior one from a little before the apex to the inner margin; a white spot bordered with black-red at the cell-end. Hindwing reddish-ochreous, suffused with violet; abdomen pinkish-grey. French Guiana.
- jason*. **S. jason** Bsdv. (= *montezuma* Pack.) (136 e, d). Bright orange ochreous, scantily strewn with dark, basal area slightly tinged lilac; very feebly so also the extreme margin; lines blackish-brown, the interior one

vertical to the inner margin, the exterior one from before the apex, a very small white dot in the lower cell-angle, absent in the ♀. Inner margin of hindwing with darker red hair. Mexico to Colombia and Brazil.

S. subangulata H.-S. (= *obscura* Bouv.). Thorax pinkish greyish-brown, abdomen smoke-brown; *subangulata*. forewing in the median area coloured like the thorax, basal and marginal areas darker brown, with a slight pink tinge; anterior transverse line almost straight, at the costal margin more remote from the base than at the inner margin, the exterior oblique line very obliquely from the apex to the centre of the inner margin, very slightly convex inwards; discal spot darker. Hindwing with a feeble transverse line, tinged pink. Beneath the disc of the forewing is red, the black spot not centred white. Mexico to Brazil. Larva dark green with a blue head and lateral stripe, with silvery thorns on the middle segments, the thorns on the 2nd and 3rd rings very long, dentate, black. It lives on a thorny creeper.

S. acuta Schs. (136 b) has a pinkish-brown body. Forewing very pointed, reddish-brown, dusted with *acuta*. lilac basally and at the margin, the interior line from the centre of the costal margin to the interior third of the inner margin, the exterior line from the apex to $\frac{2}{3}$ inner margin, an indistinct grey, white-centred spot at the cell-end. Hindwing reddish-brown, with red hair at the inner margin. Beneath orange with a large grey marginal triangle and a large black, white-centred spot at the cell-end. Venezuela (Aroa); West Colombia.

S. catoxantha Roths. is larger than *subangulata*, the forewing more pointed, the oblique lines more *catoxantha*. prominent, beneath yellow instead of red; lighter and smaller than *acuta*, hindwing above only with a red spot; instead of being quite red, the black cellular spot of the forewing beneath is centred white. Venezuela, South-Eastern Peru.

S. lacrimata Dogn. is somewhat smaller but otherwise very similar to *catoxantha*, at the cell-end of the *lacrimata*. hindwing above there is a very large, distinct, lachrymiform black spot the pointed end of which is directed upwards; median area of forewing above pinkish-grey, hindwing beneath quite pink without the ochreous dusting like *catoxantha*. Amazons.

S. irrorata (= *irrorata* Schs. ex err.) (135 e) is light reddish-brown in the ♂, feebly strewn with lilac, the *irrorata*. narrow basal area, the distal margin behind the line and a large round discal spot are lilac; interior line indistinct, very near to the base, the fine distal line lilac, from the apex slightly curved to $\frac{2}{3}$ inner margin. Hindwing pink, costal and distal margins with a light brown hue. Beneath basally and in the disc pink, costal margin yellowish-brown, distal margin lilac, the line red, a large black discal spot before it. In the ♀ the brown forewing is more densely striated black and lilac, the discal spot hardly visible, the fine dark distal line straighter than in the ♂. Expanse of wings: ♂ 58, ♀ 79 mm. Mexico (Jalapa, Orizaba).

S. yucatana Drc. Body and forewing yellowish-brown, forewing densely strewn with dark brown, the *yucatana*. brown oblique lines feeble, an indistinct brown spot at the cell-end. Hindwing rosy red, yellow at the distal margin. Beneath without lines, with a large black spot on the forewing. Yucatan.

S. carisma Schs. is reddish-ochreous on the front body, the tegulae inside bordered with dark grey, *carisma*. abdomen tinged lilac laterally and beneath. Forewing reddish ochreous, strewn darker, inner margin fine lilac grey; the fine dark antemedian line straight, the posterior transverse line extends from near the apex to the centre of the inner margin, distal margin tinged lilac, the white discal spot surrounded by dark, a dark dot above it; hindwing red-haired at the inner margin, apex slightly dusted with dark. The ♀ is browner, more intensely strewn with black, with 2 small black discal dots. Hindwing reddish with a dark transverse line through the centre. Expanse of wings: ♂ 63, ♀ 96 mm. British Guiana.

S. guianensis Bouv. is very closely allied to *jason* by its shape and colour, but it differs from it in 2 *guianensis*. small white discal spots and in the absence of the black discal spot on the forewing beneath; distal margin quite straight, the veins not prominent in the distal portion; the inner margin of the hindwing lacks the dark red-brown spot; distal portion of forewing dusted with pinkish-grey. A smaller species with an expanse of 57 mm. French Guiana.

S. brevis Wkr. (= *convergens* H.-S.) (135 e). Reddish-brown, with a feeble lilac tinge, black veins, *brevis*. 2 transverse lines convergent towards the inner margin, the distal one lighter inwards, a short feeble streak at the cross-vein; separated from *anthonilis* by shorter and broader wings. Brazil. Larva very similar to that of *subangulata*, yellowish-green with golden thorns, and living on Mimosa.

S. lanaris Roths. Shape and colour very similar to *brevis*, antennae with 16 pectinated segments; *lanaris*. forewing less long, margin broader, the distal oblique line thinner, proximad more distinctly bordered with grey. Hindwing rounder, particularly analwards, the reddish spot smaller. Forewing beneath loam-coloured not ochreous towards the inner margin. Genitals very different. Bahia.

S. anthonilis H.-S. is more greyish-brown, the distal oblique line very broadly bordered with greyish- *anthonilis*. white inwards. Hindwing with a slightly curved brown postdiscal line. Brazil. — **analis** Roths. (135 e) has *analis*. somewhat broader forewings, the two lines are more separated, the distal one more remote from the cell. Clasper-wool ochreous. South-Eastern Peru. Southern Colombia. The black larva with reverted thorns lives on various foliage-trees in 2 generations.

- homoca.* **S. homoea** Rothsch. (136 d) is similar to *analis*, larger, body and wings slightly tinged with claret-colour; forewing longer, the interior angle more rounded, the anterior transverse line more oblique, at the costal margin near the cell-apex. Hindwing with a less round costal margin and distal margin. Clasper-wool like the abdomen, not ochreous. South-Eastern Peru.
- pelias.* **S. pelias** Rothsch. (135 e). Thorax and base of abdomen ochreous, abdomen posteriorly tinged rosy-reddish. Wings loamy ochreous, forewing with straight blackish oblique lines, basal and marginal areas pinkish-brown, a round white cellular spot in the lower cell-angle; wings longer than in *boisduvalii*, speckled with blackish-brown, bordered with dark at the inner margin. Hindwing oval, distally rounded, yellowish ochreous, loamy brownish at the margin with an indistinct blackish median line not reaching to the inner margin. Length of forewing: 52 mm. Bolivia; Chanchamayo.
- bellardi.* **S. bellardi** Schs. ♂ salmon-coloured reddish ochreous on the anterior body, base and end of abdomen, the rest of the abdomen pink, legs more lilac pink. Forewing pinkish-brown at the base and marginal area, deep chromatic yellow in the median area with some rust-brown striae; transverse lines olive brown, anterior line excurved, and angled in the cell almost to the base of the inner margin, the exterior line from the apex to the centre of the inner margin, a brownish-pink spot at the cell-end. Hindwing reddish ochreous, somewhat red-brown at the inner margin, with a feeble brownish-red distal line. Costal margin of hindwing strongly convex basad. Expanse of wings: 43 mm. Valera, Venezuela.
- andrea.* **S. andrea** Dogn. is yellow above, rather regularly speckled with black, with a thick discal dot and a black line extending from shortly before the apex to the 2nd third of the inner margin and very slightly curved inwards. Hindwing lighter yellow, not striated, with bright red hair in the two interior thirds, and a shadowy spot behind the cell on 5 and 6. Expanse of wings: 62 mm. Described after 1 ♂ from Venezuela (Caracas).
- mexicana.* **S. mexicana** Bsdv. (= *xanthochroia* Dyar) (136 c). Deep yellow, basal and marginal areas rarely dusted with violet, oblique lines violettish-brown, a double white spot in a violet ring at the cell-end in the ♂, whilst the ♀ shows a violettish-brown round blurred spot. Hindwing with dark red hair in the inner-marginal half. Mexico.
- boisduvalii.* **S. boisduvalii** Doum. has somewhat broader, lighter yellow wings, the oblique lines are nearer together, the hindwing is less and lighter red at the inner margin. Brazil; scarcely to be separated specifically from *mexicana*.
- smithi.* **S. smithi** Drc. differs from the preceding species in the absence of oblique lines and of the cellular spot, light yellow, densely speckled brown, especially at the base. The yellow hindwing shows dark red hair at the base of the inner margin. From Colombia.
- lineata.* **S. lineata** Drc. is likewise light yellow, but much smaller, the forewing basally greyish-brown, a white dot at the cell-end, behind it a greyish-brown line from the apex to the inner margin near the base. Hindwing monotonously light chrome-coloured. Paraguay.
- quadri-lineata.* **S. quadrilineata** G. & R. Forewing reddish ochreous, base and marginal area tinged lilac, with the usual red-brown oblique lines and 2 large white spots at the cell-end. Hindwing extensively red. Missouri, Mexico, Costa Rica to Colombia. Specimens with only one white discal spot are called: — **unimacula** Dogn. (136 d), whilst those in which even this spot is absent and replaced by a shadow, are: — **occlusa** Dogn. Forewing beneath with a large black, white-centred spot at the cell-end.
- bisecta.* **S. bisecta** Lint. (136 e) has a straighter costal margin, a more oblique distal margin and shorter and rounder hindwings than *bicolor*. Body ochreous, tegulae more pale lilac than the base and marginal area of the forewing, the median area bright ochreous and finely striated dark; without a discal spot or with a feeble oval ring; postmedian line feebly curved from near the apex to the centre of the inner margin. Hindwing ochreous, pinkish carmine in the disc as far as the inner margin. The ♀ is monotonously light reddish-brown, striated darker. — **nebulosa** Neum. is hardly worth being denominated and has a more distinct posterior transverse line and blackish-brown discal spot, more yellow hindwings. Larva like that of *bicolor*, but without the silvery horns. Texas.
- nebulosa.* **S. hoegei** Drc. (137 a) is a marvellously variable species; among almost 50 specimens before me there is hardly one like the other. Orange, more or less finely speckled red-brown, or all over suffused with red-brown, with or without lilac dusting at the basal and marginal areas, transverse lines as usual, the posterior one from the apex or before it, at the cell-end one or two white spots which, if they grow larger, form two triangles with their apices upon each other like a sand-glass. ♀ without white spots. Hindwing more or less extensively carmine. Specimens with a purely yellow median area and a purple basal area and marginal area are called: —
- montana.* **montana** Pack. (= *phaedima* Dyar) (137 a), the hindwing is carmine in the disc, yellow at the margin. —
- kuschei.* **kuschei** Dyar is the northernmore form, from Sinaloa, a smaller form with a rounder apex, an entirely brownish-grey forewing and red hindwing without a yellow margin. The same form, but with yellow forewings, is called:
- sinaloana.* — **sinaloana** Schs. Distributed in Mexico, also in Arizona.
- dollii.* **S. dollii** Pack. I do not know. Larger than *hoegei*, body and wings reddish-brown, as in *Anisota stigma*, with a lilac tint, not striated; anterior transverse line very indistinct, posterior line regularly curved, to the apex; discal spot small, white. Beneath without the discal spot. Mexico.

S. colla Dyar is very similar to *colloida*, somewhat larger, less densely strewn with blackish, the forewing *colla*. with white cell-end maculae. An indistinct blackish cellular spot on the red hindwing. Described from Mexico.

S. colloida Dyar (137 a). Forewing loamy yellowish-grey, the margin feebly tinged with lilac, densely *colloida*. speckled with blackish, only the exterior transverse line indistinctly noticeable by somewhat denser speckles, somewhat more densely speckled at the cell-end, occasionally with a feeble whitish dot in the centre. Hindwing carmine in the disc with a large black central spot which is blurredly continued towards the costal margin, marginal area as on forewing. Mexico (Colima).

S. bicolor Harr. (= *distigma* Walsh.) (137 b) is ochreous, densely striated darker, or light Isabel- *bicolor*. yellow often with a faint pink tinge; antemedian line scarcely noticeable, posterior transverse line slightly curved, interrupted by the veins from before the apex to the centre of the inner margin; 2 discal spots may be quite absent, or only one present. Hindwing carmine, ochreous at the margin, lighter towards the anal angle. Body ochreous. — **suprema** Neum. is brightly coloured with 2 very large discal spots. Iowa. — **immaculata** *suprema*. Jewett, from Ohio, is not striated at all, except traces in the ♂. Larva green, the 2nd and 3rd rings each with *immaculata*. 2 pair of very long red thorns with white tips, the last ring bears one of these thorns, the 6th to 9th rings exhibit short silvery horns; a red lateral stripe is bordered with white beneath. On *Gleditschia* and *Gymnocladus*.

S. isias Bsd. (137 b) is very similar to *hoegei*, but of a dull red-brown colour, a violet tinge at the margin, *isias*. densely dusted with brownish ochreous in the median area, but likewise variable as *hoegei*; the white discal spot may be single or double, in the latter case occasionally extraordinarily enlarged. Hindwing carmine in the disc, dull red-brown in the marginal area. Mexico, also observed in the southern parts of North America. Larva very much like that of *bicolor*, but with shorter horns; on *Parkinsonia*, *Prosopis juliflora* and *Acacia flexicaulis*.

S. isara Dogn. resembles *subangulata*, but it has less pointed forewings and rounder hindwings. The *isara*. median area of the ♂ forewing is reddish-yellow, the base and margin yellow, densely dusted with lilac, all striated brown, the ♀ is more monotonously rusty yellow, but probably variable; transverse lines brown, the anterior one near the base, sinuate, the posterior one from the apex almost straight to the 2nd third of the inner margin, a thick brown discal dot between them. Body rusty yellow with a lilac tinge. Another ♂ is of a deeper rust-brown colour, more uniformly and intensely striated, the ♀ quite ochreous with a slight pink tinge. Very closely allied to *isias*, and DOGNIN presumes it to be a variety. Expanse of wings: ♂ 52, ♀ 65 mm. San Salvador.

S. luteclae Bouv. is an Argentinian species; apex pointed, margin slightly convex; forewing smoke- *luteclae*. brown, with a feeble pink tinge, anterior transverse line and discal line absent; posterior oblique line straight and very obliquely from the apex to the interior quarter of the inner margin, dark brown, bordered with light lilac inwards. Hindwing as forewing. Haute Paraná.

S. modena Dyar (137 b) is a pretty small very light yellow species, occasionally striated rust-brown, *modena*. base and marginal area sometimes with a light lilac pink tinge, transverse line as in *isias* and *hoegei*, 2 white spots in a brownish blotch in the median area. Hindwing light yellow with a red inner-marginal blotch and, separated from it, a cross-vein spot. Mexico.

S. paranensis Bouv. in general resembles *bicolor*, but the forewing is somewhat broader and the apex *paranensis*. of the hindwing rounder. The ground-colour is a darker grey, very finely striated darker, lighter and with a pinkish-red tinge in the median area; discal spot absent in both wings. Hindwing rosy red in the two basal thirds, distal third yellowish-white with a feeble pink tinge; sometimes a posterior transverse line is indicated by a somewhat deeper pink. Expanse of wings: ♂ 51, ♀ 70 mm. Paraná.

S. totoma Schs. Head and thorax of ♂ reddish-grey; abdomen above blackish, beneath grey. Forewing *totoma*. reddish-grey narrowly at the base and at the margin behind the distal line, the median area brown, striated dark brown; the dark grey distal line extends from the costal margin near the apex to the centre of the inner margin; at the cell-end a white spot. Distal and inner margins with dark grey fringe. Hindwing pink, whitish at the distal margin. ♀: forewing of a plain light greyish-brown colour, striated darker, hindwing light pink with a greyish-brown distal margin. Expanse of wings: ♂ 59, ♀ 65 mm. Castro, Paraná.

S. diluta Roths. (137 c). Body reddish yellowish-white above, abdomen with a pink hue above; *diluta*. shape of wings as in *crocata* Bsdv., but longer, with a more pointed apex; reddish light yellow, feebly shaded with greyish-brown in the marginal area, particularly along the blackish-brown distal oblique line extending from the apex to $\frac{2}{3}$ inner margin; the anterior line is quite indistinct, angled in the cell, a feeble blackish-brown cellular spot between them. Hindwing light carmine, turning paler reddish yellowish-white towards the margin. North Argentina. Length of forewing: 32 mm.

S. jucunda Wkr. (= *dimidiata* H.-S., *smithii* Ehrm.). Reddish-brown with a lilac tint, head and under *jucunda*. surface yellowish-white; the black oblique line of the forewing extends from the apex along the median to the

base, above it the finely blackened cross-vein, 3 lilac bands below it. Hindwing yellowish red-brown with white fringe. Brazil.

- jucundoides*. **S. jucundoides** *Bouv.* has somewhat broader forewings than the very similar preceding species; the colour is yellowish, the thorax of a purer yellow, abdomen brownish; hindwing light, without any violettish pink, very finely striated black; the oblique line extends down below the median and, behind the discal spot, it sends a branch to the inner margin, another branch before it to the costa; a small grey spot on the cross-vein. Hindwing with a very feeble postmedian line to the centre of the inner-margin. Venezuela (Merida).
- invalida*. **S. invalida** *Schs.* (137 b). Forewing above dark brown, with a purple tinge, lighter along the distal margin; the distal oblique line extends from the apex to the centre of the inner margin and is bordered lighter distally; discal dot white. Hindwing dark red with yellow fringe. Thorax and 1st abdominal ring orange red, abdomen purple red. Rio de Janeiro. Presumably only a variable form of *crocata*.
- crocata*. **S. crocata** *Bsdv.* (137 c) is a small species like *invalida*, reddish brownish-yellow, the very narrow brown posterior transverse line extends from the apex towards the centre of the inner margin, but it vanishes before, after having formed an obtuse angle inwards below the median. Anterior transverse line quite extinct; the white discal spot is very small, the margin with a faint light pinkish lilac tinge. Hindwing not marked. Brazil.
- pamala*. **S. pamala** *Schs.* (= *tricolor* *Bouv.*). Body yellow above, white beneath; tegulae lilac; forewing brownish lilac at the base and distal margin, median area yellow at the inner and costal margin towards the apex, otherwise lilac with a white discal area broadly bordered with lilac; distal line from the apex to the inner margin near the anal angle slightly striated yellow on the inside. Hindwing light yellow, with a slight reddish tint at the inner margin. Beneath light yellow, costal and distal margins of forewing lilac. Expanse of wings: 35—45 mm. Castro, Paraná.
- tibialis*. **S. tibialis** *Rothsch.* (137 c) has the colour of *pamala* from which it is easily separable by a thorn on the anterior and middle tibiae. Antennae with 27 pectinated and 11 plain segments. Body yellowish, collar, margins of tegulae, base of abdomen, and ventrum pink. Wings chromatic above, border and inner margin tinged with pink, distal oblique line from the apex to $\frac{3}{5}$ inner margin, distally faded. A small white spot in a pink ring at the cell-end. Hindwing quite pink. Paraguay. Length of forewing: 19 mm.
- citrina*. **S. citrina** *Schs.* Head and thorax light yellow; face and forelegs intermixed with some reddish hairs, abdomen white. Forewing light yellow, a fine darker line extends from close below the apex to the inner margin close behind the centre; anterior transverse line very indistinct; the small discal spot is whitish. Hindwing light yellow, whitish basally. Expanse of wings: 70 mm. British Guiana.
- pelota*. **S. pelota** *Schs.* Front body yellow, head, collar and tegulae violet. Abdomen red-brown above, white beneath. Forewing lilac at the base and marginal area, the latter lighter in the centre; the yellow median area striated dark with a large dark lilac shadow at the cell-end and a white cross-vein streak therein. Hindwing reddish-brown. French Guiana.
- roseilinea*. **S. roseilinea** *Schs.* is very different: body and wings white, the latter with a pink basal hue, 2 pink transverse lines, the interior one from the costal margin over the cross-vein, then bending inwards, the exterior one from near the apex behind the centre of the inner margin. Hindwing with a feeble fine pink postmedian line. Costa Rica.
- nettia*. **S. nettia** *Schs.* (137 c). Mesothorax light yellow, the rest of the front body lilac grey, abdomen light red, whitish beneath. Forewing in the basal third and at the margin purple lilac, turning lilac white towards the inner margin, also in the median area above it a large triangular yellow area with its point at the apex, enclosing a purple brown shadow with 1 or 2 white dots at the cell-end, the costal margin above it is reddish orange, and before it in the cell there is a small orange spot; the border between yellow and marginal lilac is undulated, the yellow and lilac areas striated darker. Hindwing yellow, a longitudinal spot before the inner margin, as well as the costal margin are purple red. Expanse of wings: 52 mm. South-West Brazil (Joinville); Amazons.
- wagneri*. **S. wagneri** *Bouv.* resembles *hemirhodia*, but the wings are light yellowish above and beneath, with a feeble pink hue basally and in the distal area, the veins somewhat brighter pink: discal spots and transverse lines absent except traces of a posterior line proceeding close before the apex and extending straight and in an oblique direction to the inner margin. Expanse of wings: 50 mm. Argentina.
- hypoxantha*. **S. hypoxantha** *Rothsch.* (= *flavidorsata* *Dogn.*) (137 d). Collar and abdomen ochreous, thorax and ventrum reddish-brown. Forewing narrow, with a long inner margin, reddish-brown, finely speckled black, with a very feeble interior line and a broad distinct brown exterior line, a large blackish cellular spot between them. Length of forewing: 27—30 mm. Argentina (Tucumán).
- hemirhodia*. **S. hemirhodia** *Rothsch.* (137 d). Thorax brown with a purple tinge, abdomen pinkish ochreous. Forewing dark brown with a pink tinge, more densely strewn with a darker brown, the marginal area shaded with grey, without transverse lines, a small quite indistinct blackish-brown spot at the cell-end. Hindwing yellowish-pink,

margin shaded with brown, with a deeper pink cellular spot. Length of forewing: 25 mm. Argentina (Tucuman).

C. sabulosa *Rothsch.* (137 d). Thorax dark brown, abdomen lighter, ventrum pink; forewing dark or *sabulosa*. loamy brown, densely speckled with blackish; from the apex to $\frac{2}{3}$ inner margin a blackish line, slightly incurved below the middle, the marginal area behind it greyish; anterior transverse line absent; at the cell-end a white often bipartite cellular streak. Hindwing pinkish-brown or claret-coloured, with faint traces of a blackish-brown postmedian line. Forewing 25 mm. Argentina (Tucuman).

S. corrupta *Schs.* Head, collar and tegulae purple slate-coloured, thorax pinkish-brown, abdomen *corrupta*. light reddish-brown. Forewing purple slate-coloured basally, turning pinkish-brown towards the margin, rather densely striated black, less so at the distal margin, without traces of transverse lines. Hindwing light brown, shaded darker at the costal margin, purple red along the inner margin. Expanse of wings: 72 mm. Joinville (Brazil).

S. vinacea *Rothsch.* (137 d). Anterior body reddish ochreous brown, abdomen claret-coloured; forewing *vinacea*. brownish claret-coloured basally and in the marginal area, reddish ochreous in the median area, towards the costal margin almost to the apex; no transverse lines, the whole wing feebly strewn with blackish-brown, no distinct cellular spot. Hindwing claret-coloured, the darkest between the cell-apex and inner margin. Margin almost straight. Length of forewing: 32 mm. South-Eastern Peru.

S. approximans *Schs.* is similar to *vinacea*; body purple above, thorax and base of abdomen ochreous, *approximans*. violettish-white beneath; forewing lilac, striated dark, costal-marginal portion between the apex and median vein brown; inner margin purple, a white dot bordered with purple at the cell-end. Hindwing purple red. South-Eastern Brazil (Joinville).

S. leucantha *Bsd.* has the size of *brevis*; forewing light cinnamon reddish, base and marginal third *leucantha*. whitish pinkish grey, defined by oblique, scarcely darker lines which are often absent, a brown dot at the cell-end. Hindwing the same, with red hair at the inner margin; body coloured like the wings. — Larva green with white small thorns showing black ends and being thicker and somewhat dentate on the 2nd, 3rd and penultimate segments. Brazil.

S. pacifica *Schs.* Front body ochreous, abdomen reddish-white, tinged ochreous dorsally. Forewing *pacifica*. ochreous, finely strewn with dark; basal area lilac as far as the subcostally angled anterior transverse line; a round brown spot at the cell-end; the fine brown distal oblique line from the apex slightly sinuate to the inner margin behind the centre, the marginal area behind it is darkened. Hindwing reddish ochreous, broadly red at the inner margin as far as behind the centre. The ♀ is more densely strewn, the cellular spot indistinct, hindwing darker. Expanse of wings: ♂ 56, ♀ 62 mm. Costa Rica.

S. argyrantha *Bsdl.* (137 d). Body red-brown, tegulae bordered with lilac grey; forewing red-brown, *argyrantha*. striated black, dusted with lilac towards the margin, the border between the two colours extends obliquely from before the apex to the distal third of the inner margin, very concave distally in the lower half. Hindwing copper-brown. Brazil. The yellowish-green larva exhibits thorns similar to polished silver and reverted denticulate horns. On *Gleditschia*.

S. oda *Schs.* Head white, front body reddish-brown, abdomen dark purple lilac above, white beneath. *oda*. Forewing narrow, from 5 rounded to the centre of the inner margin; hindwing long, slightly angled on 5. Forewing dark brown in the basal half with a long reddish brown cell-end spot, lighter brown distally, finely strewn with black, especially at the inner margin, dusted lilac at the distal margin. Hindwing brown, distal margin narrowly dark lilac below 5, with a white basal spot; fringe white. Expanse of wings: 41 mm. French Guiana.

S. crispula *Dogn.* resembles *crocata*, it has more elongated forewings which are marked the same *crispula*. otherwise, but the discal dot is brown and not white. Colour very variable; saffron-coloured, rusty yellow, yellowish brown or violet, always striated brown, partly unicoloured, partly lighter in the inner-marginal halves of both wings; the fine brown transverse lines are partly scarcely indicated, the anterior one distally somewhat convex, the posterior line from close before the apex to the inner margin almost at the anterior one; the discal dot has almost vanished in the ground-colour. Body like wings. Expanse of wings: ♂♂ 39 to 43, ♀♀ 45—52 mm. Argentina (Tucuman).

S. rubicunda *F.* (= *venusta* *Wkr.*) (137 c). ♂ rosy red above at the base and margin, median area and *rubicunda*. body light yellow, hindwing much paler. In the larger ♀ the pink basal and marginal portions are broadly confluent in the inner-marginal half. Hindwing almost white. — **alba** *Gr.* (= *pallida* *Bowles*) is much lighter, *alba*. almost white. The larva has a red head and a light green body granulated white, with 7 darker green longitudinal stripes and a cerise lateral stripe on the 3 last rings; the horns are shorter than in the other species, whitish, black at the ends. On maple, more rarely on oak. Atlantic States.

S. apollinairei *Dogn.* (137 e) is coloured and marked somewhat like *rubicunda* *F.*, but the colours are *apollinairei*. brighter yellow and pinkish carmine. Body yellow, tegulae, legs and ventrum pink. Forewing from the base narrowed at the costal margin to the apex, the distal margin broadly and the inner margin pinkish carmine, the rest of the disc yellow. Hindwing yellow, costal and distal margin finely pink. Described after a ♂ from Colombia (Villavicencio). A couple evidently belonging to this species, from Rio Grande do Sul, e Coll. StGR. (Berlin Museum), shows the red peach-blossom colour still more extensive, the ♀ is quite unicoloured bright

pink. We figure this couple. I presume that *walkeri* Grt. about which I could not ascertain any further particulars is the same, in which case that name would have to be preferred.

- rorerae*. **S. rorerae** Schs. ♂ orange ochreous on the body above, abdomen with small black lateral spots in the basal half, under surface purple pink. Forewing orange ochreous, basal and marginal areas suffused with light greyish pink, strewn with neutral grey behind the cell and in the marginal area; the brown transverse lines are finely undulate-dentate, the anterior one excurved, the posterior one from near the apex incurved to the centre of the inner margin; 2 small white spots at the cell-end. Hindwing orange ochreous with a dark line from the apex to the centre of the inner margin, marginal area suffused with light greyish pink. The ♀ is monotonously cinnamon reddish, more densely striated dark, light pinkish-grey only at the anal angle of the forewing and in the marginal area of the hindwing. Expanse of wings: ♂ 39, ♀ 56 mm. Macas and Guayaquil, Ecuador.
- heiligbrodti*. **S. heiligbrodti** Harvey (137 e) has light grey forewings finely strewn with dark, the posterior one of the two brownish-grey transverse lines is strongly undulate-dentate, the anterior one introangular on the median, a white dot in a grey shadow at the cell-end. Disc of hindwing pinkish carmine with a black central dot, and with a light grey border. Abdomen pinkish subdorsally. — **hubbardi** Dyar is a much darker stone-grey form. Arizona.
- albolineata*. **S. albolineata** G. & R. (= *raspa* Bsdv.) (137 f). The grey ground-colour of the forewing is densely scaled yellow in a variable intensity, with 2 white transverse lines, the interior one from close behind the first third of the costal margin, bent towards the base on the inner-marginal vein, the exterior one from the apex to the centre of the inner margin, with or without a white central dot between them, the veins more or less dusted with white, especially in the median area; the two transverse lines may intersect on vein 2, especially in the ♀. Hindwing carmine with a black central dot and a white bent postmedian line and white fringe. Mexico; also reported from Arizona.
- formosa*. **S. formosa** Dogn. (= *bilineata* Giac. nec *Burm.*) resembles the following species; front body white, the 6 first abdominal rings pinkish ochreous above. Forewing white, scantily striated brown with 2 longitudinal lines, a dark brown one with a leaden lustre along the costal margin, the costa itself reddish ochreous, the second red-brown along the median, the veins around it pink. Hindwing pinkish brown or light brown with pink veins and white fringe. The ♀ is double its size, abdomen white with a carmine transverse line. Argentina (Rio Salado). — f. **inverso-atomosa** Giac. is densely covered with greyish-black striae. La Rioja (Argentina). — **inversa** Giac. (137 f), considered a species by the author, I believe to be merely a form having developed from *inverso-atomosa*, the whole surface of the wings having turned blackish-grey except a white longitudinal band through the cell, the costal margin itself being finely carmine. Hindwing white, smoky at the margin. 1 ♂ from La Rioja. — **inverso-atomosa** Giac. (137 f) of the latter form exhibits the blackish-grey ground-colour tinged somewhat more reddish, and deeper black striae dispersed across the white and dark colour; the veins on the forewing are prominently reddish. Likewise from La Rioja.
- bilineata*. **S. bilineata** *Burm.* is white, the abdomen above with a feeble pink hue. Forewing with a fine blackish-brown line below the costa, and another somewhat broader one below the median extending to the distal margin right below the apex in a slight proximal bow. Hindwing white. Argentina.
- floresi*. **S. floresi** Giac. being unknown to me is probably also merely a form of one of the two preceding species. In the brief description it is placed beside *bilineata*. Forewing whitish-grey, feebly tinged with pink and strewn with grey; the dark longitudinal line has the same shape as in *bilineata* and extends from the base to the apex in a slight bow. Argentina.
- cinerea*. **S. cinerea** Schs. (142 d). ♂ with long and narrow forewings, with a rounded inner margin; hindwing with a produced anal angle. Forewing grey, median area more brownish-grey, the broad dark lines undulate-dentate, the interior one vertical, the exterior one from near the apex to the inner margin near the anal angle; with or without a large white spot at the cell-end. Hindwing grey at the distal margin and anal angle, the rest more brown, the inner margin almost black. Abdomen golden brown with lighter rings. Rio de Janeiro.
- lilacina*. **S. lilacina** Schs. (= *affinis* *Rothsch.*) exactly resembles the Brazilian *cinerea*, the light margin is broader, the genitals very different; the anal tergite terminates in a short sharp hook. It may be the northern representative of *cinerea* in Venezuela, the Guianas, Amazons, and Peru, but the genitals are rather too different; the nomenclatural type has a more ochreous collar and rounder hindwings, whilst the ♀ shows the marginal area in both wings only half as broad as in — **photophila** *Rothsch.* (142 d), from Surinam and the Amazons. Here the margin of the hindwing is straight or even somewhat concave, the mesothorax somewhat less yellow; ground-colour more pinkish-brown or also olive, forewing without or with a white cellular spot which may also be double, as in the specimen figured from the Berlin Museum from S. Paulo de Olivença. The ♀ is darker, the body less bright ochreous.
- surrotunda*. **S. surrotunda** Dyar (142 c) may also be merely the northernmost representative of *cinerea*, from Mexico. Wings much rounder, distinctly pinkish-brown, the lighter marginal area broad, the transverse lines bordering on the darkened median area much less distinct and scarcely dentate. Mesothorax scarcely yellow, the blackish abdomen with narrow ochreous rings. West Mexico (Colima).

S. subfumata Schs. (137 f) is quite different. Head and thorax light brown with a blackish-brown dorsal *subfumata*. line on the prothorax and mesothorax; abdomen bright pinkish earmine above, brown beneath. Forewing light brown with fine blackish-brown transverse lines, the anterior one undulate-dentate with a short transverse line in the cell behind it, and a black dot at the cell-end; the posterior line is reversely undulate-dentate, extending from a little before the apex to the submedian and from there excurved to the second third of the inner margin; above the submedian both the lines are connected by a transverse line; a feeble curved median shadow extends between the two lines from the centre of the costal margin to the centre of the inner margin; a subterminal row of irregular brown spots. The inner-marginal portion of the light brown hindwing is somewhat darker, the subterminal spots are more distinct, an undulate postmedian line is before them. The costal margin of the long narrow hindwing is very convex. South-Eastern Brazil.

S. molina Stoll (= *simulatis* Grt. & Rob., *grandis* Grt. & Rob., *agenor* Bouv., *propinqua* Bouv.) (142 c) *molina*. differs from all the other species in the notched distal margin, which is much less prominent in the ♀. Colouring variable, lighter or darker reddish yellowish-brown, more or less distinctly striated darker. Forewing with 2 dark transverse lines and a faint shadow at the cell-end; the marginal area behind the distal line is slightly darker, especially in the ♂ tinged with violettish-white below the angle on 4. Disc of hindwing pinkish earmine with a thick black central spot. Widely distributed from Mexico to Brazil. — The larva is stout, raised on the 3rd and penultimate segments, green, with a yellow lateral line bordered with red above, and short yellow, red-tipped horns; it lives on species of Inga and Cassia. — **petersii** Pack. is a questionable form or perhaps *petersii*. species unknown to me; forewing reddish-brown with numerous dark striae, an oblique postmedian line bordered with light outside, with dark inside, and extending from the apex to the centre of the inner margin; disc of hindwing darker earmine, the abdomen is said to be earmine, too. Larva different from that of *molina*: with long dorsal horns on the 2nd and 3rd segments, conical dorsal tubercles on the 4th to 10th, also on the 1st segment, and with a broader anal plate with yellow tubercles. It lives on Mimosa. From Novo Friburgo.

4. Genus: **Neorcarnegia** gen. nov.

Separated from *Syssphinx* by the peculiar habitus; ♂ small with very pointed forewings with a concave distal margin, and a caudiformly prolonged anal angle of the hindwing, the ♀ very stout, both sexes with a great number of vitreous spots on both wings. Structurally also somewhat different; the head is still more hidden and quite flatly pressed on the chest. The cross-vein of the forewing is very oblique and angular, vein 5 removed down almost to the centre of the cross-vein, and 6 from the upper cell-angle, the cell much longer in both wings than in *Syssphinx*. Only 1 species:

N. basirei Sch. (142 f). Unmistakable owing to the numerous vitreous spots on the light ochreolate *basirei*. forewing with a darkened median area. Hindwing more rust-brown at the margin; small yellow hair-tufts at the base of the antennae, above the eyes, and on the metathorax. Anterior thighs pink. Brazil. Nothing seems to be known about the development.

5. Genus: **Anisota** Hbn.

Extraordinarily similar to *Syssphinx*; head somewhat better visible. Wings in general somewhat shorter, narrowly triangular. The ♂ antennae are pectinated as far as a little behind the middle and bear 15 pairs of pinnae, 17—18 pairs in *Syssphinx*. The ♀ antennae are plain, filiform. Chiefly distributed in North America.

A. stigma Fabr. is dark reddish ochreous on the body and wings, the disc of the wings not transparent, *stigma*. base and marginal area with a lilac tinge; anterior transverse line quite indistinct, posterior line dark, sometimes slightly sinuate, the large white discal spot round or triangular. Forewing and distal margin of hindwing striated darker. Larva brown, granulated white, with reddish subdorsal and lateral stripes, cerise head, and a long thin horn on the 2nd segment. On oak and hazel. Widely distributed in the Atlantic States.

A. senatoria Abb. & Sm. exhibits distinctly triangular hindwings in the ♂, distal margin not convex *senatoria*. with a slightly produced anal angle; smaller on the whole than *stigma*, the wings less striated; posterior transverse line very strong, broad and distinct also on the hindwing. The ♀ is lighter, the discal spot smaller. Larva with a black head, blackish-brown body with 8 dark ochreous longitudinal stripes which are slightly undulate; the horns are black. On oak, birch and Rubus, often destructive to oaks. Atlantic States.

A. leucostygma Bsd. (142 f). Only the ♀ type (in Coll. PHILIPON) was hitherto known. Prof. BOUVIER had *leucostygma*. the kindness to send me detailed statements and a sketch of the type. Accordingly, I consider for the present a bred couple from Mexico, which I owe to the kindness of DAMPF and which is also reproduced in our figure, to be this species, although the ♀ is not quite the same as the type. The ♂ is rusty yellow on its body, with a somewhat more olive thorax, forewing olive brown, somewhat lighter and with a slight inclination to lilac at the

margin; the feeble smoky grey postmedian line is near the margin and almost parallel to it, with a bend towards the apex below 8; discal spot white, hindwing cinnamon-brown. The larger ♀ is of a much duller brownish colour and scantily scaled, the postmedian line broad, indistinct. Hindwing without markings. The female type of *leucostygma* lacks the bend of the postmedian line below the costal margin to the apex, it is about 3 mm distant from it, and the hindwing exhibits a distinct transverse line from below the apex straight to the first third of the inner margin. DAMPF who bred the species on oaks from larvae occurring destructively in the State of Tamaulipas will supply an exhaustive description.

consularis. **A. consularis** Dyar (142 f) is very similar to *senatoria*. Body brownish ochreous, wings dark purple brown, behind the round white discal spot a faintly diaphanous area; marginal area more violettish-grey. Hindwing rounder than in *senatoria*, not angular, posterior transverse line more indistinct. The ♀ is of a duller yellowish brown, basal and marginal areas scarcely darker, speckled darker, the white discal dot small. Larva reddish flesh-coloured or reddish brown, granulated white, with black longitudinal bands, the dorsal and stigmatal ones darker and more distinct, bordered with white beneath, horns black. On oaks. Florida.

virginiensis. **A. virginiensis** Dru. (= *astymone* Oliv., *pellucida* Abb. & Sm.) (142 g). ♂ with a large hyaline area behind the discal spot, the white spot at the cell-end very large; deep purple brown, somewhat lighter in the narrow marginal area. ♀ thinly scaled, lighter brown, base and margin with a feeble lilac tinge, scarcely speckled. Larva as in *stigma*, but the head is green, the body more greenish, the stripes more pink; on oaks. Atlantic States.

oslari. **A. oslari** Rothsch. (= *skinneri* Biederm., *neomexicana* Brehme) has the same shape as *virginiensis*, the body deep ochreous; forewing reddish-brown with a silvery white discal spot; a narrow bluish band 4 mm distant from the distal margin and parallel with it. Hindwing deep purple brown. The ♀ is larger than the ♂ and lighter. Head, prothorax, and abdomen ochreous, mesothorax and ventrum more loamy reddish-yellow. Forewing above the same, base and posterior transverse line very feebly grey; stigma white, round; wings not striated darker, margin straighter, anal angle less round than in *stigma*. Hindwing with a slight reddish hue, without distinct lines, costal margin longer than inner margin. Expanse of wings: ♂ 53, ♀ 71 mm. Larva reddish-brown, at last dull red, young larva without horns, only with dark dots where they grow later on; it lives on black oak.

dissimilis. **A. dissimilis** Bsd. (= *suprema* H. Edw.) (142 g). The ♂ forewing is red-brown, with black veins, an oblique black posterior transverse line and a large white discal spot; hindwing black. Thorax reddish-yellow, abdomen black with a reddish-yellow anus. The ♀ forewing light cinnamon reddish like the thorax, marginal area lighter, with distinct darker veins, a large round white cell-end spot, the feebly curved greyish-black postmedian line somewhat white-scaled distally. Hindwing dark reddish-grey, with black veins, a broad black antemedian shadowy band. Mexico, widely distributed.

assimilis. **A. assimilis** Drc. (142 g) is allied to *dissimilis*, but the body, forewings and hindwings monotonously reddish-brown, the hindwing somewhat darker, the white discal spot of the forewing much less distinct, the veins not darker. Only the ♂ is known, apparently very rare and hitherto only reported from Chihuahua.

Eacles tricolor Wkr. and *Eacles suffusa* Wkr. have remained unknown, nor could Mr. SCHAUS supply any information about them.

Subfamily: Oxytenidae Jord.

This subfamily and the following one are entirely unlike the usual Saturnid type and frequently resemble partly Geometrid genera, such as the extremely variable *Oxydia*, or *Urapteryx*, partly certain Uranid forms as found in the African and Indo-Australian Regions. We treat these insects as a deviating branch of the *Saturnidae*, whilst JORDAN, in his most excellent and exhaustive treatise*), prefers to raise it to the rank of a family. Anybody that is particularly interested in this group cannot do without studying this monography. As a matter of course, we cannot enter into the finer anatomical details, especially the genital differences, except in a most brief way and we therefore refer expressly to the said work the arrangement of which we observe in the following. The species which, according to JORDAN, exhibit certain antique features are chiefly separated from the other *Saturnioidae* by a mostly rather strong convolvent tongue, the antennal shaft being scaled as far as the tip, the antennal pinnae (being developed in both sexes) arising on the ventral side, and the well developed precostal branch on the hindwing; the palpi are relatively long. The larvae living on Rubiaceae are very peculiar and quite different from the other *Saturnidae*; resting contracted on leaves they resemble the droppings of birds. The 3rd segment is strongly expanded anteriorly and beneath and exhibits 2 ocelli, the penultimate segment bears a curved horn which is often bipartite at the end. The pupa spins itself with a few threads in a convolute leaf.

*) JORDAN in *Novitates Zoologicae* XXXI. p. 235 (1924).

1. Genus: **Asthenidia** Westw.

About 1 dozen of white or yellowish forms similar to *Geometridae* or *Uranidae*, with short-tailed hindwings, all of which are very similar. The genus is particularly characterized by vein 10 of the forewing only arising shortly before the apex from 8, and the hindwing being tailed between veins 4 and 5. Proboscis relatively feebly developed, the last palpal joint short. Cell of forewing very short. The larva resembles a small green *Sphingid* larva, its 3rd segment is not so strongly expanded anteriorly and beneath.

Type: *podaliriaria* Westw.

A. podaliriaria Westw. (121 a) differs from all the other species of this genus in the greyish-black apex of the forewing. Apparently only known hitherto from Brazil (Rio de Janeiro), but probably with a wider range. The ♀ has not yet been described. *podaliriaria*.

A. amphira Drc. (121 a) is one of the largest species, the transverse lines distinctly leaden grey, not brownish as in all the others, the distal band of the hindwing broader than in the very similar, though smaller *geometraria*. Known from Colombia, Ecuador, Bolivia, and Peru. *amphira*.

A. transversaria Drc. (121 a) is somewhat smaller than *amphira*, more chalky white, the transverse lines with a reddish-brown tinge, the tail shorter and without the black vein 5 of *amphira*, the black spots therein very large. JORDAN divided the collective species into 3 geographical forms which, however, are only to be separated by genital differences. In the nomenclatural form from Panama and probably West Colombia the upper appendage of the clasper is shortened with an apical projection, whilst in — **salax** Jord., from Nicaragua and Costa Rica, the upper appendage of the clasper is longer, not divided, and only with traces of a projection, and in — **columbiana** Jord. the same appendage is short and ends in 2 bent prongs, one of which bears a third plain or forked appendage on its inside. The latter form is known from Muzo and Bogota. *transversaria*.

A. terminalis Jord. is exactly like *transversaria*, but the forewing shows a fine black marginal line interrupted by the veins; the subterminal band of the hindwing, which is only indicated by grey in *transversaria*, is much more distinct and blacker, the yellow spot in the tail is reduced and more reddish-brown, the tail parted by the fine brown radial vein. Genitally very different. Ecuador and Colombia. *terminalis*.

A. geometraria Fldr. (121 a) is likewise very similar, the subterminal band of the hindwing broadly brownish-grey, the postdiscal band of the forewing is interrupted above the inner margin, forming partly zigzag-shaped points on the hindwing, where the fringe is black from the tail to the anterior angle, the upper spot on the tail being spotted red-brown distally. Widely distributed: Guiana, Colombia, Ecuador, Amazons, Peru, and Bolivia. *geometraria*.

A. celata Jord. (= *geometraria* Drc. nec Fldr.) is externally exactly like *geometraria*, the transverse bands are finer, the postdiscal one of the forewing scarcely interrupted, more regularly dentate on the hindwing, traces of a brown marginal line from the tail to the anal angle. The genitals are very different. Only known from the Amazons and Ecuador. *celata*.

A. paulina Jord. (121 a) was described after a bad specimen; as *geometraria*, with thin bands, the postdiscal one broadly interrupted on the forewing. Genital apparatus very different from all the others. South-Eastern Brazil (São Paulo); a ♀ from Sa. Catharina, in the Berlin Museum, shows a somewhat yellowish colour. *paulina*.

A. diffissa Jord. (121 a). The postdiscal band of the forewing is not interrupted, the antemedian band of the hindwing deeply forked analwards, the postdiscal one very distinctly undulate-dentate analwards, the anteterminal band mostly more remote from the margin. In distinction from all the other forms known there is on the 8th sternit on each side a very long bent pointed appendage which varies geographically. In the nomenclatural form the apex of these appendages is bent downwards ventrally. It flies in Ecuador, the Amazons, and North Peru. — In **fortis** Jord., from East Peru, it is longer, and bent sideways and upwards, in — **inca** Jord. like that of the nomenclatural form, but more bent; South-Eastern Peru, Cuzco. — In **tridens** Jord. it is still more bent and slightly twirled. South-Eastern Peru (Yahuar Mayo, Carabaya). *diffissa*, *fortis*, *inca*, *tridens*.

A. stricturaria Hbn. (= *machaonaria* Guér., *strigaria* Hbn.) (121 b) is easily distinguished by the short cellular streak of the other species being prolonged into a band extending to the inner margin; the two distal bands are nearer together, the subterminal line is absent, fringe black; the hindwing shows a fine third line between the two bands; the upper tail-spot is bordered with brown inside, not outside. Guiana, Amazons; in the Berlin Museum from São Paulo. *stricturaria*.

A. spinicauda Jord. entirely resembles *stricturaria*, but on the 8th abdominal tergite there is on each side at the margin, which is plain in *stricturaria*, a sharply pointed appendage the apex of which terminates into a fine thorn. French Guiana, Amazons. *spinicauda*.

- lactucina*. **A. lactucina** Cr. (= *lactucinaria* Hbn.) (121 b) is mostly of a yellowish or Isabel-coloured tinge, rarely all white, at once separable from all the other species by the more or less extensive brownish speckles and by the fine undulately notched double postdiscal lines. Larva green with a small black ocellus on each side of the 3rd segment, both connected by a brown streak; anal segment and horn brown, the latter with a white line running down; it lives on *Ourouparia guianensis*, Venezuela, Guiana, Amazons, Matto Grosso, Ecuador, Bolivia, Paraguay.
- buckleyi*. **A. buckleyi** Drc. (121 b) is the largest species with creamy wings, a characteristic marking, the ante-median band of the forewing being entirely absent. The nomenclatural form from Colombia, Peru, Bolivia, Guiana, and the Central Amazons exhibits a fine submarginal line beneath, which may be entirely absent on *paraensis*. the hindwing, whereas in — **paraensis** Jord., from the lower Amazons (Pará), it is almost 3 mm broad, especially in the middle.

2. Genus: **Oxytenis** Hbn.

Anatomical structure almost the same as that of the preceding genus, but the wings are either entire (in the ♀♀ invariably so), or with dents or lobes at the distal margin, occasionally also with a short caudiform projection, but never at vein 5, but always on 6. The species, particularly the ♀♀, resemble the Geometrid genus *Oxydia* in their colouring and scheme of markings; the sexual dimorphism is mostly very distinct, both sexes exhibit a small heap of erect scales at the lower cell-end. Neuration almost the same as in *Asthenidia*, though the short cell is somewhat broader. The 3rd segment of the larva is expanded on each side into a broad lobe extending forward and downward; the flexible caudal horn is bent S-like. The numerous species are partly so very similar that they can only be distinguished by the genitals.

Type: *modestia* Cr.

- modestia*. **O. modestia** Cr. (= *honesta* Cr., *bimaculatus* Doum., *attacina* Wkr., *lonomica* Drc.) (121 c) is the most common and widely distributed species. Wings entire, only the apex of the forewing slightly falciform. Colouring and marking extremely variable, reddish or more yellowish brown, especially the ♂♂ with a more or less intense lilac grey tinge, more distinctly marked or also not marked at all, mostly with a line extending from the apex of the forewing to the centre of the inner margin on the hindwing, behind it especially on the hindwing a series of lighter crescents; blackish clouds of variable intensity behind and before the line. The larva is green, with yellow and white rings around the black ocelli; a large white, brown-spotted saddle-spot in the centre of the dorsum, and a purple brown spot before the blackish-brown horn. Hitherto observed from Guatemala to Bolivia and South-Eastern Brazil.
- albilunulata*. **O. albilunulata** Schs. (121 c). Ochreous or chestnut brown, the ♀ darker cinnamon-brown, marked like *modestia*; a broad blackish nebulous stripe proximally to the oblique line, a series of fine white crescents behind it; a black fine crescentiform line on the hindwing is more remote from the oblique line and not filled with whitish. West Ecuador, Panama.
- mirabilis*. **O. mirabilis** Cr. (121 c). Forewing dentate, with a lobate projection above the centre; loamy brown or red-brown, with an oblique line from the apex to the inner margin of the hindwing, but always remaining near the margin on the forewing; more or less covered with blackish clouds; a fine blackish line distally bordered with whitish is behind the oblique line. Disc of hindwing more or less tinged whitish, in the centre with a fine darker line forming high arches analwards, which are distally bordered with whitish; small black spots behind it. Guiana.
- sobrina*. **O. sobrina** Jord. is externally almost exactly like *mirabilis*, but below the apex of the hindwing there is a slight concavity; the disc of the forewing exhibits still larger blackish clouds. The species can only be discriminated by the genital apparatus: the lobes of the 8th sternit are narrower than in *mirabilis*, still narrower towards the apex. It may be a geographical form of *mirabilis* from Peru.
- naemia*. **O. naemia** Drc. (121 d) is likewise difficult to separate from *mirabilis*, but there are 2 low incisions below the apex of the hindwing. By the genital apparatus it is to be distinguished: the lobes of the anal tergite are shorter than in *mirabilis*. The commonest and most widely distributed species from Costa Rica to Paraguay. Several geographical forms: the nomenclatural type from Peru, Ecuador, and the Amazons; the apical appendage of the penis-cover forms a frontally bent hook with a broad flat point. — In **aravaca** Jord., from Venezuela and Guiana, the apical appendage of the penis-cover is compressed, and in the northernmost form — **orecta** Jord. (121 d), from Costa Rica, Panama, and Colombia, it is bent obliquely analward and laterally, more or less twirled, with a dentate posterior end. The black oblique line is mostly very distinct and stout in the latter form.

O. leda Drc. (121 d). Wings narrower than in *naemia*, lobe of forewing broader, the two incisions below *leda*. the apex of the hindwing deeper, the distal margin below it forming a straight line. Otherwise coloured and marked as the preceding species. Genitally different: the lobes of the 8th sternit longer etc. Peru and Amazons.

O. erosa Jord. (121 d). Exterior scarcely different from *leda*, but genitally distinctly separated by the *erosa*. apically narrowed triangular lobes of the 8th sternit etc. Guiana.

O. nubila Jord. likewise shows two indentures below the apex of the hindwing, the corners between *nubila*. them are sharper than in *naemia*. More unicoloured loamy brown, marked like the other species, the lowest of the 3 black dots at the anal angle of the forewings is larger than the others. Discernible by the spoon-shaped lobe of the 8th sternit. 2 geographical forms: the nomenclatural type from Colombia is intensely marked greyish-white, the 3 anal dots on the forewing are large. The lobes of the 8th sternit are short, their interior surfaces deeply concave. — **acuta** Jord. (121 e), from Nicaragua, is more unicoloured, the 3 anal dots very *acuta*. small or extinct except the lowest. The lobes of the 8th sternit are apically narrower, the interior surface less concave.

O. bicornis Jord. is externally not separable from *leda*, but genitally quite different: the 8th sternit is *bicornis*. extended into a long bent thorn on each side etc. South-Eastern Brazil (Santos; Castro).

O. peregrina Cr. (121 e). Forewing more uniformly dentate, the lobe much less projecting in the centre; *peregrina*. hindwing with 2 deep indentures below the apex and a short tail below it; distal margin below it straight as far as the somewhat lobate anal angle. Ground-colour deep brown, mostly lighter basally and at the margin before which, in the lower half, there are oval loamy brownish spots; forewing often dusted bluish-white, like spots. The ♀ is mostly lighter, more loamy brownish, more distinctly marked. Known from Guiana, the Amazons, and Peru.

O. epiphaea Jord. (121 e). Wings shaped as in *peregrina*, but the forewing is without the small dent *epiphaea*. below the apex and that above the anal angle. Monotonously dark chocolate. The ♂ antennae are longer pectinated than in *peregrina*, the lobes of the 8th sternit truncate, its corners extended into long thin bent thorns (triangular with a rounded apex in *peregrina*). Peru.

O. plettina Jord. is somewhat smaller than *peregrina*, otherwise of the same exterior; the pointed lateral *plettina*. appendages of the 8th sternit are proximally broader than in *epiphaea* and bent backward distally. Ecuador.

O. beprea Drc. (= *mirabilis* Drc. nec Cr.) (121 e) is a smaller species; apex of forewing much sharper *beprea*. pointed, the margin very slightly dentate or quite smooth, tail of hindwing less pointed than in the preceding species. Colouring most variable, loamy yellowish, wood-brown, or dark brown, markings very similar to those of the preceding species. Antennal dents longer than in *peregrina*. The lateral appendages of the 8th sternit as in *plettina*. Panama, British Honduras.

O. angulata Cr. (= *harpago* Hbn., *zerbina* Cr.) (122 b) is also of a most variable colouring, and size. *angulata*. Loamy brown or dark sepia-brown above, the dark oblique line of the preceding species is absent in the ♂, whilst it is more distinct in the light yellowish or reddish-brown ♀. The 8th sternit with a double excision and rounded sides, the middle lobe mostly reduced to a dentiform appendage. The black larva with rusty yellowish and whitish-grey spots resembles bird's droppings, the metathoracic lobes are dingy tan-coloured; on *Randia formosa*. Guiana, Venezuela, Amazons, Para.

O. ferruginea Wkr. (= *zerbina* Wkr. nec Cr.) (122 b) is exactly like *angulata* and just as variable, but the *ferruginea*. sides of the 10th tergite are much deeper indented, scarcely so in *angulata*, etc. Larva similar to that of *angulata*. Panama to Venezuela, Bolivia and Matto Grosso.

O. gigantea Drc. Contours of wings similar as in *beprea*, but much larger; its colour varies between *gigantea*. ochreous and dark brown, dusted with greyish-white, oblique line double, filled with whitish. The 8th sternit is laterally extended into long pointed horns. Ecuador and Peru.

O. spadix Jord. is allied with *gigantea*, to be separated by longer antennal dents of the ♂. Yellowish- *spadix*. ochreous above, shaded with purple red and dusted with greyish-white, the double oblique line stronger than in *gigantea*, the interior line stronger than the exterior line. In the only specimen known hitherto, described from the Colombian Cordilleras (Alto de las Cruces), the genital organ differs from that of *gigantea*. Length of forewing: 36 mm.

3. Genus: **Homoeopteryx** Jord. (Fldr.)

Separated from the preceding genera by the uppermost subcostal branch arising from the cell and 6 being stalked with 7 on the hindwing. Margin entire, apex sickle-shaped. The small heap of scales in the lower cell-angle is absent. Antennal pectinations longer than in *Oxytenis*. 5 species are known.

Type: *malecena* Drc.

- malecena.* **H. malecena** *Drc.* (122 b). Upper surface loamy brownish or reddish-brown, the ♀ greyer with a brown oblique line from the apex of the forewing to the proximal third of the inner margin of the hindwing, behind which a crescentiform line follows, divergent towards the inner margin; darker spots are often before the margin, black dots on the hindwing. Two races: in the nomenclatural form from Panama the oblique line is fine, the lobes of the anal tergite bent towards each other apicad. — In **prona** *Jord.* the oblique line is much thicker, the lobes of the anal tergite very feebly bent. Trinidad and British Guiana.
- major.* **H. major** *Jord.* is larger than the preceding species, more brownish wood-coloured above, the oblique line bordered with greenish-yellow inwards. Lobes of the anal tergite more obtuse, broader basad, narrower apicad. The ♀ is more yellowish ochreous, with a red-brown tint. Peru.
- syssauroides.* **H. syssauroides** *Fldr.* Only the bad type without its antennae and abdomen is known. Dark red-brown above with yellowish ochreous submarginal clouds; oblique line dark brown, narrowly bordered with grey outside, and removed farther to the margin than in the preceding forms, terminating behind the centre of the inner margin of the forewing and in the centre of the inner margin of the hindwing. Brazil.
- elegans.* **H. elegans** *Jord.*, described after 1 ♂ from Peru, is shaded with yellowish red-brown above, with a dark red-brown oblique line and a large round deep brown spot at the lower cell-angle; basal area and large oval subterminal spots remain yellowish-white. Length of forewing: 39 mm.
- divisa.* **H. divisa** *Jord.* Forewing dark red-brown as far as the oblique line, distally to it reddish-yellow, dusted with reddish cinnamon colour; the line itself cinnamon red, outside a fine grey line and distally to it a dull dark brown one; lighter roundish submarginal spots rather inconspicuous, proximally defined by crescents which are nearer to the oblique line than in the other species. Length of forewing: 34 mm. Bolivia.

Subfamily: Cercophanidae *Jord.*

As in the preceding branch of the large Saturnioid family, which has evidently split off already at very early epochs and has further developed separately, this subfamily has retained an ancient characteristic separating these insects from the Saturniid type: the costal of the hindwing is connected with the cell by an oblique bar as in the *Eupterotidae* and *Bombycidae*. The family is divided into 2 subordinate groups:

A. Cercophaninae *Jord.*

Proboscis absent, last joint of palpus distinct, frons long-haired, antennae long-combed in both sexes. The very peculiar larvae are only known of two species; the 3 first rings are increasingly thickened, the strongest 4th ring is extended into a sharp point turned anteriorly and projecting hood-like, into which the light lateral streak terminates, which, on the opposite side, terminates into an equally sharp anal point. The few species of this subordinate group are confined to the southernmost extremity of South America. Chile.

1. Genus: **Cercophana** *Fldr.*

This genus and the following one are closely allied. The proximal antennal segments beneath not carinated, last palpal joint somewhat shorter than in the following genus; antennae of ♂ much longer pectinated than in the ♀. Only two species, one being most variable.

Type: *frauenfeldi* *Fldr.*

- frauenfeldi.* **C. frauenfeldi** *Fldr.* (122 c). Forewing yellowish greyish-brown, with a red-brown tint towards the margin, 3 dentate transverse lines, the antemedian line projecting quadrangulately below the cell, a dark spot behind it in the lower cell-angle, though it may also be absent; the subterminal line forms high arches, the ends of which are punctiformly thickened inwards on the veins. Hindwings tailed. The scantily scaled ♀ shows a creamy yellowish ground-colour, with very faint brownish lines, the postmedian line scarcely dentate; hindwing almost entirely rounded. Larva of the shape described above, green, the lateral stripe yellowish, roundish pink spots on the first and 5th and 6th segments above; each segment laterally with one long black, apically thickened hair. The very lazy larva lives on *Cryptocarya peumus* in November and pupates in an oval cocoon which is open at its upper end according to JORDAN, closed on both sides according to JZQUIERDO. Chile.
- venusta.* **C. venusta** *Wkr.* (= *aristoteliae* *Phil.*, *rufescens* *Phil.*, *daphnea* *M. & W.*) (122 c). An uncommonly variable species of a ground-colour varying between yellow maize-colour and chestnut-red, to which variations the numerous individual names refer, often suffused with rosy-reddish, with a round white central spot bordered with brown, and a flatly curved brown postmedian line and a notched subterminal line behind it, which is often absent, sometimes all the lines are extinct. Extremely red-brown specimens may be named: — **vulpes**.

Btlr. The larva is larger than that of *frauenfeldi*, very similar to it, but the lateral line on the thoracal segments white, light blue above, blue, black and orange on the 4th segment, yellow posteriorly, turning pink beneath; the oval pink spots on the dorsum are absent. It lives on *Maytenus chilensis* and *Aristotelia maqui*. The pear-shaped cocoon is grey. Chile.

2. Genus: **Neocercophana** *Izquierdo*.

Extremely similar to the preceding genus, separated by the antennal shaft being sharply carinated below and a longer last palpal joint. Only 1 species:

N. philippii *Izquierdo* (122 d). Dark brown above, duller in the ♀, strewn with greyish-white in the *philippii*. basal third, with 2 whitish antemedian and postmedian transverse lines. The basal two thirds of the hindwing are red-brown. Larva unknown; the spindle-shaped cocoon is open on both sides, the apical thread freely suspended on a twig. It lives on *Hydrangea scandens*. Chile.

3. Genus: **Microdulia** *Jord.*

Characterized by the tailless wings in both sexes. Likewise only 1 species:

M. mirabilis *Rothsch.* (122 d). The ♂ is dark rust-brown above with a darker discal line and a white *mirabilis*. spot at the cell-end; hindwing orange with a dark marginal band, somewhat angular. The ♀ is lighter, more yellowish, the forewing besides with an antemedian line. Fringe speckled yellowish-white in both sexes. Chile.

B. Janiodinae *Jord.*

Separated from the preceding subordinate family by the strong proboscis. Only 1 genus the species of which are very similar to *Eupterotidae*, to which they are allied in a certain way.

4. Genus: **Janiodes** *Jord.*

A few brown or grey, often very variable species with broad wings, rather long palpi, the last joint of which is porrect. Proboscis strong. Antennal shaft carinated below, with long and loose pectinations. Hitherto only known from the Bolivian and Colombian Andes.

Type: *J. laverna* *Drc.*

J. laverna *Drc.* (= *pulverosa* *Strd.*) (122 e) is the largest and most variable species, reddish loamy *laverna*. yellowish above in all shades to blackish sepia-brown, strewn with greyish-white, chiefly on the veins, with 2 small or very large black cell-end spots, 2 antemedian transverse lines and 2 postmedian ones which may be either notched or without notches, the subterminal line being the most notched. The ♀ is more orange reddish. In the form — **nigropuncta** *Drc.* (= *pauperata* *Strd.*, *desquamata* *Strd.*, *macromacula* *Strd.*, *duplinota* *Strd.*, *nigro-puncta*. *Strd.*) (122 e) the interior postmedian line is almost straight. Colombia, Ecuador, Bolivia.

J. dognini *Jord.* Greyish sand-colour above, strewn with a bluish-white of a silvery lustre, with 2 dark *dognini*. dots in the cell-angles with double antemedian and postmedian transverse lines, the interior postmedian line incurved near the lower cell-angle, the exterior antemedian line in the cell. Only 1 ♂ is known, from Colombia (Mt. Tolima).

J. ecuadorensis *Dogn.* (= *monacharia* *Maass.*) (122 d). Dark brown, with a red-brown tint in the basal *ecuadorensis*. and marginal areas, similarly marked as the preceding species, the interior antemedian line often bordered with yellowish ochre, the postmedian double line filled with grey, often a reddish-yellow spot behind it above the anal angle. — **flexuosa** *Dogn.* is somewhat larger, with a broad yellowish subbasal band, a more undulated *flexuosa*. discal line and a yellowish loam-coloured marginal area. Colombia, Ecuador, Peru.

J. russea *Dogn.* is very similar to *ecuadorensis*, more rusty brown, especially the subbasal area rusty *russea*. yellowish, at once recognizable by the very broad and straight double lines; no cell-end dots; the undulate-dentate subterminal line is very fine. Colombia.

J. virgata *Jord.* was founded upon but 1 ♀ without antennae and abdomen. Sandy brown above, *virgata*. strewn with whitish, recognizable by the very broad and straight double lines; no cell-end spots; the undulate-dentate subterminal line is very fine. Colombia.

J. bethulia *Drc.* resembles *ecuadorensis*, some places are slightly tinted cinnamon-reddish, the antemedian *bethulia*. lines are less strongly curved, 3 brown dots in the cell-end, the postmedian line very straight, passing close at the lower cell-angle, the subterminal undulate line very distinct; basal and marginal areas often of a dingy yellowish ochreous colour. Peru.

Additions.

P. 716, line 4 from above, add to the synonyms: *hesperus* auct.

P. 719, line 5 from above, add to **maurus** the synonym: (= *maurusius* *Schreit.*). SCHREITER describes the larva to be sea-green with violettish-white girdles and white hair; it lives on a tree-like Euphorbiacea (*Croton* spec.) and is very much infested by Ichneumonidae (*Eremotylus* spec.).

P. 719, line 18 from above, add to **maurusius** the synonym: (= *maurus* *Schreit.*). According to SCHREITER, the larva is black with yellow girdles, set with fine white hair. It lives polyphagously on Euphorbiaceae (*Sapium haematospersum*), Anacardiaceae (*Duvana* spec.), and Bignoninaceae (*Jacaranda acutifolia*). It is likewise decimated by the said Ichneumonid. Two generations.

P. 719, line 26 from below, add to **tucumani**: SCHREITER describes the larva to be bright green with white girdles and short black branched thorns. It lives monophagously on *Eupatorium buniifolium* and pupates in an ovoid yellowish white case and frequently receives an Ichneumonid (*Trachysphyrus* spec.).

P. 719, line 17 from below, add to **condor**: SCHREITER found the species in Tucuman (Argentina), at altitudes of 1500—2000 m in a form differing considerably from the Peruvian type: — **schreiteri** *f. n.* Somewhat smaller and much lighter, of a more pinkish-brown ground-colour, the costal-marginal area in both wings remarkably lighter violettish-white, with intensely black veins, a much narrower median area, much shorter and broader hyaline spots without the extraordinarily long ramifications that are shown in our figure of the type; the postmedian line is more pointedly notched, the subterminal area is broader, the proximal portion of the marginal area much lighter. Larva green with white girdles, on each girdle with 6 ramified thorns. It lives on *Baccharis sculpta* (Compositae) and pupates in a dingy white ovoid case. After a pupal stage of 7 or 8 months the imago emerges in November and December.

P. 725, line 26 from above, to **vitellina** add the synonym: (= *canella* *Schreit.*). Judging from the figure of *canella* supplied by SCHREITER (Univ. Nac. de Tucumán, 1925), it is undoubtedly the yellow form of *joinvillea* which he found in Argentina, quite different from *canella* with its broad and obtuse wings. The larva is green with 2 orange red dorsal hair-tufts on each segment, the central hair longer and black, with 2 rows of much shorter red-brown hair-tufts on each side, and with red stigmata. It lives on the Lauracea *Phoebe porphyria* and pupates in an exterior widely reticulated and interior narrowly reticulated web.

P. 743, line 15 from above: **A. superba** *Burm.* is to be cancelled, and on p. 767, line 19 from below, the name *superba* is to be inserted for **D. lulesa** *Schs.* According to a water-colour sketch very kindly sent by Mr. PAUL KÖHLER, the identity of *superba* is doubtless, the figure of which in BURMEISTER'S atlas is scarcely recognizable. The species is a typical *Dirphia*; *lulesa* becomes synonymous.

13. Family: *Uraniidae*.

Regarding this chapter we refer the readers to what has been said about the *Uraniidae* in Vol. II, p. 275; Vol. X, p. 93, and Vol. XIV, p. 387. Of the different American groups which contrast strictly with each other the *Uraniidae* are represented by the typical genus *Urania* which almost exactly corresponds to the African *Chrysidia* and — though only in the stouter structure — to the Indo-Australian *Alcidis*. The nocturnal *Sematura* are distinctly separated from the diurnal *Urania*; and even to the extent that they have recently been taken out of the family of *Uraniidae*. There is no parallel case of these *Sematura* in Africa, whereas they are almost exactly represented by the *Nyctalemon* in the Indo-Australian region, so that WALKER was even induced to describe them as *Sematura*. In America another group is united with the latter, i. e. the *Coronidia*-group containing almost 30 known forms and probably several unknown forms, so that it represents the largest group of the whole family, if the more remote *Epiplemidae* are separated from it, as we have tried to do in Vol. X.

On several occasions we have treated upon the most peculiar geographical distribution of the family. The unmistakable affinity between the South-East African *Chrysidia* and the purely American *Urania* is too distinctly evinced by their exterior, habits and — as we know now — by their early stages to admit the explanation of their resemblance by the congruence of their conditions of life. Owing to their long-lasting persevering flights and the roving spirit of many *Urania* it is rendered very difficult to understand the oicological conditions of the group. It is particularly the statements about the range of the American genus *Urania* which are so contradictory that we can only come to the conclusion that some species immigrate temporarily and then disappear again. Vast tracts of the South-American continent are positively professed to lack the genus *Urania*, whereas such great numbers of them are reported from small islands situated near the coast that one cannot conceive why this excellent flier has not mastered this small stretch of water. A parallel case is met with in the closely allied lepidopteral genus *Chrysidia* in Africa, since two distinctly separated species of the genus live on the opposite coasts of South-East Africa and Madagascar, both species being apparently absent in the Europa-Island as well as the Comoro-Islands situated almost exactly midway between them. Whilst the Brazilian *Urania brasiliensis* is reported to be common in some islands, but not to reach the opposite continent, GUPPY states that the northern *Urania leilus* continually wanders from the Venezuelan continent to the I. of Trinidad situated quite near to it and that, whilst only single females deposit their eggs there, the main swarms leave the island again and return to the continent.

A very similar roving spirit is also shown by the other species of *Urania*, and this peculiarity is also often mentioned in literature regarding *U. fulgens* and the West-Indian *U. sloanus*. Members of the family are even reported to swarm together before their departure as swallows or other birds of passage are in the habit of doing. They gather together within few days and, in flying off, they sometimes form real swarms. But this is by no means the case every year; on the contrary, only single specimens are often met with during a whole decade — the same is reported by Dr. REUSS of the African *Chrysidia* —, or the species seems to be entirely missing, until all of a sudden their number increases from one hour to the other and the lepidoptera dash about in crowds, sometimes even flying from the coast out to sea.

The places where the swarms gather are generally strictly localized areas to which the lepidoptera crowd together from all the surrounding districts. They frequently rest on the leaves of hanging wigs, keeping their wings flatly spread out, the forewings somewhat lowered, so that they partly cover the hindwings. The insects settle upright, but then quickly turn round until they sit with their heads down; the same behaviour is also stated by R. MELL of the Indian *Nyctalemon*. The imagines are often seen playing together, forming bands of 6 and more specimens, but apparently they do not fight with each other, as the butterflies frequently

do; this fact is confirmed by the peaceful way they flutter side by side on their migration, as well as by the excellent preservation of their most delicate wings, which has been ascertained on the captured specimens.

To capture these lepidoptera is not easy at all. They generally fly rather high, as long as they are near trees; it is therefore necessary to wait in open spaces in the forest or in prairies, where they fly lower down and may come within reach of the net (PUPPY), though even then their zigzag flight makes it rather difficult to capture them. Single troupes sometimes gather at places where water is running through rocky gorges and moistens the stone-walls, from which the insects greedily drink water, with their heads downwards and their wings spread out, too.

The behaviour of the *Sematurinae* is quite different from that of the *Urania*. They appear to be more nocturnal; the *Sematura* often come to the light, whereas the *Coronidia* and *Homodiana* are rarely seen near the lantern. Nor are they frequently beaten out from bushes or down from treetrunks in the daytime, but they often appear just for a few moments on the tops of mountains, whereupon they generally disappear again very quickly.

As the imagines of the *Urania*, the larvae also exhibit distinct relations with the *Chrysiridia* and the *Alcidis*. The young larvae, as far as they are known, have black and white transverse stripes with red head and pectoral legs, the prolegs and claspers of *U. leilus* being whitish, the cervical shield spotted reddish. The most peculiar feature, however, is exhibited by clubbed hairs on the foremost and hindmost segments. The larva of *Coronidia* is studded with shorter fleshy thorns, so that (according to FASSL) it resembles the larva of a butterfly from the genus *Anaea*, but otherwise shows the exterior of Noctuid larvae. The larvae of *Coron. achenais* were found on a low shrub with lanceolate leaves, partly hidden on trunks or in the moss.

The pupae are rounded in front, the head is slightly set off and the cremaster pointed; those of *Urania leilus* are light greyish fawn, with blackish spots and veins, those of *Coronidia achenais* are said to be similar to those of *Ennomos alniaria*.

1. Genus: **Urania** (*Uranidia* Ww., *Cydimon* Dalm., *Thaliura* Dunc., *Dasycephalus* Swns.)

The genus is composed of 8 rather similar species all of which exhibit greenish golden sparkling metallic transverse stripes through both wings crossing the deep velvety black ground. They are distributed over the whole northern part of South America, whilst they disappear in the south, so that they apparently do not pass beyond the frontiers of Chile and Argentina. In the north they do not reach the United States, but cross a great part of Mexico and even show their most beautiful forms in the West Indies (Cuba, Jamaica). They are remarkable for the great individual variation of the number and course of the green transverse bands which are sometimes even unsymmetrically arranged to the right and left. — The forewings are mostly regularly triangular, with a pointed apex, straight inner-margin and, in the ♂, a very slightly concave distal margin. As in *Chrysiridia*, 3 subcostal branches arise from the upper wall of the very short cell which does not even attain $\frac{1}{3}$ of the length of the wing, but is broad behind. The costal system, however, differs from that of *Chrysiridia* in the 2nd and 3rd subcostal branches not anastomosing here, as they do in *Chrysiridia* where they form an enormously elongated (nearly 2 cm long) areola. The hindwing is extended on the 1st median branch into a long tail, with long fringe and an open discal cell. Type: *leilus* L.

leilus. **U. leilus** L. (= *leilaria* Hbn., *surinamensis* Swns.) (138 a). The forewing shows 4 separated green lines, a fifth being fused with the base and 1 or 2 with the upper end of the main band. On the hindwing 2 feeble bluish-green stripes are parallel to the inner margin. The distal margin is broad green in extreme specimens, with a blue gloss at the apex, but mostly indented black from the direction of the margin in a variable intensity. The anal end, the tail, and the whole fringes are white. — The distal margin of the hindwing beneath is narrowly white also in normal specimens. The name: **amphiclus** Bsd. (138 a) refers to transitory specimens in which the distal margin of the hindwing is crossed by black stripes, the vein running through the tail is more or less broad black. 70 mm. Central America to Peru, Brazil. — The larva is extremely variable. All the young larvae are light bone-coloured, striped zebra-like by dark transverse bands, but the old larva may turn so dark violettish-brown that the black transverse stripes are scarcely noticeable. Moreover, the ground-colour may also be a light or pinkish yellowish-brown; the transverse belts may be merely fine lines or also broken up into transverse rows of dots. Besides very large white, black-edged stigmatal spots may occur. But invariably the adult larva shows a red-brown head and a dark-spotted face. The clubs of the hairs on the pectoral and anal segments exhibit white tips. The larva lives on species of *Onophalea*, a creeper; it feeds for about 3 weeks and then changes into a yellowish or greyish brown pupa with an irregularly dotted and spotted dorsum and strongly black-veined wing-cases. It lies in a widely meshed thin web surrounding it like a fine tulle. After about 16 days the imago appears, developing at night. It flies briskly in the daytime, playing around the twigs of trees, and likes to come to stones sprinkled with water. It always settles on hanging leaves and on rocks

where it immediately turns so that the head is downwards. The flight is rapid, restless and zigzag-like, generally also rather high so that in spite of the myriads of lepidoptera astounding sometimes the tourists it is not easy to collect a large number of not damaged specimens in a short time. — The egg has the shape of a cake with strong, projecting radial veins. — *curvata* Pfeiffer (138 a) is characterized as a form of *leilus* by the purely *curvata*. white fringe of the hindwing. The marginal spots are very feebly developed on the hindwing, but at the anal angle and tail there are yet so many white places that the form is nearer to *leilus* than to *brasiliensis*. It is chiefly distinguished by the green lines on the forewing, which are curved in such a way that they run vertically both to the costal margin and inner margin. Bolivia. — *brasiliensis* Swms. (138 a) does not differ *brasiliensis*. from *leilus* on the forewing. Only the fringes of the hindwings are throughout white, the green marginal spots are well separated, the anal end and tail quite black, eventually with green scales. Under surface also without white places. Brazil. — *intermedia* Pfeiffer seems to be identical with it, since the description mentions *leilus* and *fulgens* but not *brasiliensis*.

U. fulgens Bsd. (= *cacica* Gn.) (138 b). Mostly smaller than *leilus*. The green bands are turning yellow *fulgens*. or even reddish. In the apical area of the forewing there are mostly only few green scales which rarely form a short narrow band. On the hindwings the fringes at the tips of the dents and at the tail are always black; only at the end of the tail white and sometimes even the tail itself. On the hindwing beneath the spots only form numerous bands at the base, whilst they are rectangularly or squarely isolated at the margin. 55–65 mm. Mexico, Central America, Colombia. — *poeyi* H.-Schäff. (138 b), from Cuba, seems to be a somewhat larger *poeyi*. race of it (70 mm). The only specimen before me shows a short green band in the apical area of the forewing.

U. sloanus Cr. (= *occidentalis* Sws.; *sloanaria* Hbn., *sloaneus* Hbst.) (138 b). This species is likewise *sloanus*. inclined to develop yellow and red tints in the stripes of the forewing. A mostly very strong band is in the apical area, and another one mostly behind it, rarely before it. The spots on the hindwing are broadly confluent towards the centre and almost invariably golden red, so that a slight resemblance to the African species of *Chrysiridia* (Vol. XIV, p. 388) is produced. Forewing beneath with a broad blue inner margin, the bluish-green colour predominates also on the hindwing over the black spots and veins. 55–70 mm. — The larva of *sloanus* is black with a blue median line on the dorsum, this line being interruptedly margined with a broad white colour and followed by irregular white transverse lines, a thin one of which extends to the stigmata. Each segment bears one (or more?) long pencil of hairs which easily come off. The larva is said to drop for a short time on a long thread from its tree down to the water. It lives on *Omphalea triandra*, like that of *boisduvalii*. The pupa has no prolonged proboscis-case as that of *Cor. orithea*.

U. boisduvalii Guér. (= *fernandinae* Mac Leay) (138 b). The main band of the forewing extending *boisduvalii*. from the anal angle upwards is only slightly stronger than the others which are broader than in the other species. The bluish-green band of the hindwing from the centre of the costal margin towards the anal angle is broad and conspicuous, whereas the other species only show hardly visible rows of scales there (except *sloanus*). From the margin obliquely proximad narrow short streaks. 60–72 mm. Cuba.

2. Genus: **Sematura** Dalm.

It has been mentioned already in the introduction, that this and the following genera differ considerably from *Urania*, for which reason they have also recently been separated as *Sematuridae*. Only in order to save space, as in similar former cases, we renounce this surely justified severance.

Antennae almost $\frac{2}{3}$ the length of the forewing, slightly spindle-shaped at the ends in the ♂ and ♀. Second joint of palpus extending to the upper edge of the eyes, long-haired, the third joint thin, porrect. Vein 5 of forewing above the centre of the cross-vein, 6 on a short stalk with 10 + 7 + 8 + 9, vein 9 being merely a short spur. Vein 2 of hindwing stalked with 3 and 4, the cross-vein and vein 5 feeble 7 before the upper cell-angle, 8 behind the base sharply flawed to the cell. Without a frenulum.

Type: *lunus* L.

All the 5 species exhibit a dark brown ground-colour in the ♀ and a yellowish-white exterior band and similar lines on all the wings. The 4 first species are besides very much alike. The ground-colour of the ♂ is deep dark reddish-brown with ochreous lines and bands. At the cross-vein a dark reniform macula. At the base of the tail on the hindwing a black ocellus centred with blue, a smaller one in the centre of the tail on the inner side, a larger one before the end on the anterior side. The differences of the species are provided by the exterior band. In

S. lunus L. (= *actaeon* Fldr., *caudilunaria* Hbn.) (138 c) the 2 interior main lines of the exterior band *lunus*. are scarcely stronger than the others and both are equally strong, slightly distally convex between the veins, the interior one in both wings extends in long points proximad on the veins. On the outside of them there

are mostly 3 somewhat feeble, slightly undulated lines on the forewing and mostly 4 hardly undulated lines on the hindwing. In the ♀ above, especially on the forewing, the exterior main line is as broadly whitish as its distance from the interior main line, both lines straight, the interior one with inward notches as in the ♂. Sometimes also both lines form one uniformly whitish band. Forewing beneath paler brown, the entirely white exterior band straight or outside somewhat irregular. 75—85 mm. Mexico, Central America, Trinidad, British Guiana, Brazil. — According to PFEIFFER, *lunus* is separable from the following species or form *empedocles* by the following marks: *lunus* is said to be more thinly scaled, which I cannot notice, and has more pointed wings, the ground-colour is never so dark as it is sometimes in *empedocles*. The anal angle of the hindwing and often the whole margin is much redder in *lunus* than in *empedocles*. This intensely red colour, however, is not to be noticed in the bad original figure of CRAMER, and PFEIFFER is also inclined to consider them as one species, since there are also doubtful specimens among greater numbers of them.

empedocles.

S. *empedocles* Cr. (= *empedoclaria* Hbn.) regarded yet as a species by HAMPSON occurs in the same district as *lunus* and besides in Venezuela and Colombia. The exterior line of the exterior band on the hindwing has sometimes also inward notches. This mark will be just as uncertain as the degree of the red colour. —

selene.

S. *selene* Gn. (139 a) is placed to *empedocles* by HAMPSON. The original description is imperfect. It may be that the specimens described below belong to this form here: the exterior line of the two main lines is distinctly stronger than the interior one, but not so strong as in *diana*. The other lines are as notched as in *lunus*. Instead of the fine lines on the veins within the main lines there are more pointed angles here. The red colour on the hindwing varies as in *lunus* and *empedocles*. The ♀♀ vary in the width of the white band, resp. the intensity of the double lines and the red colour on the hindwing to such a degree that one can hardly tell to which of the 3 forms a certain specimen is to be assigned. It would be best at any rate to cancel the name *selene* owing to its insufficient description. According to DRUCE, *selene* is the same as *lunus*.

diana.

S. *diana* Guen. (138 c) shows the exterior line of the exterior band in both wings much stronger than the interior one, and almost straight; only on the hindwing it becomes irregular near the end. In the ♀ above half or more of the exterior band is whitish-yellow, narrowly edged with dark inside, and much broader than in *lunus*. Beneath it contrasts much more intensely with the darker surroundings than in *lunus*; in the middle it shows sometimes a few dark scales and may be accompanied outside by a light line. The submarginal line is strongly undulated in the ♂ and ♀ and exhibits a light spot between veins 3 and 4. The margin behind it is mostly somewhat lighter. This spot is a good mark of distinction of the species in both sexes. 70—90 mm. Brazil.

aegistus.

S. *aegistus* F. (= *excavatus* Wkr., *lunigera* Hbn., *lunus* Cr., *phoebe* Gn.) (138 c) corresponds with the others in the colour, but it is easily discernible by the exterior line (not band) in the ♂ forming an angle in the forewing above vein 5 and then extending incurved, notched, obliquely outwards to the submedian fold. It is quite irregularly notched on the hindwing. It is inside edged with dark in both wings of the ♂, whilst in the ♀ there is a light band with less sharp notches instead of it. 70—80 mm. Jamaica, Haiti, Surinam. — According to PFEIFFER, *selene* is the same species, and WESTWOOD already considered this to be possible, too.

3. Genus: **Coronidia** Ww.

Palpi and neurulation of both wings almost the same as in *Sematura*. The hindwings only show short broad little tails. Antennae of the ♂ at the ends somewhat more fusiformly thickened than in *Sematura*, those of the ♀♀ bipectinated. This case is unparalleled. The forewing beneath of the ♂ exhibits a hair-pencil above the inner margin. Hindwing always with a blue band which is broader in the ♂. Type: *orithea* Cr.

hyphasis.

C. *hyphasis* Hpff. (139 b) is discernible from the other species by the position of the white cross-band on the forewing being well separated from the light narrow distal margin. It bears a fine white triangle inside in its centre in the ♂. The blue band on the hindwing exhibits a white spot at the costal margin in the ♂ and ♀. 42—52 mm. Mexico, Costa Rica, Panama, Ecuador.

The transverse band of the forewing ends at about the anal angle in all the following species.

erecthea.

C. *erecthea* Ww. (= *hysudrus* Hpff. pro parte) (139 b). On the forewing the transverse band is slightly dusted with rusty red, notched inside and narrower in the ♂, broader and rectilinear in the ♀. The submarginal line is very little incurved at the apex. The blue band of the hindwing is slightly reddened at its end in the ♂ and ♀. 50—55 mm. Mexico, Brazil.

difficilis.

C. *difficilis* Strd. (139 b) is very similar to the following species. The ♂ is recognizable on the forewing by the absence of the light undulate line at the margin. The transverse band is narrower and less notched, slightly inserted. The blue band of the hindwing is less broad. The forewing of the ♀ shows a purer white, somewhat narrower transverse band, whilst the band on the hindwing of the ♂♂ and ♀♀ is more light blue, without the violet gloss of *orythea*, and less red at the end. On the forewing beneath the transverse band is of

ecuadorensis.

sis.

a bluish gloss in the ♀, and the hair-pencil of the ♂ is black. 50—55 mm. Chanchamayo. — **ecuadorensis** Strd. shows a very narrow transverse band of the forewing, and besides it is brownish in its interior half. The blue

band of the hindwing is narrower. The hair-pencil beneath seems to be broader and as yellow in its basal half as in *orythea*. Ecuador.

C. orythea Cr. (= d'Urville Latr., hysudrus Hpff. pro parte). The species is already characterized by *orythea*. the differences stated in *difficilis*. The ♀ may exceptionally also have a notch inside at the transverse band, and the blue band on the hindwing may be somewhat broader. The transverse band beneath is white. — **boreada** Ww. differs somewhat in the brown basal band at the inner margin being prolonged to the place where *boreada*. it meets the main band. 46—56 mm. Mexico to Brazil, Paraguay.

4. Genus: **Homidiana** Strd.

Not different from *Coronidia* in the neuration. The ♂ lacks the scent-pencil on the forewing. Antennae of ♀ like those of ♂. Third palpal joint sometimes longer in the ♀ than in the ♂. Wings shaped as in *Coronidia*.

1. Species with a red band on the hindwing.

H. tangens Strd. (139 c). Both bands on the forewing edged outside with a somewhat lighter colour. *tangens*. The carmine spot on the hindwing extends broadly to the costal margin. Forewing dark also beneath, cross-band brownish-grey, edged with deep black inside, with reddish-white outside. Submarginal line likewise reddish-white. The red band on the hindwing beneath is darker, its interior edge straighter than in *westwoodi*. ♂ 55 mm. Ecuador.

H. westwoodi Oberth. (139 c). ♂. The two bands on the forewing are somewhat narrower than in *tangens*. *westwoodi*. The spot on the hindwing is only pinkish-red but similarly broad. The transverse band on the lighter brown forewing beneath is almost white, little bent, edged with a somewhat darker colour. The pink band on the hindwing is somewhat narrower and longer towards the inner margin than above. A pink line also behind it in the marginal area. ♂ 52 mm. Colombia.

H. traducta Strd. (139 c). ♀. The interior line on the forewing extends somewhat more obliquely than *traducta*. in *westwoodi*, the main band is broad, straight, slightly brownish. The red band on the hindwing is darker, similarly shaped as in *westwoodi* beneath, with a red line before the margin instead of the brown one of *westwoodi*. Forewing beneath with a broad white transverse band, the submarginal line also broader than in *westwoodi*. The hindwing almost entirely lacks the fine red lines in the marginal area. As HAMPSON describes the ♂ as follows: "Main band of forewing less dentate inside than in the ♀; basal and interior lines not with bluish-white scales", he has evidently had no *traducta*-♀ before him, but perhaps the otherwise unknown *westwoodi*-♀. 55 mm. Bolivia.

H. leucosticta Hmps. ♂. As there are no characteristic differences from other species mentioned, it is *leucosticta*. difficult to say anything about the species. The red band on the hindwing is as short as in *tangens*, but with undulated edges. The white transverse band on the forewing beneath is excurved.

H. rosina Fldr. is a very conspicuous species. The exterior and interior bands on the forewing above *rosina*. are broad brownish-white, almost straight, darker in the ♂. The similarly coloured submarginal line extends to vein 4, being more remote from the margin than usual in both wings. The red band on the hindwing of the ♀ almost extends to the inner margin. Forewing beneath with a longer submarginal line; large pinkish-white submarginal spots on the hindwing are situated far off from the margin. 55—60 mm. Colombia, Venezuela.

H. egina Blanch. (= nicaraguana Ww.). The basal line on the forewing is not very light. The treble *egina*. interior band forms an angle below vein 2 in ♂ and ♀. The likewise treble exterior band is slightly excurved behind the cell, distally light-edged in the ♂, the edge of the ♀ somewhat broader, the undulated median lines more prominent. The red band on the hindwing of the ♂ narrower than in the ♀, somewhat angular at its end. The forewing beneath shows the white main band also slightly excurved; the space from a little before it to the light submarginal line is dark brown, but lighter behind the latter line. The pink band of the hindwing extends to the inner margin, the distal margin is also pink outside, blackish-brown before it with pink lines. 45—60 mm. Mexico, Central America, Colombia, Ecuador, Peru.

H. anilina Bryk (139 c). Both wings very similar to *egina*, but easily separable on the forewing by the *anilina*. exterior band being only composed of 3 equally strong lines which are very strongly notched. Thus it resembles *subpicta* which, however, belongs to another group for the yellow band on the hindwing. ♂ 50 mm. Bueyes (Bolivia).

H. restincta Strd. (139 c). The treble interior line on the hindwing is similarly situated as in *egina*, *restincta*. the likewise treble exterior line is somewhat more excurved behind the cell in the ♂, with hardly any notches on the inside. Marginal area similar to that in *egina*. Forewing of ♂ only with a narrow greyish-white line instead of the usual band, and distally to it a few lighter undulated lines at the inner margin. Exterior line of ♀ intensely white outside and shaped as in *egina*. The very narrow pink band of the hindwing ends at vein 5. only the marginal lines form the usual angle there and extend further to the inner margin. 55—60 mm. Ecuador.

H. canace Hpff. (= *egina* Hpff., *cana* Hpff., *paulina*-♂ Ww., *aeolata*-♂ Ww.) (139 d). Very similar *canace*. to *egina*. Basal line of forewing as light as the innermost of the treble interior line which is straight or slightly

flawed below the cell. The exterior line is broadly edged with white outside and likewise varies somewhat in the intensity of the curve, being often quite straight in the ♀, but always behind it vein 5 distinctly white. The red band on the hindwing is more angled than in *egina*. Forewing beneath scarcely different from *egina*, the exterior band on the hindwing is mostly somewhat yellowish and undulately defined, the distal margin never pink. 50—62 mm. Panama, and northern half of South America. — In a form from the Chanchamayo and Chiriqui the light line at vein 5 of the forewing is less prominent, the reniform macula is rather conspicuous. The band on the hindwing is rather orange and perhaps somewhat less angled. Colour beneath pale yellow.

guenei. little dusted with dark at the apex. It may be the form mentioned by DRUCE: — *guenei* Drc.

ledereri. **H. ledereri** Pfeiffer. Similar to *canace*. The interior band on the forewing is somewhat excurved, the exterior band forming a long inward bow so that the distance of the two bands, at the narrowest place, is hardly as large as their width. As a specimen forming the transition to it, from the Chiriqui in the Berlin Museum, surely belongs to *canace*, it may be that *ledereri* is only an extreme aberration. Described from Ecuador.

strandi. **H. strandi** Pfeiffer also resembles *canace*. Very dark brown. Basal line of forewing moderately light, excurved at the inner margin. Interior line neither very light. Three light lines in the median area similarly notched as in *canace*, their bows towards the inner margin nearer to the exterior band which is bluish-white, parted by 2 fine brown lines, split in the middle at the costal margin; the band is sharply dentate inside. Two almost white submarginal lines. Hindwing with a short red band of 3 mm width, ending before the inner margin near the anal angle. Forewing beneath with a white main band and submarginal line, being pink on the hindwing, the distal margin paler. 50 mm. Peru?

2. Species with a yellow band on the hindwing.

subpicta. **H. subpicta** Wkr. (= *echenais* ♂ *Hpff.*, *biblina* ♀ *Ww.*, *grenadina* *Ww.*) (139 d). The ♂ with a broad median band being darker at the edges. Numerous light lines in the basal area, the reniform spot intense. The exterior edge of the median band with white inward notches, faded undulated lines behind it. Submarginal line sometimes with white spots. Hindwing with a bright yellow band, a yellow and white spot at the apex. The ♀ exhibits the median band of the forewing replaced by a sometimes double, feebly white interior line, besides a white exterior band which is slightly brownish before its interior edge. It extends almost rectilinearly to the anal angle and is slightly excurved behind the cell. 50—60 mm. Mexico to Peru, Bolivia. — The original figures of *subpicta* show the band on the hindwing more faded than in the type of *echenais*, but the difference will be due to the imperfect description.

monotona. **H. monotona** Hmps. ♂. Forewing red-brown, dusted with grey. The dark oblique lines in the basal area are distally edged with white at the costal margin. The cross-vein and exterior line are black; the latter indistinct, faded, excurved as far as vein 4, then strongly inwards. Marginal area somewhat greyer as far as below vein 4, below which an undulated black submarginal line extends to the submedian fold. Hindwing pale reddish-brown, the band orange, incurved from vein 5, ending at vein 2. Fringe white at the apex. ♂ 55 mm. Peru.

rubrivena. **H. rubrivena** Dogn. Forewing brown; dusted somewhat brownish ochreous, reddish and lilac, and traversed by undulated blackish-brown lines. Veins reddish, cross-vein black, edged with lilac in front. Some incomplete lines in the basal area. Interior line double, strongly excurved at the inner margin, then some ochreous spots at the costal margin. Exterior line double as far as vein 4, then single, obliquely outwards as far as before the anal angle. Somewhat lighter at the margin. Hindwing brown, in the middle third of veins 1—5 ochreous, with lilac scales between veins 1 and 2. Marginal line yellow, enclosing some black ocelli as in *evenus*, the tail likewise very short. ♂ 52 mm. Colombia.

3. The ♂ of the following species has no yellow band on the hindwing.

The forewing partly also without a light exterior band. ♂ and ♀ of a very different exterior.

brachyura. **H. brachyura** Hmps. Both wings deep dark reddish brown, forewing with black lines. Interior line indistinct, double, undulated, oblique. Median line edged with somewhat grey, oblique as far as the median vein, then undulated. Exterior line finely edged with grey outside, oblique at the costal margin, then undulated and vertical to the inner margin. Submarginal line undulated, double, indistinct with black oblique streaks before the margin. Hindwing with white fringe at the apex, an undulated black line below it as far as the tail which is without a white spot as in *evenus*. ♂ 40 mm. Ecuador.

evenus. **H. evenus** Blanch. (= *ducalis* *Schauf.*, *ducatrux* *Schauf.*) (139 a). On the ♂ forewing the dark median area is said not to contrast so much with the lighter basal and distal areas as in *briseis*, but nevertheless the dark shadow before the submarginal line is said to be distinct. Hindwing with many finely notched light submarginal lines, being distinct at the inner margin. The figure is that of *subevenus* *Strd.* which is presumably the same as *evenus*. The ♀ is similar to *leachi*. Forewing red-brown and grey, but the interior band whitish-brown. The whitish exterior band is brownish in its interior portion, except at the costal margin, where it is somewhat obliquely inward, otherwise vertical, somewhat notched. The orange band on the greyish-brown hindwing is sometimes a little broader than in *briseis* and extends to vein 2. 44 mm. Colombia, Venezuela, Ecuador, Bolivia, Peru.

H. hoppi Bryk (139 d). Forewing similar to *evenus*-♀ by the notched interior edge of the light exterior *hoppi* band; the dark undulate lines behind it likewise recall *evenus*. The hindwing resembles more *leachi* by the narrow yellow band. This band is narrow and bright yellow beneath in *hoppi*, somewhat broader and strewn with red scales in *leachi*. ♀ 48 mm. Pasto (Colombia).

H. briseis Ww. (= *leucothysanota*-♂ Strd.). The ♀ forewing is reddish-brown at the base, the interior *briseis* band somewhat lighter, pointed at the inner margin. Its exterior edge is uniformly convex, or undulated, reetilinear. Median area very dark red-brown, excurved behind the cell, then slightly outward and straight to the inner margin, or forming an angle in the submedian fold, above which it is inserted. The light red-brown exterior band is only bordered outside at the costal margin, otherwise broadly flown out. Light oblique spots before the distal margin. Hindwing with the orange band widened at vein 5, but sometimes much less so, whilst it is normally broad beneath. Fringe white at the apex and the tip of the tail. ♀ 45—50 mm. Venezuela, Bolivia, Peru. I cannot tell whether HAMPSON is correct in regarding *leucothysanota* Strd. as the ♂ of it; it may also be a uniformly darkened specimen of *subevenus* Strd. The only difference in the scheme of markings is on the forewing: a somewhat feebler angle of the median band outside, at vein 5. The few ♀♀ before me likewise differ a little from each other, so that *evenus* and *briseis* may be the same species.

H. leachi Latr. (= *japet* Blanch.) (139 a, d). The ♂ is above the same as *subevenus*, but separated on *leachi* the hindwing by a white apical spot, not only white fringe, and a somewhat larger tail. Yet ♂♂ occur also with a more or less continuous exterior band as in the ♀, but the band is then brownish-white. It is always white beneath. The ground-colour of the ♀ is somewhat lighter than that of the ♂. Interior band of hindwing uniform, not so notched as the corresponding lines of the ♂, narrower towards the inner margin. Exterior band also less notched, slightly bent at vein 5, filled with light brown inside, with yellowish-brown outside, sometimes also brownish-white as in the ♂. The light distal portion of the marginal area is more distinct than in the ♂ and entirely defined. Hindwing with a uniformly narrow orange band with somewhat notched edges. 50 mm. From Mexico to Brazil, Peru, Ecuador.

H. aenophlebia Hmps. Forewing deep red-brown, dusted with grey, the veins pale red-brown, similar *aenophlebia* to *rubrivena*. Interior line treble, undulated, bent. Cross-vein black. Three indistinct undulate lines behind the cell. Exterior band narrow, reddish-yellow, parted by a dark line, and edged with black; a grey and black line before it; the costal margin behind it reddish-yellow with small black spots. Then follow 2 black undulated marginal lines. Hindwing very dark, especially at the margin, where there is an undulated black line, edged with white inside, between veins 2 and 7. Fringe white at the apex and above the tail. ♂ 50—54 mm. Ecuador, Peru.

5. Genus: **Lonchotura** Hmps.

Antennae of ♂ and ♀ fusiform. Neuration as in *Coronidia*, but the wings somewhat differently shaped. But as the shape of the wings is neither constant in the following genus and all the 3 pairs of tibiae are spined in both the genera in contrast with *Coronidia*, the name *Lonchotura* is really superfluous.

L. ocyllus Bsd. (= *genevana*-♂ Ww., *dutreuxii* Deyr.) (138 d). Forewing in one specimen distally *ocyllus* angled at vein 6, otherwise straight. Olive brown, median band darker, its interior edge widely excurved in the middle, its exterior edge feebly excurved at vein 5, then almost vertical. The wing is lightest behind this band. The white submarginal line is distally angled at vein 6, broadly dark before it. The greyish-brown hindwing shows a short orange band with an indistinct prolongation to the inner margin. — **peruviana** M. Her. (138 d) *peruviana*. is as dark in the basal area as in the median area, so that their border is rather indistinct, though the border-line seems to be less excurved. The distal border of the median area and the submarginal line are light and distinct on the uniformly dark ground. The hindwing is without the brightening in the tail of *ocyllus*, but an eye-dot is present. ♂ 42—46 mm. Central America to Ecuador, Peru.

L. fassli Pfeiff. has been described as a *Homidiana*, but the shape of the wings makes me think that it is *fassli* allied with *ocyllus*, though the dark colour of the ♂ is more like that of *leachi* and *evenus*. Forewing of ♂ with many dark reddish-brown undulate lines. Interior line 1½ mm broad, indistinctly dark brown, exterior line slightly S-shaped, just as broad, outside reddish-yellow, inside darker and dentate, parted in the middle, ending near the interior angle. Distal margin 2 mm broad reddish-brown, enclosing a black undulate line which is edged with light inside. Hindwing greyish-brown, with black and brown undulate lines in the inner-marginal third. The ♀ shows the same ground-colour on the forewing. The shape of the two bands is almost the same as in *leachi*. Interior band indistinct, parted by a dark line; exterior line outside somewhat undulated, brownish-yellow, inside sharply dentate, fine dark. Margin light brown, posteriorly broader, extending to the exterior band. Hindwing greyish-brown, the brownish-yellow band 2 mm broad, only present in the posterior portion. ♂ 42 mm, ♀ 37 mm. Rio Aguaca, Western Colombia. I doubt whether the two sexes really belong to one and the same species.

6. Genus: **Anurapteryx** *Hmps.*

Separated from *Lonchotura* by the shape of the wings. The margin on the hindwing is slightly undulated in the typical species. Type: *beckeri* Drc.

beckeri. **A. beckeri** Drc. (138 d). Forewing reddish-brown with a darker median band. Its edges are undulated; the interior one extends from the costal margin obliquely outwards to the base of vein 3, then vertically to the inner margin; the exterior one below vein 6 obliquely distad, then vertically on. The brightening behind the median band at the costal margin is feebler than it is figured by DRUCE. The dark submarginal line is indistinct, the black undulated marginal line distinct. Hindwing orange; blackish-brown at the inner margin as far as the cell and the indistinct median line. The margin is narrow and indistinctly dark. 40—45 mm. Mexico, Guatemala.

gephyra. **A. gephyra** M. Her. (138 d). Forewing as in *beckeri*, but the light spot at the costal margin whiter. Submarginal and marginal lines as well as the space between them lighter. The whole basal area of the hindwing is dark, notchedly defined. A narrow notched yellow band behind it is somewhat angular in the middle. Beneath rather much like *beckeri*. ♀ 48 mm. Guatemala.

brueckneri. **A. brueckneri** M. Her. (138 d) is somewhat smaller. On the forewing similar to a darkened *beckeri*. Hindwing smoky brown at the inner margin as far as vein 3 upwards and from the costal margin to vein 7, also at the distal margin; the remaining median area orange. A narrow somewhat lighter band beneath is less distinct on the forewing. ♂ 36 mm. Guatemala.

interlineata. **A. interlineata** Wkr. (= abbreviata *Maass.*, *liriope* *Weym. i. l.*). In spite of its size and the tail on the hindwing the species belongs to this place owing to the spined tibiae as Dr. M. HERING has proved. The under surface is also very similar to *beckeri* and differs a little in the arrangement from that being usual in *Homidiana*, so that one can probably decide accordingly, even in specimens without legs, whether it is a species of *Anurapteryx* or not. The broad dark median band of the ♂ is very concave between 4 and 2 and parted by a light patch at the costal margin. The yellow band on the hindwing is broad, often split at the end. The interior line on the ♀ forewing is somewhat lighter than in the ♂. The double exterior line is shaped as the distal edge of the median band in the ♂, the interior branch stronger, lighter. The yellow marginal line on the hindwing is often anteriorly longer than in the ♂. 44—54 mm. Central America to Ecuador, Peru. — **meticulosa**-♀ *Pfeiff.* The light streak at the cross-vein on the forewing does not only despatch indistinct notched lines, but it is continued almost to the interior line on the centre of the wing incurved to the middle of the inner margin. The light interior and dark exterior portion of the exterior band is not separated by a blackish line. The yellow interior band on the hindwing beneath is also marked above. Rio Aguaca, Western Colombia.

flavidorsata. **A. flavidorsata** *Hmps.* Thorax olive, tegulae and patagia with dark brown edges. Abdomen reddish-yellow with a dark median line. The ground-colour of the ♂ is olive and reddish-brown in the median and distal areas. The basal and interior lines probably similar to *interlineata*-♀, with angles at veins 2 and 1. The light patch at the costal margin of *interlineata* is represented here by a white median line with an olive band behind it, extending along the median vein to the interior line; then obliquely outwards with a small angle at vein 1; enclosing a blackish-brown triangle at the costal margin as far as the median vein. The olive band is distally edged by a black double line which is angled inwards at vein 1. Exterior band as in the ♀ of *interlineata*, purely white inside, with inward points at veins 4—1. Submarginal line also white, undulated as far as vein 5, then as in *interlineata*, also with black oblique streaks. Hindwing greyish-brown with an orange-red band as in *interlineata*, but ending at the inner margin with 2 white streaks. Before this band another faded reddish-yellow band from behind the upper cell-angle to vein 4 near the main band and terminating at vein 2. This additional band is less distinct in the ♀, oblique, extending from 6 to 4. 50 mm. Colombia, Peru.

insolita. **A. insolita** *Strd.* (138 d) is very similar to *interlineata* by the shape of the spotted median band on the forewing. A fine light line at the margin at vein 7. Hindwing light yellow, blackish at the inner margin as far as vein 4 with an interruption in the middle. Hindwing beneath with more numerous finely dentate lines than in *interlineata*, otherwise very similar to it, although the upperside of the hindwing is rather different. ♂ 42 mm. Exact patria not stated.

ribbei. **A. ribbei** Drc. (138 d). Forewing cut out at the distal margin below the apex, in the ♂ also similar to *interlineata*, but less distinct. An exterior band is marked by a lighter colour. A narrow notched yellow band on the hindwing extends to the inner margin. A reddish-brown exterior band in the ♀ is as feebly curved as in the species of *Homidiana*. In the median band the rhombic spot at the costal margin and the narrow one at the inner margin are more prominent than in the ♂, as is also the case in *interlineata*-♀. Very dark before the strongly notched submarginal line. Hindwing beneath quite similar to *insolita* and *interlineata*. 38—42 mm. Panama.

crenulata. **A. crenulata** *Barn.* Forewing above pinkish reddish-yellow, the broad median band intensely dusted with grey, strangulated in the middle; notched outside, indistinctly edged inside. The basal area is paler, likewise dusted with grey. Lightest behind the median band and gradually turning blackish-brown towards the submarginal line which is composed of pale lunae edged with dark grey. Marginal area pale. The whole wing with dark fine notched lines. Hindwing grey at the base, defined by an irregular dark line, behind it somewhat more pink than on the forewing. ? mm. Arizona. — Judging from the patria, the species is presumably not correctly ranged here.

14. Family: *Sphingidae*.

It was K. JORDAN who in Vol. II (p. 229) already pointed out the homogeneity of the exterior of all the moths belonging to this family. He described all the three stages of the *Sphingidae* in such a correct and precise way that we merely need to refer to that passage. In fact, already the earliest authors working with the most imperfect means of help have made very few mistakes in classifying the lepidoptera from this family; they especially included by mistake certain *Notodontidae* in the *Sphingidae*, mostly because they had defective or deformed specimens before them. Owing to this homogeneity it is rather easy to decide whether an insect belongs to this family or not, but on the other hand it is difficult to define the single genera and groups of genera; this task, however, has been most classically solved, in spite of this difficulty, in the excellent monography of ROTHSCILD and JORDAN, which we have already referred to in Vol. X (p. 524).

As nearly all the *Sphingidae* are most conspicuous insects, mostly also of very large or medium sizes, they have always created special interest also among the laymen. Specimens captured partly on flowers partly on the lantern were particularly often brought from abroad to European Museums and private collections, so that our knowledge of the more conspicuous forms has made more rapid progress than that of those families containing more insignificant lepidopteral forms or composed entirely of such forms. The first catalogue by KIRBY, which was fairly complete considering the time of its origin in 1892, comprised the names of 912 species; ten years later, ROTHSCILD and JORDAN enumerated 770 species, whilst the latest list (in JUNK's *Lepidopterorum Catalogus*) drafted by H. WAGNER in the years 1913—1919 records 849 species. The strange fact that the number of species has not increased but decreased within 30 or 40 years is not due to the reason that formerly described species have been lost or omitted, but that forms which were formerly regarded as species have meanwhile been recognized to be modifications of other species, or geographical representatives, local forms, condition forms, or slight deviations not worth being denominated.

It has already been stated in Vol. XIV (p. 353) that the resemblance of the shape is to be considered as the consequence of the adaptation to a highly developed air-life. The body has almost exactly the shape of a fish or gull, or of a humming-bird the flying power of which is scarcely to be excelled. It is the same, almost cigar-like shape of the body, which has been applied in aviation in the shape of the Zeppelins and in the bodies of aeroplanes, and which has thus also been acknowledged in technics to be the most serviceable for aviation.

This eminent flying power has also led to an extensive geographical distribution (cf. Vol. X) so that we meet with *Sphingidae* not only in all the continents but sometimes even in quite remote islands, as for instance *Herse convolvuli* in New Zealand, all of which we immediately recognise to have immigrated across wide oceans.

The general distribution of the Sphingid family over the whole globe is chiefly adjusted to the climatic conditions; the number of both their individuals and species decreases quickly towards the polar regions, being largest in the watery forests of tropical and subtropical countries and sometimes decreases to nought in deserts lacking every vegetation. This is the case in all the continents; the same in America as in the warm countries of the Old World. Moreover, the family also lacks all the real cold forms, i. e. we do not know of any species which, on its wanderings from warm zones to colder districts, would appreciably change its exterior: it is merely sterility that ensues, which is recently presumed to be chiefly an effect of the cold, preventing at the same time their settlement at the eccentric destination of their wanderings.

As the American Continent in Mexico is divided by a desert into a northern and a southern section, the fauna of the southern nearctic region is also separated from that of the northern neotropical region. Of

about 250 Sphingid species known from America only 20 have succeeded in traversing this desert. We have stated at another place that because of their great want of food the *Sphingidae* being otherwise provided with such an excellent flying power are unable to fly across districts void of vegetation; they will not grow exhausted in such an attempt, but they will die of starvation. There is hardly any group of lepidoptera the imagines of which exhibit such a greed after food, and hence their communication between North and South America is most strongly obstructed. The fact that the entire American Sphingid fauna contains but 2 species occurring also in the Old World is due to another cause. In Vol. X we had stated that the *Sphingidae* chiefly belong to the more modern periods of creation, and that is evidently also the reason why the modern climatic conditions have been decisive for them. Their emigration from America to Western Europe, or from Eastern Siberia to Alaska might have taken place in such northern latitudes in which the arctic cold being unbearable for *Sphingidae* makes it impossible. Thus we do not find any single American Sphingid species in Eastern Asia, and only two species — these even rather widely distributed — in Europe and North America. Even very extraordinarily distributed lepidoptera, such as the *Acherontia* occurring from Lissabon to Japan and from the Cape of Good Hope to Central Europe have not been able to advance to America. The extremely problematic "Atlantis" — if it ever existed — certainly did not exist at the time when the *Sphingidae* spread over the world.

The genera common to both the New and Old World are naturally those which are able to advance farthest to the north: i. e. the genus *Smerinthus* the Canadian form of which, *S. cerisyi*, is a continuation of the European *S. ocellata* extending to Lapland, Scotland, and England, and *Sphecodina* which extends in Eastern Asia to Siberia and which, though it does not occur any more in the nearctic west of America, is frequently met with again in the east in the winter-cold lake district.

There are also other parallel features of these very homogeneous *Sphingidae* in the New and Old World. The exterior of the palaearctic *Acherontia* is opposed in America by the *Grammodia*. The American *Protambulyx* from the *eurycles*- and *strigilis*-group we find sitting in almost the same position on the large leaves of low shrubs in the open daylight as the Indian *Oxambulyx*. The palaearctic *Macroglossa* appear in America as *Sesia* and *Eupyrrhoglossum*, the South-Asiatic *Panacra* as *Perigonia*; all these convergencies cannot be wondered at considering such homogeneous habits, and they must not be used as a proof of systematic affinity.

The differences between the various American Sphingid groups can only comprehensively serve as a key for a natural grouping; there is no organ exhibiting such thorough differences as to be able to build up a system of the *Sphingidae* on it; this also proves that the genera and species belonging to this family have been separated at a relatively late period, which assumption is substantiated by the great easiness of the copula not only between different species, but even different genera. These trials have almost become a sport, since new and often wonderful combinations are produced nearly every year. Nor do these hybrids by any means make the impression of stunted forms or unnatural deformities, but on the contrary they represent insects fully capable of living, and even the hybrids from mixed copulae of different genera bring forth prolific individuals. Such hybrid larvae yielded by mixed copulae, as DENSO already stated in Vol. II (p. 260 sq.), even prove to be of a particularly excellent appearance and to grow up very quickly. C. F. FRINGS reports that hybrid larvae of *hybr. johni* Frings were already transformed to pupae after 16 days, thus in a space of time in which neither of the parental species (*Smerinthus planus* ♂ and *Amorpha populi* ♀) use to terminate their larval stage.

As most of the other lepidopteral families the American *Sphingidae* also exhibit a great abundance in gigantic forms. The species of the genus *Cocytius* with an expanse of almost 20 cm extend through the whole neotropical region and sometimes even advance to the United States. They represent, in a certain measure, our *Acherontia* which are absent in America and seem likewise to be subject to a continuous roving spirit, at least I frequently found the dead bodies of these lepidoptera on the Brazilian Coast, which had been deposited there by the tide. The *Pachylia* also develop very bulky bodies and their larvae may become so very heavy that the twigs of young food-bushes are bent down by their weight, and this is still more remarkable in the *Pholus anchemolus* living on creeping plants. Dwarfish sizes of certain palaearctic species, such as *Sphinge naepiopsis nanum* or *obscurus*, do not occur in America.

The colouring of the American *Sphingidae* does not differ typically from the palaearctic forms. The visible parts of the body are here likewise hidden by bark-like or leaf-like colouring or shades in most of the resting lepidoptera, the bright red or yellow colours are confined to the hindwings which are covered in the resting insect and the covered dorsum of the abdomen. The flying imago exhibiting the very bright colouring seems to be well protected by its swift flight and easily to notice an approaching enemy by the aid of its very large night-eyes and a certain shyness, even when sucking from blossoms, can be noticed as long as the dawn-time which is very short in the tropical districts allows our eyes to watch the insect.

The *Sphingidae* almost invariably live on flowers and very few of the American species take up any other stuff for their principal food. The proboscis which is mostly well developed except in some *Ambulicini*, attains a monstrous length in some species such as the *Cocytius* and seems to induce the insects to visit especially blossoms with deep calyces. As we have already stated in certain palaearctic species, the American species likewise exhibit a mutual adaptation between certain blossoms and *Sphinges*. Thus for instance *Mirabilis jalapa*, the marvellous Mexican flower, keeps its blossoms closed during the day and opens them towards evening at about the same time when the *Sphingidae*, especially also the species of *Celerio*, the larvae of which live on the *Jalapa*, begin to swarm; it even seems as if most of the night-flowers (*Nyctaginaceae*) specially preserve their honey for the *Sphingidae*, shutting themselves off from all the diurnal insects, such as bees, flower-beetles etc.

The proboscis of the *Sphingidae*, however, does not only serve for taking up honey but especially also for drinking water, because the *Sphinges* of the torrid zones of America are in particular need of it. From the banks of the camp-brooks and forest-rivulets one may see, towards the hours of dawn, all sorts of species of *Sphingidae* flying across the surface of the water which they sometimes touch. In spite of the very skilled flight of nearly all the *Sphingidae*, it frequently occurs in this process of sucking up water that some individuals sink too deep into the water and cannot rise any more, especially when being snatched at by an enemy.

It is not only the light of lamps but especially the sight of certain blossoms by which the *Sphingidae* seem to be allured from great distances. American entomologists state the *Verbenaceae* to be particularly favoured, which is also the case in the tropical Indian regions. Certainly the *Sphingidae* are less frequently found sucking during the day on the blossoms of *Lantana* — which is also widely distributed in Brazil — because there are no species of *Macroglossum* in South America, whereas dozens of specimens of 3 or 4 different species are often to be seen swarming on a little shrub of *Lantana* in South Asia. The American blossoms of *Lippia*, the orange-like smell of which — as for instance *L. citriodora* — can be detected at great distances, are of course also very much frequented; but also blossoms introduced from Europe, such as woodbine, a shrub of which crept up my verandah in the Itatiaya Mts., were sometimes visited by tropical *Sphingidae*.

The variability of the attractive effect of lamps on the Moths, especially on the *Sphingidae*, is most puzzling. In numerous places of the earth it has been observed that at the time of introduction of electric light the number of *Sphingidae* is enormous at those places which had formerly been without light, but that this effect decreases rather abruptly after some months or even weeks, and does not reoccur, except on single evenings that are extraordinarily favourable for flying. A. MILES-MOSS, from Pará, states that in the year 1895, when the first arc-lamps were lit, certain *Sphingidae* came flying to the lamps in immense numbers, whilst hardly ten years later they had become very rare. Moss presumes this to be due to the decimation in the surroundings of the lamps, brought about by the moths being diverted from their natural life-habits. This explanation given with a reservation by Moss is also insufficient in my opinion, for in such cases the larvae would also be found to have reduced in numbers, which I could not ascertain in searching for them on the bushes near the lamps. The diminution of numbers of *Sphingidae* flying to the lamps, which is almost uniformly shown by all the Moths, is too sudden to be in favour of such an explanation. During the Boer War camps of prisoners were erected in Ceylon and surrounded with very powerful arc-lamps so as to prevent any attempts of escape. In the first 4 to 6 weeks the moths came flying to the lamps in such enormous numbers that the poles of the lamps were all covered with them, mostly with specimens of *Deilephila hypothous* and *nerii*, but also with species of *Oxyambulyx*, *Marumba* etc. The white Noctuids from the genus *Sphettia* swarmed around the lamps in such great numbers that one had the impression of a snow-storm. Although immense numbers of all these common lepidoptera perished, such a great number of breeds must have developed and, above all, so many of the *Sphingidae* being so very fond of a roving life must have flown near the lamps that such a rapid decrease in their attraction to the lamps, as was then observed, cannot be explained by it. The fact of their having become accustomed to the light can only be considered with respect to the relatively small number of domiciled Noctuid species — to which the *Sphingidae* by no means belong — growing up in the immediate light of these arc-lamps. And even among these species it is not very probable that the larva sitting in the dense foliage and provided with a very slight visual power has become so indifferent to the accustomed electric light that after the subterranean pupal stage the imago reacts no more upon glaring lights. Thus, if we take no account of the cases in which the erection of plentiful and very extensive and powerful lighting — partly by the permanent diversion and destruction of numerous individuals, partly also by the mutual competition of the lamps radiating everywhere — in fact impairs the attraction to certain

bright lights, we are met here with a fact that is just as curious and puzzling as the almost regular non-appearance of lepidoptera in the moonshine.

The larvae of the *Sphingidae*, nearly all of which number among the most conspicuous insects, are also better known than those of the other families of *Heterocera*. Their shape has been described at large already in the volumes 2, 10, and 14, and we may therefore confine ourselves here to our knowledge of the American forms. Numerous forms parallel to the Indian Sphingid larvae are to be found in nearly all the subfamilies or tribes connecting the west with the eastern continents. They often resemble each other to such a degree that they exhibit the close relationship to species of the eastern hemisphere more distinctly than the imagines developing from them. Thus the larvae of *Herse cingulata* differ less from some of the palaearctic *H. convolvuli* than the latter do among their own forms. *Protoparce rustica* and *florestan*, excepting the granulated caudal horn and the shape of the oblique stripes meeting on the dorsum, are exactly like the Eurasian larvae of *Acherontia*; it is easily understood that also the larvae of *Smerinthus cerisyi* resemble most exactly those of the Eurasian *Sm. ocellatus*.

The neotropical region, however, also harbours numerous *Sphingidae* showing hardly any relations to the palaearctic members of this family, and the larvae of these forms also exhibit an appearance unparalleled in the Old World. Details about this will be found in dealing with the various species on the following pages; we merely mention here a few examples being of particular interest for their biological relations. So for instance there are Sphingid larvae in America showing the Geometrid manner of sitting, such as *Leucorhampha ornatus*. The resting insect holds itself with its claspers, on the one hand, and sometimes also besides with its pectoral legs, on the other hand, whilst the abdominal legs are drawn in; only in creeping the pectoral legs, especially the hindmost pair, are brought into action. If the larva is alarmed in this position, the protective attitude changes into a frightening attitude, the larva copying a snake's head.

The way the larva accomplishes this deception is so strange that it seems to make any other explanation of its behaviour in cases of disturbance impossible. The larva of *Leuc. ornatus*, during its Geometrid-like sitting position, exhibits an absolute protective colour; greenish or bark-grey, in the grown-up stage it represents a twig of a finger's length; the entire lack of feet — these being drawn in so far that they cannot be seen — very effectively intensifies the disguise into a lifeless piece of wood. On being discovered the larva persistently remains in this condition, also when it is gently touched; but as soon as it is more energetically disturbed, the insect changes its policy by erecting the front part of its body and turning it so that its underside is uppermost. In doing so it exhibits the exact image of a snake by a dark dorsal stripe (which extends across the ventral side of the larva), a broadly inflated occiput, the larva's head becoming pointed like a snout. The smoothly appressed pectoral feet copy part of the shielded scaly skin of a snake; two large squinting eyes on the underside of the 3rd or 4th segment, supported by the darting and wriggling motions of the raised larval body may even frighten sensible beings, because the swaying to and fro of the front body resembles the biting motions of venomous snakes and looks rather dangerous. In addition to this some specimens — most distinctly so the light greyish-green individuals — display an exact image of a transverse snake's mouth, i. e. a blackish transverse streak across the larva's head and the sides of the first segment. We do not even exaggerate in saying that the larva is able to change this "countenance", so that it "makes grimaces" to a certain degree. The *Leucorhampha* are very common, and when for instance one is searching the Apocynaceae on Mt. Corcovado near Rio de Janeiro, one will soon discover full-grown specimens, and nobody should then miss the opportunity of forcing the larva to show its tricks by disquieting it. The larva of *Leucorhampha* is indeed "the real arum", as the Rev. MILES MOSS says in his excellent work on the *Sphingidae*, and "one must have studied the wonder in the live insect in order that one may fully appreciate it".

Moreover, it must be considered that the larva only develops this disguise while it is growing. The larva of *Leucorh. ornatus* in its early stage looks somewhat like a young larva of *Smerinthus*. Its colour is green; the whole insect with its long needle-shaped caudal horn resembles the stalk of a leaf. On attaining the approximate thickness of a quill it copies a broken off branchlet, turns brown, and only when it has grown to the dimensions necessary for imitating a snake it assumes the snake-marking needed for the mimicry, when it promptly loses the anal horn which would interfere with such a disguise.

A most remarkable fact is that the larvae of each of the Sphingid species choose a special kind of disguise and are independent from each other in the development of their frightening images. The most closely allied to *Leucorhampha* mentioned above is *Madoryx pluto* Cr., the imago of which differs but very little from the somewhat larger *Leucorh. triptolemus*. Its larva in its early stage likewise resembles the young larva of *Leucorhampha*, and also later on it exhibits a resemblance to a twig and loses its anal horn, yet it inflates its anterior body in a quite different way forming a round knob; on being alarmed it does not turn itself round

but like a sphinx holds up its front end which is marked with a rather queer lateral eye not exactly imitating a snake, drawing its head completely in, instead of stretching it out as *Leucorhampha* does. A larva very similar to this is that of the genus *Oryba*. The larva of this bulky lepidopteron reaches the 4 or 5 fold volume of the preceding ones and, owing to its bulkiness, it has an effect entirely different from that of the slender *Leucorhampha* and *Madoryx*. The 5 foremost segments are transformed into a large mammalian head. The 4th segment is widely thickened laterally; a kind of rat's head with a crooked bridge of the nose and a very inflated cheek exhibits — at the anterior edge of the third segment of the larva — an angry-looking eye turned downward; its look has nothing to do with the ominous look of a snake, but it recalls the eye of the "Gambá" (Didelphys), i. e. the opossum being extremely dangerous to all the small living beings in America. This opossum is dreaded and shunned by all creatures — including man — in South America, on account of its fatal bites, its repulsive, half-naked exterior, and its horrible smell. No disguise more effective against small predatory animals could be fancied in the neotropical region.

The attempts to intimidate aggressive enemies may, however, sometimes be of quite different kinds. The anal horn which the larvae of the above-quoted genera lose before their pupation has grown in some species to a sting of 7 and more cm length, which is threateningly moved, though it is entirely inoffensive. The larvae of *Isognatus* while creeping never keep this tail-appendage — which is similar to the sting of a *Sirex* — quiet, but move it constantly up and down in a threatening and evidently automatic way, by which they would betray themselves at great distances to any person in search of them, if this were not already effected by their very bright exterior with its white, black and reddish longitudinal stripes. Here we may suppose that the sting is used against parasites, which, on settling on the larva, are pushed away with the anal thread which extends across the whole dorsum. The larva of *Isognatus* living on leaves allied with strophant, oleander and other strong poisons (Apocynaceae) needs just as little protection against insectivorous vertebrate animals as the milk-weed larva of *Celerio euphorbiae*; it is even likewise interested — as the equally poisonous larva of *Cel. nicaea* — in not being overlooked or mistaken; it has no frightening or warning colour, and as the Tachinae and Ichneumonidae are known to disregard warnings, they are whisked down from the larva's body by its extremely long tail-appendage. This warning colour and its effect form an interesting parallel to those of our European species of *Celerio*. In Goyaz and Araguay (Minas) I often found the extremely variegated, longitudinally striped larva of a species of *Isognathus* from the *Is. mossi*-group running up and down small poisonous trees of Apocynaceae in the hot sunshine, whereas the quite similar though not quite so variegated larva of *Isognathus allamandae* Clark living on the less injurious (even edible) *Allamanda cathartica*, according to Moss' observations, keeps hidden in the roots of its food-plant in the daylight. Thus it acts exactly like the *Celerio* of which the glaringly coloured poison-feeders *euphorbiae* and *nicaea* are seen by day moving agilely about on the food-plant, whilst the larvae of *C. gallii* or *C. vespertilio* living on unpoisonous plants (*Galium*, *Epilobium*) hide their less variegated and inconspicuous bodies during the day, or even, as the *C. hippophaes* living on the unpoisonous *Hippophaë*, adapts itself to the food-plant in the same excellent way, not betraying itself by any movement in daytime, as we have found it in the best adapted Sphingid larvae, such as *Marumba quercus*, *Amorpha populi* etc.

Whilst the green Sphingid larvae of the other continents — but also most of them in America — copy ribs of leaves by means of lateral oblique stripes, we know American *Sphingidae* the larvae of which have so excellently adapted themselves to their food-plant that the insect has become quite unrecognizable owing to the extreme plastic transformation of its larval shape; and even to a greater extent than in the development of red dorsal protuberances copying flower-buds of *Artemisia* exhibited in the larvae of palaearctic *Cucullia*. The larva of *Erinnyis lassauxi* Bsd. has been entirely transformed into an exact reproduction of a flower-stalk of the food-plant, an Asclepidea called "Angelica doar". These flower-stalks, on the coral having fallen off, represent themselves to the eye as a greenish stalk wound like a worm, the ends of which exhibit the growing placentae with two white pads each representing the dried milk of *Asclepias*. This peculiar formation has been imitated by a strange bend of the head-end of the larva, on which, above on the 3rd segment, the place of origin of the fallen blossom is designed and the poisonous milk of *Asclepias* imitated by two white guttiform protuberances. This marking is to be regarded as a distinct morphological violence, especially since the larvae of the closely allied species of *Erinnyis*, *E. alope* etc., do not show any formation out of which such a transformation might easily develop: *alope* has an almost black, cornigerous larva of the general Sphingid shape, being in no way adapted to its food-plant; its commonest food-plant is the melon-tree, *Carica papaya*, a Caricacea allied to the poisonous passion-flowers. The fruits of this tree may be eaten, but the milky juice of the leaves contains the very poisonous Papaine which instantly curdles fresh milk and presumably also other alkaline substances of the animal organism and softens the fibrous tissue of the animal body so efficiently that the Indians wrap up raw meat in the leaves of the melon-tree to make it delicate and to loosen the fibre-bundles from each other. Another food-plant of the larva of *Erinnyis alope* is the Cassava shrub, *Jatropha manihot*, which supplies the eatable tapioca, but which itself represents a strong poison; (by a

special process the poison is eliminated from the tapioca-flour which is to be found on every Brazilian dinner-table and especially on that of the poorer colonists). Thus the larva appears to be safe here, too, and therefore sits openly on the green food-plant as a very conspicuous object.

What bright colours American Sphingid larvae may assume, if they intend to display the warning colouring at great distances, is most obviously shown by the gigantic lepidopteron *Pseudosphinx tetrio*, the enormous larva of which — the largest I have ever seen *) — is black with yellow transverse rings, and rusty or brownish-red at both its ends. The effect of this very bright colouring is still more increased by the frequent clustering together of the larvae of *Ps. tetrio*, which behaviour is quite uncommon for Sphingid larvae. If, however, isolated larvae have settled on the bark of a ficus-tree, basking in the sunshine, they try to attract attention by "nervous convulsions", as MILES MOSS writes; this is an evident proof that they expect more safety from their being recognized than from their keeping in hiding. As the leaves and stalks of the figs contain a milky sap which has an inflammatory effect upon the mucous membranes, the immunity of the larvae from enemies may be due to the after-effect of the chyles. It must, however, be mentioned here that another explanation is possible; a resemblance between the Sphingid larvae and those of other families, which is hard to explain, does not exist in the whole world; the resemblance of leaf-imitating green larvae of all groups of lepidoptera, as between certain *Sphingidae*, *Endromis*-larvae, some *Noctuae*, or the thoracic eye and hornlet between *Bombyx*, is a matter of course by way of natural convergency. A case quite unparalleled in any other fauna, however, is the double of *Pseudosphinx tetrio* occurring in another lepidopteral family, i. e. *Arsenura cassandra* which shows an exact image of the uncommonly coloured larva being likewise black with yellow rings and coloured red at both its ends.

In most of the Sphingid larvae the caudal horn has the relatively greatest length on its emerging from the egg, becoming shorter as the larva grows older and finally disappearing altogether in some larvae. In the neotropical region, however, some larvae (*Isognathus*) preserve the (above-mentioned) uncommon length of their caudal horn until the last moult. Moreover, we notice the existence of 3 caudal horns in the early stage of *Isognathus*, since beside the usual one another pair of long stings rise on the anal plate. These paired stings are sometimes preserved until the third moult.

If our presumption that the *Sphingidae* — geologically spoken — belong to the Moths having only differentiated in recent periods, is correct, we cannot wonder at most of the larvae feeding on the more recent vegetable families. In dealing with the *Sphinges* from other faunas we have mentioned the genus *Leucophlebia* the larvae of which feed on grasses, thus on Monocotyledons. I know of no similar example in the American fauna. Mostly living on trees, they exhibit a frequently extensive versatility in choosing their food-plant without denying a marked predilection for certain kinds of plants. In the same way as our *Sphinx ligustri* shows a distinct inclination for syringes, ligustrum and ash-trees and, besides, is also to be found on a great number of inland and foreign ornamental shrubs, many of the otherwise polyphagous *Sphingidae* of America are especially attracted by a favourite family; thus for instance the *Protoparce* (corresponding in some measure to the palaearctic *Acherontia*) prefer the Solaneae, the *Herse* the Convolvulaceae, the *Protambulyx* the Anacardiaceae, the *Cocytius* the Anonaceae, the *Pholus* the Ampelideae, the *Xylophanes* the Rubiaceae, etc.

It is quite obvious that poisonous substances of feeding herbs which are still effectively contained in the undigested or half digested food of the larva must protect the larva from the persecutions of many enemies. It is a different question, however, whether these substances can be preserved during the pupal stage by the process of histolysis to such an extent that their protection even extends to the imago-stage. In Vol. X, p. 354, we have expressed the opinion that such cases are not improbable, yet we are induced to presume that the complete transposition of the organs and tissues generally also destroys this protective effect of the poisons of the food-plants. In fact, this seems to be the rule, and in districts of our earth abounding in *Sphinges*, particularly in the neotropical countries, most of the *Sphingidae* are choice delicacies for all kinds of enemies. When the *Sphingidae* come to the arc-lamps, they find them already encircled by crowds of hungry bats which snatch away the approaching lepidoptera with an audible crack. On the panes of the lanterns there are large and small geckos snatching fugitive *Sphingidae* even when they swiftly glide or run across the pane. The worst enemies, however, are the gigantic toads, occurring in immense numbers in the neotropical region, which most greedily and gluttonously swallow throughout the year whatever drops to the ground around the lanterns attracting the lepidoptera. The *Sphinges* are even snatched away from flowers by birds or small mammals; cats jump after them, and the day-flying species are exposed to the persecutions of the widely distributed tyrant-birds (Tyrannidae) among which the *Saurophagus*, having become a characteristic

*) More than 15 cm long, 3 cm thick, and 6 or 7 cm in circumference.

bird on South-American plantations by its cry "Bem-ti-vi" (I saw you well!), is stated by Moss to be a particular enemy of the *Sphingidae*.

The *Sphingidae* are of course in especial danger during their pupal stage, and it is to be wondered at that not all the *Sphingidae* descend far into the ground for their metamorphosis. Many Sphingid pupae are protected against the omnivorous ants by an extremely hard epidermis which is as smooth as porcelain, but we do not find this to be so general as in the close allies of the *Sphinges*, the *Ceratocampidae*, so that it is difficult indeed to understand why not all the somewhat rough-shelled Sphingid pupae are destroyed by the ants which are distributed throughout South America in almost devastating numbers. The biting organs of the ants ineffectually glide off the lustrous, hard shells of the pupae of the *Protoparce*, *Hyloicus* etc., but some species of ants provided with forcipated jaws and saws almost as strong as steel might find a hold for their maxillae on the delicate intermediate skins of certain *Madoryx* in South America or of *Haemorrhagia* in North America, so that one might think the pupal case to be provided with a property that is poisonous or repulsive to ants. Certainly the pupae perish unavoidably, even when the cuticle of the shell has only been slightly injured, in the same way as the hard beetles from the group of Passalidae and Dynastidae are immediately eaten out by ants, as soon as they come down to the soil towards the end of their life.

The exterior of the pupae is just as conformable in the *Sphingidae* as in other families. The pupae of the trunkless *Smerinthus* and *Pachysphinx* of course do not possess any protecting trunk-sheath which is also absent in the gigantic *Pseudosphinx tetrio* belonging to the *Sesiinae* in spite of its *Protoparce*-like shape. In *Cocytius antaeus* and *Euryglottis* the sheath is thick, bent down like a nose, but not yet spirally rolled up; this process only begins in *Herse cingulata* (the representative of the palaearctic *H. convolvuli*) and reaches its most perfect degree in *Cocytius cluentius* the pupa of which shows a trunk-sheath turning three times upon itself.

The American *Sphingidae* are classified according to the same principles as the groups of the Old World. The *Sphingidae asemanophorae* contain the only *Acherontiina* in *Herse cingulata* which has undoubtedly flown over only relatively lately; the *Sphingicae* are chiefly represented by the gigantic *Cocytius*, whilst they show the greatest abundance of individuals in the genus *Protoparce* the representatives of which are met with everywhere in the whole of tropical America. The *Ambulicinae* have genuine *Smerinthus* in the north and the *Cressonia* and *Pachysphinx* representing the palaearctic *Amorpha*; they are replaced in the south by the much more graceful *Protambulix* and *Amblypterus* which are provided with a functional proboscis. The *Philampelinae* or vine-hawkmoths attain either a considerable size or an abundance of species and individuals in the *Pholus*, the *Choerocampinae* in the *Xylophanes*. The extremely corpulent, clumsy *Pachylia* represent the *Sesiinae*, and gradually pass over to the smaller and more graceful shape of the *Pachygonia*, *Sesia* and *Haemorrhagia*; the *Macroglossum* of the Old World we mentioned above are replaced in their outward appearance by the *Eupyrrhoglossum*.

Family Sphingidae.

By Prof. Dr. M. DRAUDT.

T. Sphingidae asemanophorae (without a scent-patch inside on the basal palpal joint).

Subfamily: **Acherontiinae.**

1. Genus: **Herse** Oken.

This genus being more common in the Palaearctic and Oriental regions is of a robust build, of the usual Sphingid type. Proboscis very well developed, longer than the body; palpi regularly scaled. Pulvillus only traceable. Antennae of ♂ strong, of ♀ thinner, slightly thicker towards the end. Only 1 species in the American region:

H. cingulata F. (= *affinis* Goeze, *druraci* Don., *pungens* Eschsch.) (90 a) is similar to the palaearctic *cingulata*, smaller on an average, more slender. Forewing grey with a darkened median band which, however, does not extend to the inner margin, and with a brownish mixture before and behind the two double notched transverse lines, the posterior line being more intensely filled with white. Base of hindwing and the first 5 abdominal segments mostly of a very bright pinkish carmine. This red colour has almost entirely disappeared in — ab. **decolora** Edw. — **pallida** Closs refers to a pale specimen without any red at the base of the hindwing, with a shortened basal band uniting with the discal band at the inner margin. From Pennsylvania. *decolora*, *pallida*. It has a very extensive range and is probably found everywhere from Canada to Argentina, in the northernmost districts probably as a bird of passage. Also from the Galapagos and Sandwich Is. Larva very similar to that of *convolvuli* and just as variable; green, olive brown, or sepia, with 8 subdorsal longitudinal bands and lateral oblique stripes; on Ipomoea, hidden in the daytime. Pupa light brown with a free and reflexed case of the proboscis.

2. Genus: **Cocytius** Hbn.

Contains some of the largest *Sphingidae* known, especially the ♀♀ are often of a very considerable size. Separated from the allied genera by the bare, pointedly projecting last palpal joint. Proboscis often of an enormous length which may be almost 25 cm in *cluentius*. The abdominal segments bear more or less distinct scale-tufts above in the centre. Anterior tarsus with numerous short prickles outside on the first joint.

1. Group: Disc of hindwing not hyaline.

cluentius. **C. cluentius** Cr. (90 b) is the largest species. Forewing jet-black with a brownish ray in the prolongation of the cell to the margin and in the whole inner-marginal quarter, with double notched lines, the innermost line of which very obliquely bends inward almost to the base of the inner margin; 2 yellowish-white dots at the cell-end. Abdomen with 5 yellow lateral spots in distinction from the following species. Mexico to South Brazil and the West Indies. Larva green, finely haired, with 7 white oblique stripes uniting on the dorsum, laterally generally reaching hardly below the centre. On Anonaceae, occasionally also on Piper aduncum; pupa with a rolled up case of the proboscis.

beetzebuth. **C. beetzebuth** Bsdv. (= *godarti* Bsdv., *vivularis* Drc.) (90 d) is of a greener colouring basally and submarginally than the other species, with a green spot also outside and above the cellular dot. Hindwing neither with a transparent disc. Abdomen with only 3 yellow lateral spots. Nicaragua to Rio de Janeiro. Larva hitherto unknown.

2. Group: Disc of hindwing hyaline.

duponchel. **C. duponchel** Poey (= *jatrophae* Wkr., *vivularis* Btlr., *affinis* Rothsch.) (90 c) is a smaller species, likewise intensely mixed with green, abundantly intermingled with white scales, especially in the ♀ at the apex and the marginal area; the two black longitudinal rays below the cell and on its outside are very indistinct. The two white discocellular spots are sometimes enlarged and united to a crescent. Abdomen with small heaps of very distinct yellowish-white scales above, without a black longitudinal median stripe. Mexico to Bolivia and Southern Brazil, also Jamaica and Cuba. Larva very similar to that of *cluentius*, but the much less distinct oblique stripes obsolete above, and there is a dark dorsal line bordered with yellowish on both sides, without the fine hairs. Case of proboscis of the pupa shorter than in the other species. — In ab. **roseus** Gehlen, described according to 1 female specimen from Sa. Catharina, all the white spots and streaks of the forewing are pink.

mortuorum. **C. mortuorum** R. & J. Colouring and marking very similar to that of *duponchel*, but the black markings on the body and wings above are finer. Basal quarter of forewing with a strong white, partly interrupted line which is bent distally in the cell; the black longitudinal streaks in the disc are absent, the oblique apical line is very thin and interrupted. The thinly scaled place of *duponchel* is a loam-coloured and densely scaled area here. The yellow spot of the hindwing is lighter and only slightly sinuated. Genital apparatus very different. Expanse of wings: ♂ 57—60, ♀ 72 mm. Amazons (Rio Madeira) and South-Eastern Peru.

vitrinus. **C. vitrinus** R. & J. is likewise very near to *duponchel*. Body greyer above, lateral margin of thorax white, abdomen of a pure white beneath, the brown median spots very small, the lateral spots lighter yellow than in *duponchel*, the base of the hindwing also lighter yellow above and beneath. Forewing narrower, the interior angle less projecting, distal margin more convex; the green colour is replaced by white and grey, the 2 black streaks at the apex of the cell are elongated; the large white stigma is reniform, bordered with brown; the lines of the median area are more curved at the costal margin, the space between the 3rd and 4th lines ochreous on the veins, the 4th line very strong; the black oblique apical line borders on a white apical spot. The transparent area of the hindwing is much more extensive and extends from the base to the submedian fold. Expanse of wings: 58 mm. Cuba.

lucifer. **C. lucifer** R. & J. (= *morgani* Bsdv., *rivularis* Btlr.) (90 b) is similar to *duponchel*, larger and more slender on an average, more monotonously green without the white admixture, only the reniform discal spot and occasionally a small one above it are white; the 2 black longitudinal rays are very strong below the centre. Abdomen without the small heaps of yellowish-white scales, almost invariably with a strong black median line. From Mexico to Colombia and Venezuela, also taken in Pará. Larva not yet described.

macasensis. **C. macasensis** Clark is presumably most closely allied to *duponchel* and *lucifer*, but different from all the species known of *Cocytius*. Base of palpus light yellow, body brown above, abdomen laterally with 3 yellow spots, hair-tufts white at the base, abdomen light yellow beneath except the brown apex. Disc of hindwing hyaline, but not dentate outside between the veins. Forewing unicoloured dark brown above, all the markings indistinct, the black longitudinal streaks distinct but not very prominent; between the costal margin and the second median branch there are long red-brown postmedian diffuse markings which are expanded towards the margin; a dump-bell shaped yellow spot at the cell-end, a smaller and less distinct spot above it and somewhat more apical; fringe yellow, darkened on the veins. Hindwing dark brown above, yellow at the base. Length of forewing: 67 mm. Described according to 1 ♂ from Macas (Ecuador).

C. antaeus *Drc.* (= *caricae* Müll., *jatrophae* F.). A very large species, separated from all the species *antaeus*. with a hyaline disc on the hindwing by the marginal band projecting like a pointed tooth between the veins. Forewing without green with a lateral brown intermixture and a whitish strongly notched antemedian line. The nomenclatural form is the insular form from the Antilles (Jamaica, Nassau, Bahamas). The continental form: — **medor** *Stoll* (= *anona* Shaw., *antaeus* *Mschlr.*, *cluentius* *Troschel*, *hydaspus* *Cr.*, *tapayusa* *Moore*) (90 a) *medor*. is somewhat darker, mostly somewhat more variegated, with more intense black markings, the black marginal band of the hindwing projects more deeply and pointedly into the yellow basal spot in the inner-marginal spot. Florida to Southern Brazil. Larva with fine hair as in *cluentius*. Green with inconspicuous whitish oblique stripes bordered with a darker colour above, only the last stripe terminating into the horn is a broad white stripe; dorsal line violettish-red, bordered with white on both sides. It lives on *Anona cherimolia*.

3. Genus: **Amphimoea** *R. & J.*

Allied to *Cocytius* in a certain way, but separated by the last palpal joint being more square when looked at from above, and projecting scarcely farther than in *Protoparce*. The long terminal spur of the posterior tibia is half the length of the 1st tarsal joint; paronychium bilobate on each side; anterior tibiae without thorns. Only 1 species:

A. walkeri *Bsdv.* (= *staudingeri* *Drc.*, *magnificus* *Rothsch.*) (91 a) is probably one of the largest *Sphinxes* *walkeri*. beside *cluentius*. Forewing greenish-grey, disc of hindwing semidiaphanous. Abdomen with 4 yellow longitudinal stripes, the yellow lateral spots placed longitudinally. An evidently rare species, distributed from Nicaragua to Southern Brazil. Larva and pupa already figured by MERIAN, then by BURMEISTER; it is said to live on *Jatropha*.

4. Genus: **Protoparce** *Burm.*

A large number of species which are sometimes difficult to separate from each other, whilst others are of an entirely different exterior. Structurally similar to the preceding ones. Proboscis of about the same length as the body; end of palpus on a level with the frons, last joint very short; last joint of antenna long and thin. Paronychium with one lobe on each side. Larvae mostly provided with oblique lateral bands; they live on Solanaceae.

P. sexta *Johanns.* (= *carolina* L., *nicotianae* Mén., *lycopersici* *Bsdv.*) (91 a) is a very common species, *seata*. easily recognized, grey, partly strewn with brownish, mostly with an intense blackish darkening outside below the cell-end, and a white notched line close before the white-speckled fringe. Hindwing with 3 or 4 whitish transverse bands. Abdomen with large reddish-yellow subdorsal spots as far as the last segment and intense white punctiform spots above. ♂ usually of a more subdued colouring and more brownish than the ♀. The nomenclatural type shows a very prominent white submarginal notched band of the forewing, and the whitish bands of the hindwing are more or less shaded. It occurs from Canada down to Honduras. — **jamaicensis** *Btlr.* *jamaicensis*. (= *paphus* Mén.) is less bright and more brownish, the hindwing browner, mostly very difficult to separate from the type. Jamaica, Haiti, Cuba, and Bahamas. — **paphus** *Cr.* (= *nicotianae* *Bsdv.*, *tabaci* *Bsdv.*, *cestri* *paphus*. *Bsdv.*, *griseata* *Btlr.*) is the form chiefly distributed from Costa Rica to Argentina, generally with somewhat paler forewings, the white submarginal line less prominent, the light bands of the hindwing of a purer white. The larva occasionally lacks the black dots bordering on the oblique lines in the other races. — **caestri** *Blch.* *caestri*. (= *eurylochus* Phil.) is a small and very light Chilean form; the white submarginal line of the forewing is almost or entirely absent, the black discal line is more prominent on the light ground, in the same way as the white dots on the abdomen. — **luciae** *Gehlen*, from Sa. Lucia, is remarkably different from *jamaicensis*, small, *luciae*. prominently coloured and marked; forewing more yellowish-brown, not grey, the bands of the hindwing of a pure black with white spaces between. The yellow abdominal spots are dark orange, the black median band is very distinct. — **fuliginosa** *Closs* is a form with a very distinct light postdiscal line, from São Paulo, *fuliginosa*. more extensively suffused with a smoky brownish colour, probably found everywhere among the typical form. The larva is green, generally smooth, on the white woolly *Solanum grandiflorum*, but according to Moss also covered with fine hairs, with white oblique lines bordered by black dots above, and a reddish horn. It lives on all kinds of Solanaceae, such as tobacco, tomatoes, potatoes, Spanish pepper, etc. and transforms, in a spacious underground cave, to a mahogany-brown pupa with a long, not rolled up case of the proboscis.

P. mossi *Jord.* is near to *sexta*, especially to its form *caestri*, separated by thinner antennae, blacker *mossi*. palpi, and a pure white underside of the abdomen; the wings are more pointed, the white colour in the fringe predominates upon the black spotting of it; the blackish-brown darkening in the disc of the forewing is absent, also the blackish-brown submarginal band of the hindwing; body above of a purer smoke-grey colour, the collar mostly exhibits an olive yellow line instead of a black one; the yellow lateral spots on the abdomen are smaller than in *sexta* and have broader black borders. Genital apparatus very different. The green larva, very frequently covered with parasites, shows white oblique stripes bordered with darker above, and a dark dorsal line bordered with white, but interrupted at the posterior end of each segment. It lives on *Cestrum hediundinum*. Peru.

- afflicta*. **P. afflicta** Grt. (= paphus H.-S.) is very near to *sexta*, the forewings are more greenish grey owing to yellow scales being intermixed, the hindwing with but two distinct white bands, the marginal band intensely dusted with yellow. Cuba; Haiti; Amazons. — *bahamensis* Clark (91 b), founded upon one specimen from Nassau, is larger, greyer above, more intermixed with white, whereby it is more variegated, the scanty markings more intensely black. Larva green, with lighter green oblique bands, 2 light dorsal lines and white stigmata.
- quinquemaculatus*. **P. quinquemaculatus** Harr. (= carolina Don., celens Hbn., maculata Grt.) (91 b). A well-known species, recognizable by the hardly dentate subterminal band of the forewing showing a distinct and double black border. The light grey hindwing exhibits 2 sharply notched median lines before the broad black subterminal band. Separated from all the other species by the presence of some thorny bristles on the anterior tibiae. North America to Mexico; a somewhat deviating form occurs in the Sandwich Is: *blackburni* Btlr. in which the small triangular light postdiscal spots reach to the costal margin, which is mostly not the case in the nomenclatural type. — *wirti* Schs., according to a bred ♀ from Virginia, is a form with a much darker ground-colour, more reddish-brown, with hardly any white, only outside at the subterminal line and in the marginal line. Hindwing and ventral side chestnut brown. Larva similar to that of *sexta*, of a variable colouring: green, brown, or black, covered with many light dots, with a light interrupted longitudinal band below the stigmata. It chiefly lives on tomatoes and potatoes.
- dilucida*. **P. dilucida** Edw. (= indistincta Rothsch.) has much lighter grey brown forewings with distinctly contrasting white markings the scheme of which is exactly as in the preceding species. Antennae long and, particularly in the ♂, relatively thick. Abdomen with normally 4, rarely 3 yellow lateral spots. Pulvillus absent. An apparently rarer species, found from Mexico to Honduras. Larva not yet known.
- kuschei*. **P. kuschei** Clark is only separable by the different genital apparatus, the ♀ is more monotonously coloured, greyer, the white inner-marginal area of *dilucida* is entirely absent. Expanse of wings: 76—88 mm. Mexico, Sinaloa.
- lucetius*. **P. lucetius** Stoll (= contracta Btlr., hannibal Burm.) (91 c) is well characterized by a large blackish-brown crescentiform spot with a silky lustre at the costal margin of the forewing, contrasting with the otherwise bronze brownish or more olive grey ground-colour. Fringe only white-dotted on the vein-ends, but the white colour occasionally expands inwards, or it may also be absent altogether. Hindwing as in *petuniae*. Guiana, Peru, Brazil to Argentina. — *nubila* R. & J., from Costa Rica, has a somewhat longer shape of the wings and a less brownish colouring in the basal and discal areas, the black postmedian line less curved. Costa Rica. — *panaquire* Berg (= argentina Clark) makes a more variegated impression owing to the very light brownish colouring around the dark costal marginal spot. The yellow abdominal spots are very bright orange and larger than in *C. lucetius*. From Tucuman (Argentina) and Bolivia. The early stages seem to be unknown.
- reducta*. **P. reducta** Gehlen is closely allied with *lucetius*, but it has narrower, more elongated and pointed wings, and thinner and shorter antennae. Head and thorax lighter than in *lucetius*. Collar with a black median stripe. Abdomen above similar as in *Clarki*, white beneath with scanty small brown hairs. Forewing lighter and greyer above, not so reddish as in *lucetius*, basal area with hardly any marking, the discal macular band straighter, not so much excurved, the area before it lighter, the postdiscal undulate line steeper, more parallel to the distal margin and not so undulated. Hindwing differs from *lucetius* only in the shape, apex more pointed, anal spots more projecting. The 1st joint of the posterior tarsus is longer than in *lucetius*, the anterior tarsi have longer spines. Peru (Huayabamba).
- diffissa*. **P. diffissa** Btlr. (= cestri Bsdv., petuniae var. Bsdv., diffusa Drc.) is intensely brown on the forewing, the notched transverse lines are not distinctly prominent on the irrorated ground; the postmedian lines are more angular below the centre. A white, black-edged dot at the cell-end. The black hindwing is grey at the margin and shows 2 whitish bands. The nomenclatural type is a small light form with a distinct black postmedian line. Argentina and Paraguay. — *petuniae* Bsdv. (= diffissa Ky.) is tinted somewhat more reddish-brown, but variable in the colour. From Sa. Catharina, Rio de Janeiro, Minas Geraes. — *tropicalis* R. & J. (= *lucetius* Rothsch.) is the common form with darker and less yellowish forewings, likewise rather variable, but never so light as *petuniae*. From Minas Geraes to the north as far as Colombia and Ecuador. — *ochracea* Clark is distinguished by its light ochreous ground-colouring on which the black markings are very prominent. Buenos Aires. — *mesosa* R. & J. is intermediary between *diffissa* and *petuniae*, as dark as the latter, but less reddish-brown on the forewing. North-Argentina. The larva is green with 7 white oblique bands bordered with black dots above, with 3 blue dots each around the white stigmata; the horn is pink. The form *petuniae* is said to have dark red oblique bands edged with dark red; it lives on Cestrum.
- occulta*. **P. occulta** R. & J. (= *lucetius* Drc., *petuniae* Drc.) (91 c). The exterior of the imago is the same as that of *diffissa*, only the forewing is somewhat broader on an average. Genital organs very different from those of *diffissa*. Only known from Central America (Mexico to Panama). Larva of a bright green with little yellow

tubercles on the first 3 rings; laterally 7 white oblique stripes confined to but 1 segment, whereas in *diffissa* they extend over two segments; the long green horn is granulated reddish.

P. hannibal Cr. Well characterized by the narrow bone-coloured marginal area in contrast with the *hannibal*. dark brown forewing the proximal border of which is not notched. Distributed from Panama to Sa. Catharina. — **hamilear** Bsdv. (= mayi Clark) (91 e) has a still more conspicuous light, almost white margin; the distal *hamilear*. band of the hindwing is of a purer white, less dusted blackish. Under surface darker and more distinctly marked, with a more dentated postmedian band. Genitally also somewhat different. Rio de Janeiro. Larva green, turning blue towards the ventrum, the first 3 segments thickened, lighter yellowish green, set with small reddish-yellow tubercles, the other segments with 7 white oblique stripes strongly widening below; horn bent, long, very much granulated. It lives on Solanaceae and Verbenaceae.

P. leucoptera R. & J. is light greyish-white above, with a white stigma, slightly shaded with brownish *leucoptera*. only submarginally, with a brown notched subterminal line and an oblique apical line. Hindwing greyish-brown, browner at the margin, with a blackish irregular postmedian band before which there are yet 4 quite indistinct bands. Only 1 ♀ (length of forewing: 45 mm) known from the Galapagos Is.

P. pellenia H.-S. (= capsici Bsdv., morelia Drc.) (91 e). Forewing mixed with lighter and darker *pellenia*. brown, with a large slaty blackish spot in the disc, reaching to the costal margin where it encloses — more distinctly so in the ♀ — an oblong light brown spot. The whitish yellow notched submarginal line reaches the apex more distinctly in the ♂ than in the ♀. Abdomen scaled brown beneath. Mexico, Panama, Colombia. — **janeira** Jord. is smaller than the type, abdomen almost purely white beneath, with broader forewings *janeira*. than in *scutata brasiliensis*. Basal and apical areas of both wings distinctly more variegated, the grey band of the hindwing shaded with dark brown; genitals somewhat different. Rio de Janeiro.

P. perplexa R. & J. resembles *pellenia* in the colour and marking; head and palpi of a blacker colouring, *perplexa*. abdomen lighter beneath, basally all white. Forewing broader, and darker in the costal-marginal area than in *pellenia*; the black spot with a silky lustre is longer and more incurved between R³ and the costal margin. The light discal band on the hindwing is intensely dusted with black, and the black submarginal band narrower than in *pellenia*. Hindwing darker beneath, only the inner-marginal area greyish-white, the blackish-brown dentate discal line is single. Genital apparatus somewhat different. Amazons (Rio Madeira). The very conspicuous larva is quite black, the 3 first segments set with yellow pointed tubercles, horn yellow; it lives on Solanum and Verbenaceae.

P. scutata R. & J. (= pellenia Mschr., pellenia Rothsch.) is not to be separated externally from *scutata*. *pellenia*, as *occulta* from *diffissa*, but the genital organs are so very different that it cannot even be a subspecies. Only the basal and marginal areas are somewhat less yellowish-brown, the whitish bands of the hindwings are somewhat smoky, the abdomen not scaled brown beneath. The two species occur together in Colombia. Besides known from Venezuela and Ecuador. — **boliviensis** Clark forms a transition to the following *boliviensis*. form. It is smaller and lighter: ground-colour light grey, the slaty grey macular band with its silky lustre is much narrower than in the other forms, the whole wing more monotonous, without the brown and white mixture; the white submarginal band of the hindwing is nearer to the margin. Bolivia. — **brasiliensis** Jord. *brasiliensis*. is a small form, greyer above than the nomenclatural type, but less so than in *tucumana* which represents *scutata* in Argentina; the black discal spots are shorter, the median band of the hindwing broader, the black spots on the abdomen beneath smaller. To a certain degree it also resembles *hannibal*. Rio de Janeiro. Larva bright green above, more bluish green beneath with white oblique stripes, the 3 first segments with small yellow tubercles; feet ochreous and black; it lives on Dasura.

P. clarki R. & J. is very similar to *perplexa*, *scutata* and *pellenia*, the most closely allied to *perplexa*. *clarki*. Smaller, the light areas on the thorax and wings grey without a reddish-yellow tint and therefore of a very different exterior. Antennae thinner than in the 3 species mentioned; frons and occiput black; the small white dorsal spots on the abdomen are very indistinct, the 7th segment without the yellow lateral spot; the white ventral side scaled brownish-black, only the 1st segment pure white, the black ventral spots small, mostly only one present. Legs black, scaled white. Hindwing beneath with a black median band composed of 3 lines. Genital organ very different from that of *perplexa*. Length of forewing: 41—48 mm. Only few specimens known from the Amazons (Fonteboa); Ecuador; Peru.

P. tucumana R. & J. looks like a small pale *pellenia*; the cell-end spot and the light lines of the fore- *tucumana*. wing are greyish white, not yellowish. Genital organs very different. Argentina and Paraguay.

P. oclus Klug (= instita Clem.) (91 e) is unmistakable for its brownish-yellow, peculiarly marked *oclus*. forewing with the 3 large costal-marginal spots which are scaled slaty blue. Thorax likewise tan-coloured. Mexico to Venezuela and Colombia.

P. lefeburei Guér. (91 b) is likewise hardly to be mistaken. Ground-colour whitish-grey, a dark brown *lefeburei*. band extends from before the centre of the inner margin, crossing the white discal dot, to the margin on vein 2, and together with another triangular costal-marginal spot farther outside it forms a triangle which is generally

edged with light brownish; antemedian line indistinctly whitish, the feeble postmedian line notched. Hindwing brownish black. Mexico to Southern Brazil. — **bossardi** Gehlen (91 d) refers to Eastern Mexican specimens (Veracruz) in which the ground-colour is of a much brighter cinnamon-reddish tint, with reduced markings of a dark cinnamon-brown colour; hindwing whitish yellow with a reddish-brown distal margin and similarly scaled veins. Vera Cruz.

incisa. **P. incisa** Wkr. is very similar to *lefeburei*, but separated from it by the presence of a strong black dorsal line on the abdomen, which is always absent in *lefeburei*; moreover, the proximal half of the forewing is lighter than the apical half; the black discal streak extends parallel to the veins and thus forms an angle with the costal portion. The exterior transverse lines are stronger than in *lefeburei*. Genital organs different. Amazons, São Paulo, Matto Grosso, as far as Paraguay.

andicola. **P. andicola** R. & J. is darker than *incisa*, the black markings broader and stronger, the black dorsal line on the abdomen also broader, but less prominent owing to the darker total colouring. 3 interrupted angled transverse lines in the basal half of the forewing, which is lighter than the apical half, and farther towards the margin a distinct postdiscal line composed of arches and small double spots; deeper brown beneath. The thorns on the 1st joint of the anterior tarsi are shorter than in *incisa*. On account of the genital differences it is better regarded as a distinct species than only a representative of *incisa* from the Andes. From the Andes to Peru and Ecuador.

prestoni. **P. prestoni** Gehlen (91 e) has a marking similar to that of the two preceding species; ground-colour monotonously brownish grey without the yellowish colouring and with little white; transverse bands on the forewing almost extinct, the interior half of the wing not lighter than the distal one, the blackish-brown longitudinal streak in the disc thin and distinct; base of forewing contrastingly pure white, like the large distinctly edged stigma. Hindwing black, costal margin, base and inner margin light yellow. Metathorax with white hair-tufts. Abdomen with 3 large yellow lateral spots, ventral rings with 2 white small apical spots each without a median line. Amazons (Manicoré). We are able to figure the type by the kindness of the author.

stuarti. **P. stuarti** Rothsch. (90 e) is the only species with yellow abdominal spots, but the second segment without them. Frons lavender grey, palpi yellowish with a deep black dorsal margin. The light brownish-grey forewing is intermixed with yellow scales, with black dentate lines, lighter whitish behind the cell, and two white black-edged discal spots at the cell-end. Hindwing darker than forewing, blackish-grey with 3 postdiscal and submarginal black notched transverse bands. Only known from Bolivia. Early stages not described.

manducoides. **P. manducoides** Rothsch. (= breyeri Köhler) (90 b) is a very conspicuous species, somewhat like *rustica*. Forewing deep black with 3 broad pinkish whitish bands traversed by black dentate lines, the two distal bands of which are connected at the inner margin by a broad whitish longitudinal band, and with a whitish stigma. Hindwing white with a blackish-brown marginal band and two narrower transverse bands before it. Abdomen black mixed with white, with 3 light yellow lateral spots. Chiquitos (Bolivia); Brazil.

viola-alba. **P. viola-alba** Clark (90 d) is a beautiful and very uncommon species, dissimilar to any other species, but somewhat allied to *manducoides* owing to the white colour of the hindwing. Body dark brown above, strewn with violet, abdomen with 4 rectangular yellow lateral spots, the 5th segment bears a white lateral spot, under surface strewn with white and yellow. Forewing dark violet above, with 4 irregular dark brown transverse lines which are dentate on the veins, and 4 dark brown submarginal spots on the veins; a dark brown oblique apical line cuts the 4th transverse line. Hindwing white above, somewhat pink at the inner margin, with a dark brown marginal band of 4 mm width, slightly intro-angular on the veins as well as on the inner-marginal fold. Length of forewing: 39 mm. According to 1 ♀ from Matto Grosso, Western Brazil.

brunalba. **P. brunalba** Clark is likewise allied to *manducoides*. Palpi brown with a white basal joint, head and thorax brown, tegulae bordered with black and white, with a yellow line between; abdomen light brown above, strewn with white, purer white between the segments, with a brown median line, 5 yellow lateral spots, the two distal ones less distinct; under surface white. Forewing above light brown, strewn with white, the trapezoid stigma pure white; median area almost crescentiform, brown, the base 2 cm long at the costal margin, somewhat lighter in the centre, extending almost to the inner margin, distally bordered by a white line; from the inner margin proceed 4 feeble light brown lines disappearing in the brown area; proximally to it, at the inner margin, a white transverse band 3 mm broad, not quite reaching the costal margin; the black apical streak is strong and 16 mm long; fringe speckled white between the veins. Hindwing dark brown above with a white submarginal band disappearing towards the costal margin; a white spot at the inner margin extends from the anal angle. Length of forewings: 50 mm. According to 1 ♂ from Cuyaba, Matto Grosso.

rustica. **P. rustica** F. (= chionanthi Abb. & Sm.) (92 a) is a very common large species, black, more or less intermixed with olive yellowish scales, and with 2 broad whitish transverse bands, traversed by black dentate lines and filled with a somewhat olive yellow colour, especially the distal one which is darkened towards the inner margin and connected with the antemedian one by whitish colouring at the inner margin. Hindwing blackish-brown with a whitish postmedian band and anal spots. If the yellow scales turn yellow or golden

auriflua. brown and are increased, we have — **auriflua** Gehlen, a rather common individual form, before us. In the whole of America excepting the extreme north and north, from New York to Buenos Aires; Bahamas; Haiti;

Jamaica. The race — **harterti** *Rothsch.* (= *rustica* *Snell.*), from the Lesser Antilles and Curaçao, scarcely differs, *harterti*. but the dark costal-marginal triangle is always distinctly lighter. — In **cubana** *Wood* the dark parts of the *cubana*. forewing are brown, not black, the central area is uniformly connected with the dark distal margin. — **domini-** *dominicana*. **cana** *Gehlen* is a still larger form with more slender wings, the upper surface and the body more extensively and purely white; the dark areas are not brown as in *cubana*, but black; the white spots of the hindwing are larger; S. Domingo, Haiti. — **postscripta** *Clark* is distinguished by more intensely marked hindwings of a lighter *postscripta*. ground-colour, with more distinct black transverse bands. The finely granulated lightgreen larva is more whitish above and has 7 white oblique bands which are bordered with dark green or violettish-red above; it lives on *Chionanthus*, *Bignonia* etc. It also occurs in a dark purple brown variety; before the pupation it turns dirty pink and covers itself with a foamy sticky substance like some other species of the genus. It pupates in a spacious underground hollow.

P. calapagensis *Holl.* The only type known is a distinct species and not a subspecies of *rustica*. Ground- *calapa-* colour more chalky white, chiefly on the thorax and the abdomen above; a uniformly bent thick black line, *gensis*. 6 mm long, laterally on the patagia. Wings differently shaped, the interior angle of the forewing being obtusely angled, above and below it the distal margin and inner margin are slightly concave, the distal margin convex towards the apex. All the rest as in *rustica*. Galapagos I.

P. nigrita *R. & J.* is likewise a distinct species and not an aberration of *rustica*, as the authors presumed. *nigrita*. 5 quite similar specimens are hitherto known. The lateral abdominal spots are white, not yellow. The transverse band of the hindwing is not dentate beneath, but coherent and rectilinearly defined. Strictly separated from *rustica* by the different genital organ. The larva lives on *Erigeron lancifolius* and *Croton scouleri*.

P. albiplaga *Wkr.* (= *cluentius* *Burm.*, *rustica* *Burm.*, *trojanus* *Schauf.*, *valida* *Boisdv.*) (92 a) is some- *albiplaga*. what similar to *rustica*, but the two white transverse bands are reduced to 2 large, indistinctly bordered antemedian and subapical spots and not traversed by distinct but only blurred shadowy lines; a small white costal-marginal triangle is above the distinct white discal dot. Mexico to Southern Brazil. The bluish-white larva has 8—10 lateral bright yellow spots bordered with black, and black belts interrupted above on each ring behind. It lives on *Boraginaceae* and *Anona*, mostly in small numbers together. — **exacta** *Gehlen*, according to 1 ♂ from *exacta*. Matto Grosso, shows a more extensive and purer white which is also more distinctly defined against the dark areas; the anal-angular spot of the hindwing and the 1st abdominal ring are also more extensively and purer white.

P. trimacula *R. & J.* is closely allied to *albiplaga* and also to *dalica*. Colouring and marking somewhat *trimacula*. like that of *rustica*, the white colour of *albiplaga* is confined to 3 submarginal spots at the anal angle, above the centre and above the apical oblique streak, and besides a small spot in the postmedian line below the costal margin is white, too. Hindwing with quite obsolete lighter band-markings. Colombia (Cauca and Rio Dagua).

P. leucospila *R. & J.* exhibits a colouring between *rustica* and *dalica*, with narrower wings. Abdomen *leucospila*. as in *rustica*, but more intermixed with white scales towards the end. Forewing similar to that of *rustica*, a triangular costal-marginal area before the stigma, the fillings in the antemedian and postmedian lines partly somewhat lighter reddish-yellow, a large apical spot, an anal spot, and the notched submarginal line white. Hindwing similar to that of *dalica*. Peruvian Amazons.

P. dalica *Ky.* (= *garleppi* *Rothsch.*) (92 b) is very closely allied to the preceding species and well charac- *dalica*. terized by a large white triangular spot at the costal margin above the white stigma; ground-colour more purple brown; a broader white subbasal band. Known from Costa Rica, Peru, and Colombia. — In **anthina** *anthina*. *Jord.* the ground-colour of the forewing is light brown from the white subbasal markings to the thick black postdiscal undulate line, scarcely shaded darker between the discal lines and the postdiscal line. Rio de Janeiro.

P. brontes *Dru.* (= *pamphilius* *Stoll*, *collaris* *Wkr.*). This species introduces a group of closely allied *brontes*. forms that are sometimes difficult to separate; all are more or less whitish-grey with black dentate lines; *brontes* is characterized by a brownish-black collar and a black spot bordered with rusty red, on each side of the metathorax. Veins 2 and 3 not striped black. In the ♂ of the nomenclatural form the postdiscal area and a stripe above the distal half of the inner margin is tinted reddish-yellow, in the ♀ the tegulae, the basal and marginal areas of the forewing, and an anal-angular spot of the hindwing are whiter than in — **cubensis** *eubensis*. *Grt.* (= *brontes* *Luc.*), from Cuba, Bahamas, Porto Rico, and South Florida, which is somewhat more distinctly marked black besides. The nomenclatural type is from Jamaica. — **haitiensis** *Clark* (92 c) is intermediate *haitiensis*. between *brontes* and *cubensis*, but nearer to *brontes*; the black markings are less intense than in *cubensis*, the colouring is darker and more unicoloured than in *brontes*, the reddish-yellow spots are absent. Haiti. — **smythi** *smythi*. *Clark* (92 d) has much broader wings, the colouring is much more yellowish or brownish, the markings are dark brown. Porto Rico. The larva of *brontes* is very much like that of *sexta*, with the same oblique lateral bands, but the spiracles are bright orange.

- sesquiplea*. **P. sesquiplea** *Bsdv.* (= *strix* *Bsdv.*) (92 d) is closely allied to the better-known *muscosa*, but larger, with somewhat narrower wings and a whitish-grey not olive grey ground-colour, the antemarginal bands filled with more blackish above the inner margin; genital organs very different. Only known from Mexico and Guatemala. — **opima** *R. & J.* is a much more decidedly greenish form, with longer wings than in *muscosa*, the ♂ antennae thicker; the thorax bears a narrow black lateral line, and the black submarginal band of the hindwing shows a more uniform proximal border. Much darker than Mexican *sesquiplea* which is whitish-grey above; the two black median bands on the hindwing are much nearer together and the transverse lines on the forewing are stronger. Costa Rica.
- muscosa*. **P. muscosa** *R. & J.* (= *sesquiplea* *Drc.*) (92 b) has remarkably broad wings of a dark olive grey colour with numerous black dentate bands and very dark hindwings in which the lighter bands are scarcely prominent. Mexico to Costa Rica.
- bergi*. **P. bergi** *R. & J.* is somewhat like a small, light and narrow-winged *muscosa*, of a much lighter and more yellowish ground-colour; as to the black transverse bands, two of them, an antemedian one and one extending through the centre, are more prominent, the others being quite blurred and indistinct; stigma absent. Argentina (Tucuman).
- bergarmatipes*. **P. bergarmatipes** *Clark* is intermediate between *bergi* and *armatipes*, but the genital organs are reported to be identical with those of *bergi*. The first palpal joint is white, the following joints are much intermixed with black. Thorax reddish fawn, tegulae ash-grey, bordered with brown; abdomen without the white basal hair, ash-grey above, white beneath with 2 small black median spots. Forewing light reddish-yellow above, less mixed with white than *armatipes*, marking very similar, but less distinctly prominent than in *armatipes*, and much more intense than in *bergi*; stigma crescentiform, but smaller and less distinct than in *armatipes*, the dark submarginal area is absent. Hindwing black above, darker than in the two other species, the white double median line is distinct anally and broader than in *armatipes*, vanishing towards the costal margin. Inner margin yellow. Length of forewings: 45—47 mm. 2 ♂♂ from Tucuman (Argentina).
- armatipes*. **P. armatipes** *R. & J.* (93 a) is very similar to *lichena*, but smaller and easily separated by 4 or 5 long spines on the 1st joint of the anterior tarsus, and a similar apical one on the 2nd joint. Colour and marking almost exactly as that of *lichena*, but the basal area of the hindwing above is more extensively grey, the black median band more distinct; transverse lines of forewing strongly developed and sharply dentate. Colouring very much like that of *Chlaenogramma undata* which, however, shows 2 black longitudinal streaks in the disc of the forewing. North Argentina (Tucuman).
- carrerasi*. **P. carrerasi** *Giac.* (92 e). This peculiar species which we figure from a water-colour sketch kindly placed at our disposal by the author, is compared with *bergi*. Ground-colour yellowish pink, abdomen above coal-black excepting the two first pinkish carmine segments, intermixed with single pink hairs. Antennae pink above, blackish beneath, face, palpi and legs black, forewing with 4 blackish dentate lines, the two first nearing each other, the third being the strongest and rather near to the fourth, between the two latter a brighter pink parallel line; all the rest as in *bergi*. 1 ♀ from La Rioja (Argentina), taken in spring.
- corallina*. **P. corallina** *Drc.* is so much like *lichena* externally that these two species flying at the same place are difficult to separate, except by the genital organs. *corallina* has somewhat longer and narrower wings than *lichena*, the tarsus is without a pulvillus. The white apical spot of the forewing bordered by the black oblique streak below is very distinct. Only in Central America: Mexico to Honduras. — **extrema** *Gehlen* (90 c) has a darker ground-colour with more contrasting markings, with more oblique and less curved transverse bands which are darkened in the basal third, with a yellowish postdiscal transverse band. Bolivia (Rio Songo).
- lichena*. **P. lichena** *Burm.* (= *rufescens* *Btlr.*, *brontes* *Rothsch.*, *corallina* *Rothsch.*, *florestan* *Bönnigh.*, *pamphilius* *Burm.*, *schausi* *Clark*) (92 e) is a large strong species, profusely intermixed with greenish-yellow scales, the basal and median areas darkened especially in the ♀, with a white stigma. Hindwing deep blackish-brown, anally lighter, so that the black dentate transverse lines are more distinct. Tarsi with a pulvillus. Larva green, granulated yellowish with narrow pink lateral oblique stripes. Distributed from Mexico to Argentina.
- florestan*. **P. florestan** *Stoll* (= *brevimargo* *Btlr.*) (92 d) is not separable from *lichena* structurally, but generally smaller, more unicoloured, with finer and duller markings, not so intensely darkened, the black streaks stronger on veins 2 and 3; mostly tinted reddish-brown distally to the stigma. Hindwing lighter and more brownish. Larva with broad white oblique bands narrowing down dorsally. Mexico to South Brazil.
- vestalis*. **P. vestalis** *Jord.* is much purer white than *florestan* which it resembles most. The black lateral spots on the abdomen are narrow and not contiguous above, so that the white spots directly pass over into the grey dorsal colour. Forewing marked as in *florestan*, the black basal stripe broader, the margin before the anal angle

more deeply incurved; the two discal streaks are distinct, submarginal line quite indistinct, the space between the 2nd and 3rd lines almost pure white; basal and discal areas tinted yellow in the type. From the base of the hindwing to the anal angle a broad whitish-grey area extends, crossed by 3 black transverse lines and 2 black streaks. Genitals similar to those of *florestan*, but the 10th sternit shorter and broader, the harpe less dentate and double-knóbbed dorsally. Length of forewing: 58—60 mm. Pará in May and June, according to 2 ♂♂.

P. fosteri *R. & J.* is very similar to *lichena*, but the forewings are narrower than in *lichena* and *fosteri*. *florestan*; the spaces between the black lines are purer white, the black longitudinal streaks longer in the disc; the subterminal line is expanded into a large triangular spot at the costal margin, and the space between this spot and the oblique apical line is whitish tan-coloured. Hindwing more oblong, white from the base to the 1st band except a large brownish-black spot between the cell and inner margin, the space between the 3 black bands at the costal margin distinctly white, then gradually more dusted brown. Genital organs different. From Sapueay (Paraguay), 1 ♂ taken in January.

P. lanuginosa *Edw.* (= *collaris* *Edw.*, *corallina* *Drc.*) (92 c) is likewise very similar, but much more *lanuginosa*. monotonous and greyer, scarcely mixed with white, it especially also lacks the white apical spot above the black oblique streak. Neither separable from the two preceding species in structure. Mexico to Honduras. A slightly darker form is — **hoffmanni** *Clark* (93 a) from Misantla. *hoffmanni*.

P. crocala *Drc.* (93 a) is marked like the preceding species, but of a warmer brown tint and easily *crocala*. discernible by the hindwing being grey in the basal third, strictly contrasting with the brown distal portion. Apparently very rare, from Guatemala and Honduras. — **tepici** *Clark*, from Tepic (Mexico), is of a greenish tint, *tepici*. not brown, the broad postmedian transverse band darkened; the grey basal portion of the hindwing is narrower.

P. franciscae *Clark* (93 b) resembles *florestan*, but it is much lighter whitish-grey, without the greenish- *franciscae*. yellow tint, marked lighter and darker blackish-brown, hindwing lighter brown, more extensively white at the anal angle. Smaller on an average than *florestan* and with narrower wings. Venezuela.

P. barnesi *Clark* (93 b, c) is likewise most closely allied to *florestan*, with still narrower wings than in *barnesi*. *franciscae*; ground-colour likewise whitish-grey, more bluish ash-grey, especially in the ♂ often with a somewhat greenish tint before the postdiscal bands; the black streaks on veins 2 and 3 are entirely absent. Hindwing still lighter brown than in *florestan*. Described from Guatemala, also from West Mexico (Colima).

P. corumbensis *Clark* also belongs yet to this group. The whitish ground of the forewing is densely *corum-* strewn with brown, marked like the allies, the two bands enclosing the median area with the white stigma *bensis*. as well as a subterminal line are very prominently dark; veins 2 and 3 with thick black stripes. Hindwing dirty white at the base, with a blackish-brown basal spot and median band, the two distal thirds grey with a broad brown subterminal band. Matto Grosso.

5. Genus: **Chlaenogramma** *Sm.*

Very near to *Protoparce*, separated by smaller eyes and the absence of the thorny bristles on the middle tarsi. Especially *Chl. jasminearum* is closely allied to *P. florestan* from which it can be hardly distinguished, and a remarkable fact is that the genital organs of these two species are identical.

Type: *jasminearum* *Guér.*

Chl. jasminearum *Guér.* (= *rotundata* *Rothsch.*) (93 c) is externally very similar to *P. florestan*, the *jasminca-* anal angle of the forewing projects somewhat less; the upper one of the two black submedian streaks extends *rum*. to the postmedian line or almost to the margin, the lower one being indistinct. Georgia to New England, to the west as far as Pennsylvania and Canada. Larva light yellowish-green with 7 narrow white lateral oblique stripes, the last bordered with red and green anteriorly; on ash-trees.

Chl. undata *R. & J.* has longer spined anterior tarsi than the preceding species; forewing yellowish *undata*. grey or grey dusted with brown with more distinct dentated transverse lines, the nomenclatural type with a loamy tint, very distinct transverse lines, with large brown spots on the abdomen beneath. The patria of the type: "Costa Rica" may be doubtful. — **cinerea** *R. & J.* is of a purer whitish-grey, the black markings less *cinerea*. distinct, the marginal band of the hindwing broader, the spots of the ventral side smaller. Argentina.

Chl. obscura *Clark* (93 c, d) is smaller, darker and with narrower wings, more brown with white irro- *obscura*. ration, the markings very similar to those of *undata*, the antemedian line stronger, the marginal area more darkened analwards. Argentina.

Chl. muscosa *Jones*. Body olive grey, tegulae bordered with white, on each side of the abdomen *muscosa*. a series of triangular black lateral spots, ventral side yellowish-white. Forewing yellowish-white, strewn with

olive and black; the double black anterior transverse line is introangular on the submedian fold; 4 black undulate-dentate postmedian lines, the 1st and 3rd space between them filled with olive green, the 2nd with yellowish-white, all 3 strewn with black; a black dentate stripe extends from the subterminal line between 6 and 7 to the apex; the white discal spot is encircled with black, its surroundings are darker than the rest of the wing; fringe yellowish-white, spotted black on the veins. Hindwing whitish ochreous, dusted with black at the base and margin, with a broad faded black postmedian band which is excurved at the anal angle. Expanse of wings: 115 mm. Curitiba, Paraná.

6. Genus: **Euryglottis** Bsdv.

Likewise similar to *Protoparce*, separated by the thorax and legs being clothed with long erect hair-scales; pulvillus absent. 4 species from Tropical South America.

Type: *E. aper* Wkr.

- albstigmata*. **E. albstigmata** Rothsch. (93 d). Forewing velvety black with irregular short, lighter blackish-brown transverse streaks, densely scaled violettish-grey, with a large round yellowish-white stigma. Hindwing brownish-black, with violettish-grey bands and dusted with this colour, the ♀ with white; the black thorax with reddish hair, the black, grey-haired abdomen with 5 round orange-yellow spots on each side. Colombia, Ecuador and Peru. — *basalis* Rothsch., from South-Eastern Peru (Carabaya), is distinguished by the hindwing being all white from the base to the first discal line.
- dognini*. **E. dognini** Rothsch. (= *aper* Bsdv.) is very similar to the following *dauidianus*, larger, easily discernible by entirely white abdominal spots; the transverse markings of the forewing are slightly visible, the antemedian ones are quite extinct. Ecuador, Colombia, Venezuela.
- dauidianus*. **E. dauidianus** Dogn. (93 e). Black, with fine yellowish-white veins, 2 almost straight transverse bands, a yellowish-white discal spot and distinct subterminal dentate line. Hindwing blackish with a whitish transverse band. The median row of the abdominal lateral spots, which are often very small, is yellow. Loja, Ecuador. Larva bluish-green with 7 white oblique lines bordered with dark green above; head and caudal horn emerald-green, the head with 2 yellow lines. It lives, at altitudes of 6—8000 ft., on a Bignonia with thick clusters of yellow blossoms.
- aper*. **E. aper** Wkr. (93 d) is larger than *dauidianus*, the orange abdominal spots are much larger and the antemedian lines form an acute angle. The nomenclatural type exhibits indistinct ventral dots on the 3rd to 5th segments, the postmedian band of the forewing composed of 3 lines is distinctly marked. Venezuela and Colombia.
- guttiventris*. **E. guttiventris** R. & J. shows distinct whitish ventral spots and a light basal ventral spot, the discal band of the forewing and the light veins are less distinct. The black spots of the forewing are smaller, the grey discal line is more dentate; fringe more intensely speckled blackish-brown. Genitally different. Colombia and Bolivia, occurring beside *aper*.

7. Genus: **Dolba** Wkr.

Very closely allied with *Protoparce*, separated by very long scales on the head, which hang over the eyes as long cilia. Pulvillus and paronychium present. Only 2 species.

Type: *D. hylaeus* Dru.

- hylaeus*. **D. hylaeus** Dru. (= *prini* Abb. & Sm.) (90 e) resembles a small *P. rustica*; forewing whitish-grey, scaled olive brown, the most densely so in the centre of the wing, the antemedian and marginal areas remaining purer white; a white discal spot at the cell-end. The race from North-Eastern North America shows a distinct contrast between the white and dark areas of the wings, and beneath there is a double, very distinct postmedian line bordered with white distally. — *floridensis* Clark (90 d), from Florida, is more monotonously coloured, not so contrastingly dark and white, more grey; the distinct postmedian line of the forewing beneath has more or less disappeared here. Larva with 6 distinct oblique stripes which are bordered with red anteriorly, with pink posteriorly, the stripe on the 5th segment is indistinct. It lives on Pinos, Ilex, Comptonia, Asimia.
- clarki*. **D. clarki** Carlos Hoffm. (90 a) is likewise closely allied. Body blackish-brown, intermixed with whitish hairs which predominate on the thorax, ventral side whitish with a yellowish tint, abdomen with a darker dorsal line and subdorsal lines. Forewing brownish black with a violet tint and mixed with white; anterior transverse band indistinctly double, posterior band prominent and distinctly double, bordered by a whitish transverse band outside; black longitudinal streaks between 2 and 4; stigma yellowish white. Hindwing brownish black, basally lighter, with 2 slightly darker transverse bands, the space between them lighter, the exterior one terminates anally with a blackish spot. Fringe blackish-brown speckled with white. According to 1 ♀ from Malinche near Puebla (Mexico), at an altitude of 2250 m, taken in August.

D. schausi *Clark* (91 a) is very closely allied to *clarki*; the white abdominal spots much smaller; the *schausi*. distinct black markings on the forewing of *hylaesus* are brown, the white areas on the wings are strewn with brown and the ground-colour is therefore more monotonous, the marking more blurred; postmedian line indistinct and less sharply dentate. Forewing marked lighter brown. Colombia (Cauca Valley).

8. Genus: **Dolbogene** *R. & J.*

Distinguished from *Dolba* by the short, long-spined first protarsal segment and shorter spurs. Only 2 species:

D. hartwegi *Blbr.* (= *hylaesus* *Wkr.* part.) (91 a). A small brownish grey species distinguished by the *hartwegi*. very strong black vein-streaks on 2 and 3 and subapically; transverse markings as in the allies; postdiscal spot mostly somewhat darkened. Hindwing greyish-brown, lighter at the base. Mexico to Honduras.

D. manni *Clark* (91 d). Forewing smoky brown, clouded lighter, more monotonous than *hartwegi*, *manni*. smaller and with narrower wings, with a white spot at the cell-end; inner margin darkened in the basal half, the transverse markings more diffuse. Hindwing smoky brown, the light transverse band narrower than in *hartwegi* and whitish analwards. Mexico, Guerrero.

9. Genus: **Isogramma** *R. & J.*

Closely allied to *Ceratomia* and *Chlaenogramma*, from which it is separated by the spined anterior tibiae and the apex of the middle tibia; the long terminal spur of the posterior tibia is shorter than the first tarsal joint; pulvillus present. Only 1 species:

I. hageni *Grt.* (93 e) is externally similar to *C. undulosa*, but it is separated by the structural differences *hageni*. and the yellowish-green tint of the colouring. Texas.

10. Genus: **Ceratomia** *Harr.*

Proboscis, palpi and eyes relatively small. Tibiae not armed; anterior tibiae short, the first protarsal joint with 3 or 4 long, thick thorns outside; middle tarsi without bristles. Pulvillus absent; paronychium with 1 lobe on each side. 3 species from North America.

C. amyntor *Hbn.* (= *quadricornis* *Harr.*, *ulmi* *Bsdv.*) (93 e). A large strong species; forewing more *amyntor*. or less strewn with brown on the whitish ground, the head, collar and the costal-marginal half of the forewing remaining lightest; lower half of median area deep dark brown; anterior transverse line only visible as pointed dents in the costal-marginal part, posterior line 3 or 4 fold, feebly dentate and filled with light; intense black longitudinal rays in the median area and subterminally towards the apex. Hindwing lighter greyish-brown, darkened towards the margin, with a narrow and a broad brown marginal band. Larva very peculiar owing to 4 horns on the thoracal segments. It lives on elm.

C. undulosa *Wkr.* (= *brontes* *Wkr.*, *repentinus* *Clem.*) (93 e) is of a lighter whitish-grey ground-colour *undulosa*. with distinct blackish-brown transverse lines; especially those in the postmedian area are very sharply dentate; subterminal line bordered with a somewhat darker brownish colour outside, the subapical dentate line is bordered with white towards the costal margin. Hindwing whitish, brownish grey in the disc, with antemedian and median transverse lines, and a broad blackish-brown marginal band. Larva light green with 7 greenish white oblique bands. It lives on ashes and Liguster. Canada to Carolina. — subsp. **polingi** *Clark* is of a much *polingi*. darker grey total colouring without any yellowish admixture, the stigma is smaller and less prominent, with more intense transverse lines and apical line, submarginal line indistinct; the white colour disappears on the fringe of the hindwing. Texas. — **borealis** *Clark* is the Canadian subspecies from Manitoba, the colouring is *borealis*. intermediate between the two others, with less distinct markings, the stigma often very small, hindwing monotonously dark grey above, with indistinct transverse bands.

C. catalpae *Bsdv.* (94 a) has somewhat narrower wings than the preceding species, of a more brownish *catalpae*. total colouring, the transverse lines much less distinct, particularly the antemedian ones; the postmedian ones are much less curved and more extinct, the black longitudinal rays in the discal area are more distinct and longer. The transverse lines on the brownish hindwing are almost extinct, the marginal band very dark as far as the margin. Larva on Catalpa and occasionally injurious by its immense numbers. It is light green, blackened above, with a light green interrupted subdorsal stripe; head and horn black. New Jersey and Pennsylvania to Florida.

11. Genus: **Isoparce** *R. & J.*

Distinguished by the very short and feeble proboscis, the short palpi being roughly haired. Tibiae spineless, the short first protarsal segment with several thick thorns outside, spurs very long. Pulvillus absent, paronychium without lobes. 6 and 7 of hindwing on a long stalk. Only 1 species:

cupressi. **I. cupressi** Bsd. (94 a). A monotonously brownish-grey small species, easily discernible by an almost longitudinally directed double line between veins 2 and 4 of the forewing. Georgia and Florida, apparently very rare. Larva unknown.

12. Genus: **Nannoparce** R. & J.

Proboscis longer than body; legs as in *Ceratonia*, but the middle tarsi exhibit a comb of bristles. Only 1 species:

pocyi. **N. pocyi** Grt. & R. (93 c) is likewise a smaller species, thorax bluish ash-grey, head and abdomen more brownish, like the forewing which exhibits a whitish dentate postmedian transverse band bordered with a darker brown towards the base especially in the cell; transverse markings very indistinct in the antemedian area, more distinct only in the costal-marginal area; black longitudinal streaks as well as the oblique streak parting the apex fine; some more black indistinct dentate blotches subterminally. Hindwing brown, lighter whitish at the inner margin. Cuba and Jamaica. — *haterius* Drc. is a rare form found in Yucatan, the forewings more intensely darkened blackish-brown, especially in the disc and at the costal margin.

13. Genus: **Dictyosoma** R. & J.

Proboscis shorter than body, palpi slender, short, hairy; the small eyes not ciliated; antennae strong. First protarsal segment with 3 long thorns, middle tarsi without the comb of bristles, the spurs of the middle and posterior tibiae very short. Pulvillus absent, paronychium without lobes. Only 1 isolated species:

elsa. **D. elsa** Stkr. (93 c) is an apparently extremely rare and quite different species, slightly recalling a small pale *ligustri*. Forewing reddish whitish-grey, quite light in the costal-marginal area, with 4 blackish-brown very oblique transverse markings in the inner-marginal third, the most distal one of which terminates into a fine apical streak. Hindwing whitish with a black base and 2 transverse bands; the light abdomen with black segments and with dorsal and subdorsal stripes. Larva green, granulated, with 6 red-brown oblique lateral stripes. Arizona.

14. Genus: **Neogene** R. & J.

Like the preceding genus, but the eyes are overhung by cilia. Legs similar as in *Dictyosoma*, but the middle tarsi exhibit 2 or 3 long bristles instead of the comb. Paronychium with 1 long lobe.

reevi. **N. reevi** Drc. (= *baruta* Berg, *cossoides* Rothsch.) (94 a) shows hardly any markings, the body and forewing are brownish grey with a yellowish ochreous tint, with a subterminal brown band bordered with whitish outside; tegulae with some grey hairs. Abdomen yellowish-white laterally, with large black spots. Forewing brownish, hindwing yellowish-white with a black marginal band. Argentina; Paraguay and Paraná.

curitiba. **N. curitiba** Jones resembles *reevi*, but it has an entirely blackish-brown thorax, and the forewing is suffused with black, a white discal spot is present and the fringe is spotted white. Abdomen deep blackish-brown above, intermixed with single ochreous hairs, laterally ochreous, spotted black, the last segments darker blackish-brown. Especially the basal and marginal areas of the forewing are much darker. Expanse of wings: ♂ 66, ♀ 75 mm. Curitiba, Paraná.

dynaeus. **N. dynaeus** Hbn. (94 a) is a small species; body blackish-brown, head, borders of neck and tegulae reddish-white, abdomen with white lateral spots. Forewing greyish-white, brown in the whole basal half and at the margin especially analwards; discal spot and a broad subapical oblique band white; subterminal white stripes between the veins 4 and 7. Hindwing greyish-white with faded brownish postmedian and marginal bands. A rare species from Bahia and Pernambuco. — *corumbensis* Clark is much more brown instead of grey, abdomen brown, not black, head and border of tegulae yellowish instead of white. The white markings on the forewing are almost quite absent. Hindwing monotonously brown above and beneath. From Matto Grosso. The larva which has much to suffer from parasites (Hymenoptera) was found by the Rev. Moss near Pernambuco on a Verbenacea; he describes it to be whitish-green with a red dorsal line terminating into the fine black horn; round white black-ringed subdorsal spots, and black spots of various sizes increasing in the growing insect.

steinbachi. **N. steinbachi** Clark is near to *dynaeus corumbensis*. Antennae and palpi dark brown, frons chalky white, occiput with a black transverse streak. Thorax dark brown, tegulae grey, abdomen grey above, with white and black lateral spots. Forewing grey with a white, S-shaped postmedian band of 2 mm width, pointedly extended between the veins; 2 angular black antemedian and median lines arise at the inner margin and extend to the cell, besides two lines behind the centre and between veins 2 and 3 near the cell a short black

longitudinal streak; a light dot at the cell-apex and a black dot above it. Hindwing plainly grey with a somewhat darker marginal band. Bolivia.

N. albescens Clark. Frons grey, thorax dark grey with lighter tegulae. Abdomen light grey above, *albescens*. laterally white with large black spots. Forewing white, a fine dark line proceeds at the inner margin, 5 mm from the base, obliquely to the cell, where it is sharply bent round and returns to the base of the costal margin; a very faint parallel line in front of it; the dark marginal area is narrower and lighter than in *steinbachi*, only a white dot at the cell-apex. Hindwing monotonously light grey, with dark veins and a distinct dark marginal band. From Argentina (La Rioja).

15. Genus: **Atreides** Holl.

Eyes edged with cilia, proboscis long. Anterior and middle tibiae spined; posterior tibia as long as the first tarsal joint, with very long spurs, the longer spur reaching to the end of the first tarsal joint. Only 1 species:

A. plebeja F. (94 b). Body and forewing brownish-grey with distinct black dentate lines and a very *plebeja*. small lighter, dark-edged discal spot; small black sagittate spots between the black veins of the marginal area; fringe speckled light and dark. Hindwing almost entirely black, lighter whitish grey only in the costal-marginal portion and in 2 small diffuse spots near the anal angle. Larva green, lighter or also reddish on the dorsum, with 7 yellow lateral oblique bands bordered with black or red above; skin intensely granulated, horn granulated black. It lives on Teeoma. Eastern United States.

16. Genus: **Sphinx** L.

A large number of partly very closely allied species are combined under this name to-day, part of which formed the genus *Hyloicus* Hbn. Eyes ciliated, anterior tibiae spined. Pulvillus absent. The spines of the middle and hind tibiae vary much in number and length in the different species, and they may even be absent. Abdomen almost invariably with black and white lateral spots, never yellow.

S. arthuri Rothschild. (94 b) is easily recognizable by the peculiar reddish olive green colouring of the *arthuri*. anterior body and forewings; with hardly any markings. Metanotum with 2 golden yellow spots. A single ♂ from La Paz, Bolivia.

S. maura Burm. (94 b) is quite similar to *arthuri*, and ROTHSCHILD suspects it to be the ♀ of it, since *maura*. only ♀♀ are known of *maura*, but the colouring is blackish-grey, whilst the shape and marking of the wings is the same in both species; abdomen not so white as in *arthuri*. Argentina and Espiritu Santo.

S. aurigutta R. & J. (94 e) is similar to *lugens*, but larger, and the anterior body slightly brownish; *aurigutta*. 2 golden yellow spots on the metathorax; markings of forewing not very distinct; some rusty-reddish scales before the anterior transverse line below the cell; the white cell-end spot is double, the greyish-white irregular submarginal line extends almost parallel to the margin. Bands of hindwing slightly brownish. Peru and Bolivia.

S. justiciae Wkr. (= *anteros* Mén.) seems to be an extraordinarily rare species the exterior of which *justiciae*. entirely resembles that of the following *merops*; it differs from it, however, in the orange border of the abdominal margins near the dorsal line and in the genital apparatus. Larva green with 7 reddish violet, posteriorly white-edged oblique bands, each of which is continued to the next segment by yellow colour; thoracic rings granulated. It lives on Justicia (Acanthaceae). Rio de Janeiro to Buenos Aires.

S. merops Bsdv. (= *lugens* Bsdv., *justiciae* Drc.) (94 e) is at once discernible from *justiciae* by the absence *merops*. of the two orange subdorsal spots on the abdomen, but it exhibits a rusty yellow tinge above on each side of the median line, and the forewing also shows red-brown places; the submarginal line being thickly black in the lower two thirds is bordered with yellowish-white distally. Mexico to Ecuador. Although the species is very common and widely distributed, yet the larva is not known.

S. tricolor Clark belongs to the *merops-justiciae* group, but it has shorter and obtuser wings. Head *tricolor*. and thorax grey, tegulae white, strewn with brown. Abdomen above with a yellow median stripe interrupted by slate-blue segmental indentations which are more conspicuous laterally, with black between them; ventral side yellow, strewn with brown. The costal and distal margins of the forewing form a right angle at the apex, the inner angle being quite round. Forewing grey, marked with black and white, lighter than in *merops* and *justiciae*, with a subbasal brick-red longitudinal blotch of 7 mm length; a double white stigma bordered with black; instead of the black submarginal band there are 3 black, distally white-edged lines here. Hindwing with a slate-blue basal area and median band. Dominica, from an altitude of 900 m, the only West Indian representative of the genus discovered hitherto.

- lugens*. **S. lugens** Wkr. (= andromedae Bsdv.) (94 c) is distinguished from the similar species by the abdomen beneath, on the white ground of which only the first spot is large and black, the others being very small or extinct. Forewing blackish-grey, mostly with a slight brownish hue in the ♂, with almost the same marking as in all the allies. Mexico to Honduras.
- geminus*. **S. geminus** R. & J. is so very similar to *lugens* that it can only be separated by the different genital apparatus and by the ventral side invariably bearing 5 large, well developed black spots. The harp is distally rounded, whilst in *lugens* it is extended hook-like at the upper angle. Likewise found from Mexico to Honduras.
- biolleyi*. **S. biolleyi** Schs. is very near to *geminus*, but of a more brown total colouring, intermixed with light reddish yellow; a pinkish-whitish antemedian spot below the cell is parted by a black line; a round blackish-brown spot in the cell is crossed by a black longitudinal streak, and a white dot is at the cross-vein. The antemedian white line of the hindwing is thinner, the fringe more intensely speckled black. 1 ♀ from Costa Rica.
- eremitus*. **S. eremitus** Hbn. (= sordida Harr.) (94 d) is very similar to *lugens* and *geminus*, but structurally separated by the spined middle tibiae — being spineless in the two species mentioned — and by the shorter first protarsal joint. Brownish, marked like the preceding species; the black longitudinal streaks are distinct and thick. The peculiar larva is distinguished by a three-edged projection on the 3rd thoracic segment and a velvety black dorsal spot on the two following ones. It lives on Labiatae (Mentha, Salvia, Monarda). Canada
- mccrearyi*. to Georgia, to the west as far as Missouri. — **mccrearyi** Clark shows a darker brown thorax and abdomen above, and the ground-colour of the forewings is much darker, too; the upper one of the two small white discal spots of *eremitus* is black here or absent altogether. Bands of hindwing blacker. Manitoba.
- pseudo-stigmatica*. **S. pseudostigmatica** Gehlen (94 d) is the most closely allied to *eremitus* and just as large, but of more slender wing-contours. Forewing darker than in *eremitus*, greyish-brown, without any yellowish tint; all the linear markings finer; the white anal dentate line is absent; a light spot in the centre of the cell, the white stigma scarcely recognizable; fringe brown. Hindwing much less black, the white median band narrower, the black marginal band distally dusted with light grey. Abdomen dark grey; palpi with much denser and longer hair. Mexico.
- eremitoides*. **S. eremitoides** Stkr. (= lugens Grt.). Exterior very similar to that of *separatus* and *lugens*, but lighter, more silvery grey, and smaller than these two, with smaller, more triangular black abdominal spots, the collar lacks the yellow spots of *separatus*, the black stripe on the tegulae is narrower, the basal and central costal-marginal areas are whiter, the black apical streak is thinner. The basal white band of the hindwing is greyer, the black distal margin narrower. Middle tibiae spineless. Southern States of North America. Larva, according to STRECKER, light green with 7 white oblique lateral stripes and a black horn. It lives on Salvia in two generations, in June and October.
- separatus*. **S. separatus** Neum. (= andromedae Bsdv., lugens Sm.) (94 d) is likewise very similar to the preceding species, larger, of a purer grey, irregularly marked and easily recognizable by 2 large ochreous spots on the collar; the area between 2 and 4 on the forewing as far as the submarginal line is darkened grey. Larva unknown.
- metacna*. Colorado, New Mexico, Mexico. — **metacna** R. & J. shows a much darker grey ground-colour, the black marking is therefore less contrasting and the insect also blacker beneath. Mexico (Hidalgo and Cuernavaca).
- istar*. **S. istar** R. & J. (= lugens Wkr., sordida v. A. Clem., leucophaeata Btlr., andromedae Schs.) (94 e) is very similar to *separatus*, still larger, at once discernible by the absence of the two ochreous spots on the collar. Disc of forewing more brownish than in *separatus*, the black longitudinal streak in the distal half of the cell is absent; the antemedian line consists in the inner-marginal half only of two though very thick lines, in *separatus* of 3 finer lines. Distal band of hindwing narrower. Mexico.
- praelongus*. **S. praelongus** R. & J. is still larger with more elongated wings than *istar*, otherwise very much like it, of a purer greyish white, cell with a black apical streak, a white blotch at the double antemedian line. It may be only a southern form of *istar* from Spanish Honduras.
- lanceolata*. **S. lanceolata** Bsdv. (= ? leucophaeata Clem., acuinotialis Bsdv.) (94 e) is one of the largest species. Light grey, somewhat more brownish in the disc, feebly marked, but with a large black basal spot on the forewing, 2 distinct discal black longitudinal streaks and a similar apical streak. Hindwing very extensively black in the costal area. Middle tibiae without spines. Mexico, maybe also Panama.
- chersis*. **S. chersis** Hbn. (= cinera Harris) (94 f) is very similar, smaller, darker and of a duller grey, transverse markings almost obliterated, the black longitudinal streaks finer, the black basal spot on the forewing absent. The ground-colour is decidedly loamy in the nomenclatural form, with brown fringe on the forewing. Canada
- oreodaphne*. to Georgia, to the west as far as Mississippi. — **oreodaphne** Edw. (= chersis Stkr.), from California and Oregon, is a smaller form, the black discal band of the forewing is narrower anteriorly, the median spots on the under

surface of the abdomen are smaller. — **pallescens** *R. & J.*, from Arizona and Colorado, forms a transition to the *pallescens*. following subspecies: as large as *chersis*, whitish-grey as *mexicanus* and with the same white-spotted fringe. — **mexicanus** *R. & J.* is darker in general, although the ground is a purer whitish-grey, without the loamy shine. *mexicanus*. The fine markings are more distinct, fringe spotted white; the black discal band of the hindwing broad. Mexico.

S. adumbrata *Dyar* (94 f) is very similar to *chersis*, smaller, abdomen with 5 pale sulphureous white *adumbrata*. spots laterally, with a fine black dorsal line above; besides the usual black longitudinal streaks on the forewing there are yet double fine postcellular streaks, 1 long fine one in the cell, and a fine submedian streak. Mexico (Zacualpan).

S. vashti *Stkr.* (= *vancouverensis auct.*, *drupiferarum Holl.*) resembles the preceding species in the *vashti*. scheme of markings, but distinctly differs in the almost white collar and tegulae, the latter intensely edged with black inwards. The whole basal costal-marginal portion of the forewing is greyish-white like the terminal area, centre of thorax grey. This is the spring-form from hibernated pupae. — **albescens** *Tepp.* (95 a) is the summer *albescens*. form with a blackened thorax. California, to the west as far as the eastern slopes of the Rocky Mountains. — **gerhardi** *B. & Benj.* is a more intensely strewn form, without any brownish tint, the black subterminal line *gerhardi*. between 6 and 2 is thicker black; thorax somewhat more coarsely clothed. South Nevada. The green larva with white oblique stripes edged anteriorly with black, and with a black horn lives on *Symphoricarpos racemosus*. McDUNNOUGH most meritoriously cleared up the complicated synonymy by examining the types, the type of *vancouverensis* originates from California and is synonymous to *perelegans Edw.*

S. mordecai *McDunn.* (= *albescens R. & J.*, nec *Tepp.*) (94 f) is extremely similar to *vashti*, but much *mordecai*. darker, and with a blackened mesothorax like *albescens*; the species is smaller on the whole than *vashti* and is easily discernible from it by the black subterminal line of the forewing forming an acute angle between veins 2 and 3 and then extending towards the anal angle, almost reaching the inner margin, whereas in *vashti* it vanishes far before this without a flaw; moreover it mostly lacks the interior line accompanying it, or it is very indistinct at least. Vancouver; British Columbia.

S. libocedrus *Edw.* (95 a) resembles *chersis* and is smaller than *vashti*; tegulae finely edged with brown *libocedrus*. inside. The yellowish or white lateral spots on the abdomen are bordered with black all round; the interior angle of the forewing is less rounded than in the allies. The nomenclatural type shows more purely white lateral spots on the abdomen. Arizona. — **insolita** *Lintn.* (= *libocedrus Smith*), from Texas, shows yellowish lateral spots. *insolita*. The larva is unknown.

S. perelegans *Edw.* (= *vancouverensis Edw.*) is very similar though larger than the preceding species; *perelegans*. uniformly silvery grey, recognizable by the fine white streak on vein 6 being prolonged into the cell; the black submarginal line is indistinct. Mesothorax black. California, British Columbia to the Rocky Mountains. — **asellus** *R. & J.* is a much lighter form with a grey mesothorax and a broader white submarginal band. Oregon, *asellus*. Colorado, Arizona. Larva unknown.

S. canadensis *Bsdv.* (= *plota Stkr.*) differs from the preceding species in the more distinct brownish *canadensis*. loamy ground-colour, and from *chersis* especially in a fine dark line in the centre of the tegulae; mesothorax loamy grey. Abdomen above with a very strong dorsal line. An apparently rare species from Canada, New Foundland, New England, Ohio. Early stages unknown.

S. francki *Neumoeg.* (95 b) we can figure from a specimen in the Berlin Museum. ROTHSCHILD and JOR- *francki*. DAN presume it to be a hybrid between *chersis* and *kalmiae*. Kansas.

S. kalmiae *Abb. & Sm.* (95 b) is still more brownish than *canadensis*, much less strewn, and with its *kalmiae*. darkened inner-marginal portion of the forewing it resembles the palaearctic *ligustri*; discal longitudinal streaks thick. Larva on lilac, privet, *Kalmia*, *Chionanthus*, green with distinctly marked black oblique bands and a black-granulated horn. Canada to Georgia, to the west as far as the Mississippi.

S. gordius *Cr.* (= *eremitus Grt.*, *poecila Stph.*) (95 b) is smaller and more robust than *kalmiae*, forewing *gordius*. more intensely strewn with brown, the inner-marginal area not so contrastingly darkened, more irregularly marked. The discal band on the hindwing above and beneath as well as the central spots on the ventral side very distinct. — **oslari** *R. & J.* is a larger and lighter form, the disc of the forewing less shaded with blackish- *oslari*. brown, the discal band on the hindwing beneath less distinct, the spots on the abdomen beneath very small. Colorado. — **borealis** *Clark* is a darker and purer grey race from Ontario, Manitoba, Quebec, Maine. Larva of a *borealis*. bright green, head striped yellow and brown, the white oblique bands bordered with red anteriorly, the horn only laterally black, green above and below. On apple, ash, rose, *Myrica*.

S. luscitiosa *Clem.* (95 b) is easily recognizable, forewing similar to those of the preceding species, but *luscitiosa*. all the margins darker than the brightened disc. Hindwing yellow with a black marginal band, median band

obsolete. Larva with white oblique bands which are bordered with pinkish lilac anteriorly, strewn with small black ring-dots; horn black laterally. On *Salix*, *Populus*, *Betula*. — **bombax** *B. & Benj.* is a western race from *Utah*, both the wings much lighter, the black longitudinal streaks only of half the size. — **una** *Skinner* was established according to 1 aberrative ♀, bred in Brooklyn, darkened on all the wings without the yellowish-reddish colour and therefore looking like *eremitus*.

drupiferarum. **S. drupiferarum** *Abb. & Sm.* (95 c) is exactly like the palaearctic *ligustri*. Thorax blackish-brown, tegulae light inside, edged with pinkish-white like the basal costal-marginal part of the forewing; submarginal area also light. Hindwing with a broad median band and a whitish margin before the dark marginal band. The nomenclatural type flies from Canada to Georgia, to the west as far as the Mississippi, and is very common. — **utahensis** *Edw.* (= *vancouverensis* *Holl.*) is the western form which is much whiter and occurs in the western States from Colorado to Utah, California and Oregon. Larva with red oblique stripes bordered with white posteriorly; on *Prunus*, *Pirus*, *Syringa* etc.

dolli. **S. dolli** *Neumöcg.* is a much smaller species, but it resembles the preceding species in the colour and scheme of markings, but the white costal-marginal part of the forewing is extended to the apex, distinctly separated from the greyish-brownish lower half by the black longitudinal streaks. Hindwing greyish-brown without the black discal and marginal bands. Arizona. — **coloradus** *Sm.* (95 c) is somewhat darker and shows a black submarginal line between the veins 2 and 5, which is absent in the nomenclatural type. Colorado; Utah. *australis*. — **australis** *Clark* is still darker, head and mesothorax dark grey, the dark brown tegulae without the light border; hindwing also darker. Early stages unknown.

sequoiae. **S. sequoiae** *Bsd.* (= *coniferarum* *Wkr.*) (95 c) differs from *dolli* in the costal part of the forewing not being lighter; antennae shorter than in *dolli*; ground-colour more monotonous, more brownish; only the black submarginal stripe in the anal-marginal part is bordered with whitish outside. Hindwing unicoloured brownish-grey. — **engelhardti** *Clark* (95 d) was originally described as a form of *dolli*. Thorax dark grey like forewing and not brownish, markings finer and less distinct. From Utah. Early stages not described.

17. Genus: **Lapara** *Wkr.*

Imago scarcely different from *Sphinx*, except the shorter proboscis and smaller palpi; larva quite different, without a horn and with longitudinal stripes, a triangular head, on conifers. Pupa without a free case of the proboscis.

Type: *bombycoides* *Wkr.*

coniferarum. **L. coniferarum** *Abb. & Sm.* (= *cana* *Martyn*) (95 c). Greyish-brown, somewhat lighter in the anal portion of the forewing, the markings of variable distinctness, postmedian fragments of two transverse lines being most distinct; the discal longitudinal streaks may also be present or absent. Hindwing unicoloured light greyish-brown. Canada to Florida, to the west as far as the Mississippi. Larva green with 3 white longitudinal stripes, often speckled with oblong lighter or darker grey spots. It lives on *Pinus*, especially *P. palustris*. — **pineum** *Lintn.* is probably no distinct species, but only a monotonous extreme aberration, all the markings, transverse lines and discal longitudinal streaks being obsolete. Only 2 specimens known from the State of New York.

bombycoides. **L. bombycoides** *Wkr.* (= *coniferarum* *Harris*, *harrisi* *Clem.*) (95 d) is smaller than the preceding species, likewise most variable, darker brown on the forewing, anterior transverse lines more distinct, the posterior ones more strongly dentate. Canada to Florida, to the west likewise to the Mississippi. The larva differs from that of *coniferarum* in the red face, it also lives on *Pinus*, especially *P. strobus*.

halicarniae. **L. halicarniae** *Stkr.* (95 d) is a rare species, much larger than *coniferarum*, all the markings nearly extinct, so that often only 2 black discal longitudinal streaks are present beside a fine notched posterior transverse line. The type is a pathological specimen with shorter and broader wings. Florida.

Subfamily: **Ambulicinae**.

18. Genus: **Protambulyx** *R. & J.*

Proboscis extending almost to the centre of the abdomen; palpi and frons situate almost on a level; a transverse comb of hair between the antennae. Dorsal segments of abdomen distally spined; tibiae spineless; pulvillus present. Distal margin of forewing cut out below the apex. Abdomen with oblique lateral stripes. Part of the species are difficult to distinguish.

Type: *P. strigilis* *L.*

P. eurycles H.-S. (96 a). Very similar to *strigilis*, but easily discernible by much lighter yellow hindwings and under surface of wings and body; forewing much more produced on vein 7, a subbasal large olive-black spot. The brown marginal band of the forewing beneath is broader; the antemarginal band on the hindwing above is concave between 8 and 4 and strongly angled on 4. Colombia to Rio de Janeiro. Larva green, granulated yellow, the head triangularly pointed, with a yellowish lateral stripe on the 3 first segments, feebly yellowish oblique stripes anteriorly bordered with a darker green on the other segments, and 4 large orange red lateral spots on the 5th to 8th segments; horn almost straight, very long; on Anacardiaceae. *eurycles*.

P. fasciatus Gehlen (96 a) is allied to *eurycles*, but the head and prothorax are darker. Forewing with more distinct antemedian and postmedian transverse bands and a lighter median area between them, interrupted dark between veins 2 and 3; subbasal spot less broad. The yellow basal area is more extensive, because the very strong 1st discal line is removed more distally; the discal lines are partly confluent. Very different from *eurycles* beneath, the dark marginal half distinctly contrasting with the light basal half. 1 ♂ from Sa. Catharina. *fasciatus*.

P. xanthus R. & J. resembles *eurycles*, but the posterior subbasal spot is narrower and more obliquely arranged. Hindwing very pale chromatic yellow, the transverse lines as in *euryalus*, the first line broader and nearer to the cell, the marginal band narrower. Length of forewing: 60 mm. Costa Rica. *xanthus*.

P. euryalus R. & J. (96 b) is very similar to *eurycles*, the 2nd abdominal segment less grey above; forewing also less grey, more reddish-yellow, with larger olive green costal-marginal spots, the two spots at the cell-end and behind it are contiguous; marginal band blackish-brown, almost equably broad, apically pointed, bordered by a blackish line, proximally to it an olive green, sharply defined band which is much less sharply defined in *eurycles* and much broader between veins 5 and 6. Apex of hindwing obtuser, anal angle less produced, the black postdiscal band more uniformly curved. Venezuela; Peru. *euryalus*.

P. ockendeni R. & J. resembles *euryalus*, forewing more monotonous above, not so variegated, more violettish grey in the basal half, the olive marginal band much narrower between veins 4 and 6; the 3rd discal line on the hindwing is finer, more uniform, less dentate. South-Eastern Peru, 6000 ft. *ockendeni*.

P. sulphurea Rothsch. Wings shaped as in *eurycles*, but somewhat narrower; much lighter, hindwing lemon-coloured; the forewing lacks the large costal spots and the subbasal inner-marginal spots; discal lines also dentate on vein 5; feebly tinged with reddish pink in the basal half; the double marginal band is much narrower between 6 and 4 than in *eurycles*. The 2nd and 3rd lines on the hindwing are fine, the 3rd curved as in *euryalus*. Venezuela. *sulphurea*.

P. astygonus Bsd. (96 a). Very similar to *goeldii*; forewing above without a stigma; the first line on the hindwing is S-shaped, much less curved than in *goeldii*, and nearer to the base, the 2nd is very fine or absent altogether, the 3rd regularly dentate. Distal margin of hindwing more convex. The marginal band on the forewing beneath is very broad, crescentiform. Brazil. *astygonus*.

P. goeldii R. & J. (96 b). Body above yellow-reddish grey, with a silky gloss, thorax marked olive green, the oblique lateral stripes of the abdomen yellowish olive green, the 8th segment olive green above. Forewing like body, marked olive green, hindwing maize-coloured, with a straighter distal margin. Forewing with a large discal spot. Peru. — **andicus** Gehlen has broader forewings of a darker ground-colour, with a still larger stigma, hindwing deeper orange with a broader red-brown submarginal band. West Colombia. *goeldii*. *andicus*.

P. strigilis L. (96 b) is a very widely distributed and common species. Forewing mostly with a rather uniform silky gloss, olive brownish, sometimes more yellow, sometimes more brown, finely marked, with a small discal dot. Hindwing coppery orange, with 3 fine discal lines, the 1st and 2nd united at the inner margin, striated in tan-colour beneath, sometimes also above so densely that the hindwing turns rusty brown and the lines are almost covered by it; this is: — ab. **rubripennis** Btlr. The larva is very variable, green, with or without yellow granulation, or claret-coloured, the former with light yellow oblique stripes, the latter with darker red ones, often with dark spots before them. It lives on Cajú (Anacardiaceae). Mexico to South Brazil, Cuba; West Indies. *strigilis*. *rubripennis*.

P. carteri R. & J. resembles *strigilis*, but it is distinctly separated by the absence of the submarginal line on the forewing, and the oblique lateral lines on the abdomen are also absent or very indistinct. Forewing broader, the indentation below the apex much shallower; the disc only shows one transverse line starting at the olive costal-marginal spot of the cell; only the extreme margin is purple brown. Hindwing as in ab. *rubripennis* with traces of 2 discal lines, the median line being absent; the brown marginal band is feebly developed. Probably only an insular race of the preceding species from the Bahamas and Florida. *carteri*.

19. Genus: **Amplypterus** Hbn.

Separated from the preceding genus by somewhat longer palpi which form an obtuse angle with the frons; antennae longer. The lobate angle on the forewing projects farther below the apex. Otherwise almost the same.

Type: *A. gannascus* Stoll.

gannascus. **A. gannascus** Stoll (= *ganascus* Hbn., *rostralis* Bsdv., *daphne* Bsd., *sexoculata* Btlr.) (96 c) is an extremely common and variable insect regarding the ground-colour and the extent of the dark marking. Light yellowish, reddish or violettish-brown, olive brown or chocolate brown spots; the basal oblique band may be broad or narrow, reaching the costal margin or not; mostly a lighter blotch behind the cell. The 3 black bands of the hindwing are often very broad and partly confluent. The extremest forms are: — **mollis** Gehlen (96 c). Forewing loamy yellow, with no marking except the very narrow blackish-brown subbasal band only extending to the cell, a small subapical spot and a small spot above the inner margin near the anal angle; the two exterior bands on the hindwing are confluent. From Sa. Catharina. — **magicus** Gehlen (96 c) is the reverse of it, extremely large and very profusely marked, of a dark brown ground-colour. Hindwing red basally, black distally with 3 rows of yellowish-white spots. Colombia. Other forms named are: — **rubra** Closs, a feebly marked form, the ground-colour turning more red-brown. — **grisescens** Closs. Body and forewing silvery grey, from Icononzo (Colombia). — **fulvescens** Closs, body and forewing reddish-yellow, from Orizaba (Mexico). — **acostalis** Closs, the dark subbasal band not extending to the costal margin, likewise from Mexico. — **interrupta** Closs. The black submarginal band of the hindwing is interrupted here between the veins and broken up into rhombic spots; Mexico. — **connexa** Closs. The black bands of the hindwing are very strong and confluent, so that the hindwing sometimes turns quite black. São Paulo. — **cubanus** R. & J., from Cuba, has shorter and broader forewings. — **jamaicensis** R. & J. is a large race with broad wings, the greyish cinnamon forewing with a broader subbasal band. Bands of hindwing narrow and situate more distally. The black spots beneath are almost extinct. Jamaica.

dentoni. **A. dentoni** Clark (96 c) has narrower wings than *gannascus* and of a lighter grey colour, varying to whitish-grey; apex of forewing more produced, distal margin more convex, the subanal spot of the forewing is greatly reduced, the transverse linear marking more distinctly prominent; marginal area darkened brownish-grey, the dark spots more dark chestnut-brown, not olive. The black bands of the hindwing are broad. Peru (Chanchamayo).

ypsilon. **A. ypsilon** R. & J. (96 e). Body with a brighter red and green marking than in *gannascus*, wings broader; ground-colour variable, from yellowish-brown to deep carmine-brown. Subbasal band much broader and extending to the base especially at the inner margin, subapical spot also much larger, vein 6 brown in its entire length, marginal area extensively brown or olive. Shape of hindwing broader, median band scarcely dentate, the two distal ones confluent except the costal-marginal portion where they comprise a red triangle of the ground-colour; marginal area behind them olive yellowish-brown, somewhat pink only towards the costal margin. Mexico to Ecuador.

palmeri. **A. palmeri** Bsdv. (= *ganascus* Wkr., *marginata* Btlr.) (96 d) chiefly differs from *ypsilon* in the subbasal band being broadly interrupted in the cell, its costal-marginal portion being generally lighter brown, and behind it there is an oblique line extending to the centre of the costal margin. Hindwing with a broad blackish-brown marginal band. Separated beneath by the absence of the large black spots in the basal third of the forewing, by which the two preceding species are distinguished. Most variable. Brazil; Colombia; Peru; Venezuela. Early stages unknown. — ab. **rubicunda** Closs is without discal bands on the hindwing, and the black marginal band is very indistinct; very similar is: — ab. **rubrimargo** Gehlen, where the hindwing only shows the proximal one of the 3 bands, the two distal ones being scarcely traceable, the marginal area with a yellowish tint. Brazil. — ab. **flavellus** Gehlen has a red basal part of the hindwing, and the space between the median band and submarginal band is yellow; the forewing lacks the median spot between veins 2 and 3 and the two small anal spots. 1 ♂ from Novo Friburgo. — **flavus** Niepelt has an olive yellowish-grey ground-colour of the forewings, and pale yellow hindwings with a slight pink hue, without the black marginal band, with traces of the interior band, without the median band. 1 ♂ from Rio de Janeiro. — subsp. **brasilensis** Clark (96 d) is of a lighter and more yellowish tint than western forms, and the red colour of the hindwing is lighter, and the dark marking on the forewing is duller. Rio de Janeiro.

eurysthenes. **A. eurysthenes** Fldr. (= *crethon* Bsd., *schausi* Rothschild.) (96 e) is near to *palmeri*, but easily discernible by the non-interrupted olive green subbasal band of the forewing and the much less oblique antemedian line extending almost parallel to the subbasal band. Hindwing pink with 2 feeble discal lines and a broad blackish-brown marginal band. Espiritu Santo to Colombia.

tigrina. **A. tigrina** Fldr. (97 a). Scheme of markings somewhat like that of *gannascus*, but the hindwings are straw-coloured. Forewing brownish tan-coloured, subbasal band interrupted, the upper portion distally removed, only an oval spot in the cell; vein 6 distinctly blackish-brown. Hindwing with distinct black veins and 3 transverse bands. Venezuela; Colombia; Ecuador; Peru; Bolivia; South Brazil. — **coronata** Gehlen (97 a) is the race from West Colombia, distinguished by more intense whitish-grey dusting; the dark preapical spot assumes the shape of a crown the points of which show towards the base. The triangular subanal spots of the hindwing are enlarged.

sexoculata. **A. sexoculata** Grt. (= *depuiseti* Obth.) (97 a) looks like a very dark *gannascus*, but is structurally different like *tigrina* by the spined anterior and middle tibiae. Forewing deep chocolate brown, quite similarly marked as *gannascus*. Hindwing pinkish-red in the basal half, more yellowish orange distally, veins very thick, distally widened blackish-brown. Venezuela; Colombia; Ecuador; Peru; Bolivia.

A. globifer Dyar. Light olive ochraceous, vertex and a large spot on the tegulae olive brown; forewing *globifer*. with a large pear-shaped olive brown subbasal spot the upper end of which traverses the median vein; feeble double lines behind it; distal line parallel to the margin, brown, vanishing in the irregular shading of the distal third, a curved black line and bluish dusting near the anal angle; a brown subapical shadow. Hindwing dark pink with a broad brown submarginal shadow and 2 median lines. Expanse of wings: 115 mm. Mexico.

A. donysa Drc. (97 b) is one of the most beautiful species, easily recognised by the distinct broad, non-*dony* dentate, very oblique median line of the forewing. ♂ light olive or yellowish-brown in the basal portion, the distal portion mostly of a beautiful olive green; subbasal spot large, oval, two dentate lines in the subterminal area. Hindwing bright carmine with a black postmedian band distally extending into long vein-dents, and a fine antemedian line. The ♀ is more monotonously brown, the distal transverse lines almost obsolete, a light greenish almost reniform spot crosses the transverse line between 2 and 4, the concavity being turned downwards. Mexico to Panama. — subsp. **dariensis** R. & J. exhibits a less sharply defined grey *dariensis*. marginal area on the forewing beneath, and the dark spot before the antennae contrasts less with the occiput. Costa Rica.

20. Genus: **Orecta** R. & J.

Proboscis short and feeble; head small, frons vertically inclined, a comb-shaped transverse tuft between the antennae. Eyes ciliated; palpi similar as in *Amphypterus*. Legs shorter than in that genus. Tibiae spineless, only the anterior tibia with a spine at the end. Pulvillus present. Forewing with a falciform apex, without the subapical indentation of the preceding genera.

Type: *O. lycidas* Bsd.

O. lycidas Bsd. (= *tithonus* Ky.) (97 b). Markings of a most variable development. Lighter or dark-*lycid* er pinkish-brownish, more yellowish in the marginal area; tegulae and the subbasal spot, which is shaped as in the species of the preceding genus, olive brown; some dentate transverse lines are more distinct especially in the marginal area and are intensified analwards. Hindwing darker pinkish-brown, at the anal angle a double spot edged by two blackish lines and clothed with oval scales which very easily fall off, so that it mostly appears transparent. The nomenclatural type is from Brazil (Espírito Santo, Rio de Janeiro, São Paulo, Paraná). — **eos** Burm. (= *lycidus* Burm.) (97 c) is the subspecies from Argentina and Uruguay, with less pro-*eos* duced apex of the forewing and a more convex distal margin; the subbasal band is more oblique, the subapical costal-marginal spot is smaller. Larva long and slender with a triangular head, a very long upcurved horn; green with white subdorsal lines, on *Oreodaphne acutifolia*.

O. fruhstorferi Clark (97 e) is not synonymous with *lycidas*, but separated by its darker colouring *fruh-* and more intense and contrasting marking; subbasal spots more distally situated, a distinctly dark band at *storferi*. the margin; two more distinct transverse bands on the hindwing. Venezuela.

O. acuminata Clark is light yellowish-red on the body and wings, tegulae red-brown; subbasal spot *acuminata*. 2 mm broad, 4 mm long, beginning at the inner margin 3 mm behind the base and ending at the costal margin in a point at the first quarter; a distinct dark brown spot at the cell-apex, 3 smaller dots between this spot and the apex; a sharply defined band at the margin, narrowed above and at the anal angle; a dark longitudinal streak of 4 mm length on the submedian fold near the anal angle. Hindwing unicoloured with dark brown fringe and a dark dot and transverse streak at the anal angle. Length of forewing: 37 mm. 1 ♂ from Tucuman (Argentina).

21. Genus: **Trogolegnum** R. & J.

Proboscis still feebler than in the preceding species, palpi short, coarsely haired; head and eyes small. Tibiae spineless, anterior tibia without an apical spine. Margin of forewing indented below the apex and between 4 and 6; 6 and 7 of hindwing on a rather long stalk. Only 1 species:

T. pseudambulyx Bsd. (97 e) in colouring resembles *A. donysa*, but the subbasal band of the forewing *pseud-* reaches the costal margin; the produced lobe below the apical indentation is broadly rounded. Total colouring *ambulyx*. duller, light reddish greyish-brown, the markings with an olive tint. Hindwing pink, the black longitudinal vein-marking predominates over the feebly marked transverse bands. Hitherto only known from Mexico and apparently extremely rare.

22. Genus: **Smerinthus** Latr.

Proboscis very feeble and short, palpi short in the ♀, longer in the ♂; frenulum stunted, retinaculum quite absent in the ♀. Antennae of ♂ shortly pectinated. Anterior tibia with an apical spine in *cerisyi*, without it in *jamaicensis*.

Type: *S. ocellata* L. (palaearctic).

- cerisyi*. **S. cerisy** Ky. (= *geminatus* Wkr.) superficially resembles the palaearctic *ocellata*; forewing light brownish ash-grey, with a median line sharply angled on 2, a dark brown area behind it in the inner-marginal half, continued eostally as a shadowy stripe obliquely to the eostal margin, 2 feeble and 1 strong undulate line behind it, a triangular dark brown anal spot behind the last line; marginal area darkened. Disc of hindwing pink, anal eyespot light blue, surrounded and centred with black. The nomenclatural type is distinctly marked, the brown postdiscal lunae are more curved than in the other forms: Canada, New England, New York, Rhode Island. — **astarte** Stkr. (= *cerisyi* Sm.) is not always distinctly separable from the type; distal margin of forewing somewhat less dentate, the brown marginal area is narrower, the postdiscal lunae are less curved. Colorado and States to the west of the Mississippi excepting the Pacific coast. — **ophthalmica** Bsd. (= *vancouverensis* Btlr.) (96 c) is generally lighter than *astarte*, ash-grey; a subordinate form: — **pallidulus** Edw. is more cinnamon reddish-grey. South California to Vancouver. — **nigrescens** Clark (97 d), from California (Mission S. José), founded upon 3 couples, is dark olive brown above, the light areas silvery grey; hindwing darker, the pink area reduced, the blue ring very narrow and darkened. — **borealis** Clark is likewise a darkened form, blackened on both wings above and beneath, but the pink area very bright. Manitoba. — **saliceti** Bsd. (*ophthalmica* Bsd.) (96 e) is scarcely different genitally; the blue ring of the hindwing is very extensive and bright. Arizona and Mexico. Larva light green with yellowish-white oblique stripes in the sides, horn blue with a black point; on willows.
- jamaicensis*. **S. jamaicensis** Dru. (= *excaecatus* Lintn., *myops* Btlr. *ocellata* F.) (97 d) is of a very similar exterior, but the anterior tibia is without the apical spine. Antennae much longer pectinated. Smaller on an average, median line of forewing not so pointed, but indistinctly twice angled, postdiscal lines less undulated; colour and marking, as well as development of the eye-spot very variable. The nomenclatural type has only one blue spot in the eye-spot. The normal form: — **geminatus** Say. (97 e) has 2 blue spots. — **tripartitus** Grot. (97 d) has 3 blue separated small spots. New Foundland, Canada to Virginia and Arizona; Iowa. Larva light green, granulated green or white, with light yellow lateral bands, the last being of a deeper yellow; horn blue; on prunus and other trees. — **gamma** Ckll. has pale forewings with a very contrasting dark brown longitudinal band below the stigma and a similar angular antemedian band, so that they together form a horizontal Y-mark; hindwing not suffused with dark behind the ocellus. Colorado. — **flavitincta** Nixon is also light on forewing, but with yellow hindwings which otherwise belong to the form *geminatus*. 1 ♂ from Baltimore. — **clarkii** *clarkii* Franck is a melanotic aberration from Coney Island.

23. Genus : **Calasymbolus** Grt.

Very near to *Smerinthus*, separated by a high comb of scales on the head between the antennae and differently shaped hindwings which project costally in a rounded lobe. Anterior tibia without an apical spine.

Type: *C. astylus* Dru.

- excaecata*. **C. excaecata** Abb. & Sm. (= *pavonina* Geyer) (97 d) exactly resembles the preceding species in its exterior, ground-colour browner, ocellus of hindwing not centred. Distal margin of forewing undulated, fringe white, brown at the ends of the veins. Common from Canada to Florida, to the west as far as the Mississippi.
- borealis*. — **borealis** Clark is a smaller form, much darker, with more contrasting light and dark parts. Cellular stigma smaller. Manitoba. — **pecosensis** Ckll. on the contrary is a much lighter desert-form of the South-Western States. Larva green, darker ventrally, with yellowish lateral oblique stripes, the last widened, often with red dorsolateral and ventrolateral spots. It lives on many trees and shrubs: Prunus, Rosa, Corylus, Carpinus, Betula etc. — hybr. **neopalaearcticus** Stfs., from a copulation of *ocellata* L. ♂ + *excaecata* ♀ is of a very bright red-brown colour with *ocellata*-marking on the forewing. Ocellus of hindwing combined from both the parents, but somewhat variable, in some species more inclined to the one species, in some to the other species. Abdomen with the dorsal line of *excaecata*.
- myops*. **C. myops** Abb. & Sm. (= *rosaearum* Bsd., *cerasi* Bsd., *tiliastris* Bsd., *sorbi* Bsd.) (97 b). Distal margin of forewing not undulated; ground-colour bright red-brown, not so contrasting; postdiscal transverse lines very undulate, shaded between 6 and 7. Hindwing predominantly reddish yellow, ocellus small. — **occidentalis** Clark is the subspecies from Colorado, much lighter than eastern specimens, light yellowish brown, feebly strewn with reddish, the light and dark parts more distinctly contrasting; the blue centre of the ocellus of the hindwing is smaller. — **mcCrearyi** Clark, from Manitoba, on the contrary is a much darker form, but also with brightly contrasting light and dark areas, dark brown, marked purple in the apical area. Larva similar to that of *excaecata*, but more finely granulated. On Prunus and other Rosaecac. Distributed from Canada to Georgia, to the west as far as the Mississippi and Colorado. — hybr. **wormsbacheri** John originates from a cross-breed between *myops* ♂ and *ocellata* ♀; little different from *myops*, but hindwing more pink and the dark thoracal spot indicated. — hybr. **myoastylus** John is the result from a cross-breed of *myops* ♂ with *astylus* ♀; it likewise resembles much the light specimens of *myops* with a more faded marking; the distal margin of the hindwing, however, is not so dark, more light yellow as in *astylus*. Both the sexes were bred.

C. astylus Dru. (= *integerrima* Harris, io Grey) is the rarest of the 3 species. Distal margin of fore-*astylus*. wing not produced at all subapically and on 3, but quite smooth, transverse markings almost extinct, only traceable in the apical part of the costal margin; inner margin very dark. Larva light green with a red lateral stripe and small irregular red dorsolateral spots; it lives on *Vaccinium*, *Rosaceae*, *Andromeda* etc. Canada to New York and Pennsylvania. — hybr. **interfaunus** Neumoeg. ist rather intermediary between *astylus* and *interfaunus*. *Sm. ocellata*; a short apical spine on the anterior tibia is present.

24. Genus: **Pachysphinx** R. & J.

It differs little from *Smerinthus*. Anterior tibia with a strong apical spine; frenulum absent in both sexes. The larvae differ more in the reduced horn, thickened thoracal segments, and the roundish, not so triangular head.

Only 1 species:

P. modesta Harris (= *cablei* Reizst., *occidentalis* Edw., *populicola* Bsd., *princeps* Wkr.) (97 f) is a very *modesta*. variable species, from whitish-grey to light brown, with two notched transverse lines enclosing the median area, hindwing from pink to brown with a dark anal spot. Several subspecies distributed over the whole nearctic region. The nomenclatural type is the common eastern form, forewing more darkened distally to the anterior transverse line, the pink colour of the hindwing densely covered with brown. Canada to Louisiana, to the west as far as California, Oregon and Brit. Columbia. — **occidentalis** Edw. (nec Drc.) is probably a lighter *occidentalis*. summer-breed of the same race. — **imperator** Stkr. (97 f), from Arizona, is large, coarsely scaled, with a large *imperator*. light stigma at the cell-end, the transverse lines more undulately dentate, the pink of the hindwing reduced, the light inner-marginal area increased, the interior one of the two blackish anal spots long and narrow. The nomenclatural type refers to the spring-form with greyish-white forewings, the median band is somewhat greyer, often with a reddish-yellow tinge. — **kunzei** R. & J. is the summer-form which is still lighter, the forewing *kunzei*. more yellowish-white, the transverse lines much less distinct or quite extinct, the two anal spots of the hindwing scarcely contrast with the yellowish-white ground. Arizona, and besides in Colorado, Sonora, and Lower California. — **borealis** Clark, on the contrary, is still darker than typical *modesta*, especially on the thorax *borealis*. and abdomen above and in the broad median band of the forewing. Manitoba. — **regalis** R. & J. is as large *regalis*. as *imperator*, of a more monotonous and darker colouring with a more reddish tinge, the basal area not so contrastingly light; discal lines distinctly undulate-dentate, the distal margin also less undulated, the marginal area less grey. The red colour on the hindwing is extensive, the inner-marginal area blackened. North Mexico (Jalisco and Durango). The intensely granulated larva with transverse pads on the 3 first segments and a very short horn lives on *Populus* and *Salix*.

25. Genus: **Monarda** Drc.

The only species, apparently very local and extremely rare, has hardly become known hitherto. Proboscis stunted, palpi very small, coarsely haired like the basal part of the inner margin on the wings. Antennae long, bipectinate in the ♂, tibiae spineless. Wings broad with rounded margins. Frenulum present.

M. oryx Drc. (97 f) is a most peculiar species. Forewing dark brown, covered with rusty brown scales, *oryx*. the veins broadly olive; double antemedian and postmedian transverse bands are blackish and interrupted by the veins. Hindwing pale reddish, smoky at the margin, with a dark, almost straight transverse band. The species was originally described from Jalisco (Guadalajara), later on it was found near Tlalpam and in Cholula and Puebla in the valley of Puebla (cf. the report of CARLOS C. HOFFMANN in Rev. Mexicana d. Biologia, 1922, p. 17 sq.); the specimens from the valley of Mexico (Tlalpam) are browner than the intensely blackened Puebla-specimens. Mr. HOFFMANN had the kindness to present us with a specimen for having it figured.

26. Genus: **Cressonia** Grt. & Rob.

Proboscis short and thin; palpi of ♂ long, divergently bent, of ♀ shorter; tibiae spined; pulvillus present. Distal margin of forewing undulate; costal margin of hindwing straight at first, somewhat lobate beyond the centre. Antennae almost Saturnid-like.

Only 1 species:

C. juglandis Abb. & Sm. (= *hyperbola* Sloss., *instabilis* Martyn, *pallens* Stkr., *robinsoni* Btlr.) (97 f). *juglandis*. The brownish-white ground-colour is of a most variable tint, with a slightly angular subbasal line, a straight antemedian line which, together with the more oblique undulate postmedian line, encloses the median area being darker brown in the proximal half, with a brown discal streak; terminal area brownish enclosing a curved, broadly faded light subterminal line. Hindwing with 2 antemedian lines and a postmedian shaded band. Larva green or reddish with lateral oblique stripes anteriorly bordered with red, frequently with red spots before

them. Head two-pointed triangular, horn long, feebly curved. It lives on Juglans, Ostrya. Canada to Florida and Texas, to the west as far as the Mississippi.

B. Sphingidae semanophorae (with a scent-patch inside on the basal joint of the palpus).

Subfamily: **Sesiinae**.

1. Tribe: *Dilophonoticae*.

27. Genus: **Pseudosphinx** *Burm.*

Scarcely separable from the following genus in structure, but of a very different exterior; hair-tuft on mesothorax somewhat higher, but more sharply interrupted posteriorly, the whole metathorax shorter.

Only 1 species:

- tetrio*. **P. tetrio** *L.* (= *plumeriae* *F.*, *hasdrubal* *Cr.*, *asdrubal* *Poey*, *rustica* *Sepp.*) (98 a). One of the commonest *Sphingidae* with most gigantic females, the ♂ darker than the ♀, whitish-grey, with brown, very irregular linear markings, the ♂ with a brown basal spot at the costal margin and a brownish area behind and below the cell, a strong black discal streak and a black streak terminating into the distal margin far below the apex. Hindwing blackish-brown, whitish-grey at the anal angle with dentate lines therein. Intensely darkened blackish-brown ♂♂ belong to — **obscura** *Btlr.* — Larva of a very striking colouring, black, with yellow segments, red head, feet and anal segment, and a long thread-like horn; it lives gregariously on Euphorbiaceae and Apocynaceae, especially on *Plumeria*. According to observations by MILES Moss it seems to remain unmolested by parasites, whereas v. BÖNNINGHAUSEN states it to be much stung by parasitic flies. The pupae are found covered in leaves that have dropped to the ground and have been spun together with few silky threads. Very widely distributed from Florida across the West Indies, to the south as far as Paraguay and South Brazil.

28. Genus: **Isognathus** *Fldr.*

Of almost the very same structure as *Pseudosphinx* and *Erinnyis*; strongly built, thorax with a low tuft. Margin of forewing slightly undulate-dentate, hindwing yellow. Several similar species.

Type: *I. scyron* *Stoll*.

- leachi*. **I. leachi** *Swains.* (= *cahuchu* *Bsd.*, *metascyron* *Btlr.*, *scyron* *Wkr.* part., *pedilanthi* *Bönningh.*) (95 d). Dark wood-coloured brown, mixed with grey and black, slightly strewn with greyish-white, a dark basal spot is about 2½ mm broad; cross-vein light, a dark cellular spot before it, another round spot behind it, the black streak between 3 and 4 is very thick, more or less connected with a curved spot above 2; without grey vein-streaks in the postmedian area. Hindwing ochreous as in all the species, with a regularly dentate marginal band. Abdomen unicoloured. Larva — at least probably — brownish-black and with grey spots, with a filiform caudal horn and a red head; on *Plumeria*. Surinam to Southern Brazil.
- swainsoni*. **I. swainsoni** *Fldr.* (= *fumosa* *Btlr.*, *scyron* *Wkr.* part., *pedilanthi* *Bönningh.* part., *zebra* *Clark*) differs from *leachi* in the increased white irroration and interrupted whitish-grey vein-streaks in the postdiscal area; the two spots in and behind the cell-apex are confluent, the basal spot is narrower, and the space between veins 2 and 3 less dark brown; marginal spots at the ends of the veins larger and lighter grey. The marginal band on the hindwing is broader and only very little inwardly dentate, or not dentate at all. Surinam to Southern Brazil. Larva black, with white segments and red head, anus and abdominal legs, the filiform horn enormously long. It lives on *Plumeria*.
- scyron*. **I. scyron** *Stoll* (= *pedilanthi* *Bsd.*) (95 e) has a distinctly banded abdomen, ground-colour more reddish-brown, ventral side dingy reddish-white. Postdiscal area of forewing with a grey vein-stripe interrupted by black dots; disc of ♂ with 2 black spots in a reddish area between 4 and 2, absent in the ♀. Venezuela to Para, Trinidad.
- menechus*. **I. menechus** *Mén.* (= *amazonicus* *Btlr.*, *pelops* *Bsd.*, *rimosa* *Bsd.*, *scyron* *Wkr.* part.) (95 f). Well characterized by the peculiar bluish-grey ground-colour, very strongly built body and distinctly banded abdomen; forewing with double antemedian and discal transverse lines which are more distinct at the costal margin, interrupted on 5, concave below it and connected with the antemedian pair, so that a half-ring is produced, which is open towards the inner margin. Larva similar to that of *Ps. tetrio*, with white segments, orange-red head, abdominal legs and anal segment; according to MILES Moss the segments are not white, but spotted red. On *Artocarpus*. Surinam to Espiritu Santo.
- rimosa*. **I. rimosa** *Grt.* (95 c). Forewing and thorax chalky greyish-white, abdomen with distinct bands. Forewing with large white marginal spots. Hindwing lighter yellow. The species is most variable and divided into many subspecies. The collar of the nomenclatural type is not striped brown, the black basal spot of the

forewing is absent or very small, the black marginal band of the hindwing is broad and extends almost to the cell; the ♀ is without the black discal longitudinal streak. West Indies, Cuba, Haiti. — **inclitus** *Edw. inclitus*. (= *scyron* *Dic.*) (95 c) is the form from Mexico, Yucatan, Honduras, Costa Rica and Panama; collar striped brown, forewing much more intensely marked blackish-brown, the marginal band of the hindwing narrower; the ♀ is more dusted with black, especially at the inner margin. — **papayae** *Bsd.* (= *laura* *Btlr.*, *papayae*. *scyron* *Wkr.* part., *silenus* *Grt. & Rob.*) is much smaller, forewing of both sexes intensely marked brown and white; marginal band of hindwing narrower. Venezuela, Guiana. — **brasiliensis** *Clark* (95 f) is very closely allied *brasiliensis*. to *papayae*, but more monotonously greyish-brown and less marked, ground-colour not white. Abdomen with less intense bands. — **wolcotti** *Clark*. Marginal band of hindwing only half as broad as in the other insular *wolcotti*. forms; ground-colour of forewing brown, both wings beneath with a very conspicuous broad light grey marginal band. — **occidentalis** *Clark* (= *amazonica* *Clark*) is intermediary between *papayae* and *brasiliensis*. *occidentalis*. Thorax above dark brown, abdominal bands likewise brown, not black; ground-colour of forewing chalky white as in *papayae*, with less conspicuous white marginal spots, the black subbasal longitudinal streak distinct. Hindwing light yellow with a broad monotonously dark marginal band. Amazons. — **molitor** *R. & J.* *molitor*. has very light whitish-grey body and wings. The yellow areas beneath are reduced, sharply defined, distally bordered by a black band. Haiti. — **jamaicensis** *R. & J.* has grey forewings with a feeble rosy tint; *jamaicensis*. margin of hindwing very broad, the grey anal spot almost entirely lacks the black lines. Jamaica. — **congratulans** *Grt. & Rob.* (= *rimosa* *Gundl.*) (95 f) has almost quite blackish-brown forewings above; margin of hindwing very broad, extending almost to the cell. Ventral side grey mixed with brown. According to RAMSDEN it is only a form of *rimosa*. From Cuba. — **woodi** *Ramsden* is likewise a dark blackish-brown form from Cuba, *woodi*. but with a light grey broad postdiscal band.

I. excelsior *Bsd.* Upper surface similar to the form *inclitus* of the preceding species, but easily separable from it and all the other species by the purely white, black-spotted ventral side of the abdomen. A remarkable species, the basal two thirds of the forewing blackened, the apical third chiefly white, marked black. Brazil (Pará). Larva very similar to that of *leachi*, but the spots are light reddish. Horn longer than half the larva.

I. australis *Clark* (98 a). A smaller light species, the forewing with an intense brownish tint, with few contrasts, and very fine markings. Marginal band of hindwings of medium width. The species is very near to *rimosa* f. *papayae*. From Eastern Brazil (Uruahy).

I. allamandae *Clark* is very near to *australis*, but with narrower wings; forewing grey above, intermixed with white, with darker markings, colouring still more monotonous, the black discal longitudinal streaks thicker than in *australis*, absent in the ♀. The convex distal margin is more intensely undulate-dentate. The black marginal band is narrower than in *australis*. From Pernambuco and Pará. Larva similar to that of *mossi*, but the lateral stripe is narrower and striped red, the red dorsal and subdorsal lines are broader. Head black. On Allamanda.

I. caricae *L.* (= *cacus* *Chr.*) (98 a) is distinguished from all the similar species by the black-striped veins in the distal half of the yellow hindwing; without a marginal band, only with a small subanal spot. Strongly built, abdomen with strong bands; forewing intensely blackened, with very distinct deep black transverse lines, discally with red-brown longitudinal patches. Venezuela to Rio de Janeiro. Larva black with a yellow band on the neck, yellow sublateral lines and a red head. It lives on Allamanda.

I. mossi *Clark* (95 f) is the most similar to *menechus*, but of a much darker colouring. Body brownish-grey, abdomen with distinct bands. Forewing monotonously brownish-grey, strewn with white, transverse lines very distinct, half-ring above the centre of the inner margin, similar to that of *menechus*. The black band of the hindwing is 10 mm broad, leaving free the anal angle. Manaos, Pará. Larva black with a white lateral band and red longitudinal lines and a yellow head, on Plumeria.

29. Genus: **Erinnyis** *Hbn.*

Hindhead with a high double tuft, mesothorax also with such a tuft which is higher than in *Isognathus*; ♂ with a tripartite anal tuft; legs long and slender. Margin of forewing regularly undulate-dentate. Sexes mostly very different, ♂♂ much darker than ♀♀.

Type: *E. ello* *L.*

E. alope *Dru.* (= *edwardsi* *Btlr.*, *fasciata* *Swains.*, *flavicans* *Goeze*, *scyron* *Burm.*) (98 b) differs from *alope*. all the others in the yellow hindwings. Forewing predominantly black, of brownish wood-colour at the inner margin and in the anal-marginal part, with very oblique transverse lines. Hindwing yellow in the basal portion, black distally. Larva brown above, green beneath, the two colours separated by a black line, a large black spot enclosing a red ring is on the 3rd thoracal ring. Horn short. It lives on *Carica* and *Jatropha*. Widely distributed from Florida to South Brazil and Argentina, also in the West Indies and Bahamas.

E. lassauxi *Bsd.* has the blackest wings among the species with a black-ringed abdomen. Hindwing deeper red than in the other species, very often darkened blackish-brown; easily recognizable by the trian-

gular light costoapical spot of the forewing. The nomenclatural type from Venezuela to Argentina has the darkest, blackish-brown hindwings without any rusty red. — *omphaleae* Bsd. (= *cercyon* Burm., *picta* Ky., *piperis* Schauf.) (98 b) has a deep cinnamon-red basal spot on the hindwing. Mexico, Costa Rica, Colombia, *merianae*. Venezuela, Bolivia, Argentina; Jamaica. — *merianae* Grt. (= *janiphae* Bsd.) has a much narrower margin of the hindwing than the two preceding forms; abdomen beneath spotted black as in the preceding forms. *impunctata*. West Indies, Florida, Central America. — *impunctata* R. & J. is smaller on an average, otherwise similar to *merianae*, but the ventral side is not spotted black and lighter. Venezuela to Argentina (Tucuman). Larva very conspicuous, hornless, green with a brownish-white dorsal stripe on the 6 posterior segments, and 4 oblique stripes directed posteriorly downwards on the 6th to 9th segments, with large white knob-like swellings on the thoracal segments, copying the milk-drops of the food-plant, an Asclepiadea.

ello. **E. ello** L. (98 b, c) is presumably the commonest Sphingid in South America. Forewing grey, the ♂ with a black longitudinal stripe from the base of the inner margin towards the apex, the ♀ without it. Abdomen with very strong bands. Larva green or brownish with a light lateral stripe, and with or without a brown saddle-spot on the thoracal segments; the horn is merely a tiny knob. It lives on various Euphorbiaceae. Found in the whole of America, wandering to the north as far as Canada.

yucatan. **E. yucatan** Drc. (98 c) is larger, with broader wings, of a purer whitish-grey, the ♂ more clearly marked, the ♀ with less marking; the longitudinal stripe of *ello* is interrupted here several times. Hindwing without a sharply defined marginal band. Abdomen without bands. Mexico and Costa Rica.

oenotrus. **E. oenotrus** Stoll (= *hippotoon* Burm., *melancholica* Grt., *penaeus* F., *picta* Sepp, *piperis* Grt. & Rob., *sthen* Gundl.) (98 c) is also a very common species; ♂ blackish-brown, marked grey, ♀ whitish-grey, marked blackish. The border of the black large basal area between the median branches in the ♂ is somewhat concave, the marginal band of the hindwing coherent. Abdomen spotted black beneath. Larva green, lighter or brownish on the dorsum, with darker dots or spots, on Apocynae, where it is often found in a Geometrid-like attitude.

crameri. **E. crameri** Schs. (= *oenotrus* Grt., *omphaleae* Btlr.) (98 c) differs from *oenotrus* in the lighter metathorax and spotless ventral side; margin of hindwing more distinctly defined. Larva green or slaty bluish, dotted darker, with red spots on the 2nd and 3rd segments, on Apocynae. Mexico to Paraguay and the West Indies.

obscura. **E. obscura** F. (= *cinerosa* G. & R., *phalaris* Ky., *rustica* Schaller) (98 d) is a small and most variable species, different in the sexes, the ♂ showing a dark longitudinal band through the forewing and an oblique subanal streak, both of which are absent in the ♀, though the two sexes may also become similar. The sexes of the nomenclatural type are dissimilar, the ♂ has a darker thorax than the ♀ and exhibits the black longitudinal stripe from the base to the apex. Distributed over the whole tropical and subtropical regions of America, occasionally to the north as far as Canada. Specimens from Haiti, Cuba and also from the continent with

rhaebus. a brownish thorax and distinct brown markings on the forewing are: — **rhaebus** Bsd. In the Tring Museum *sthen*. there is a specimen the habitat of which is not stated and which fits well to — **sthen** Hbn. The forewing is much shorter here, the dark longitudinal band is broadly interrupted in the centre, and the apical part is connected with the subanal streak, forming a submarginal band; also slightly different in the genital apparatus. According to CLARK from the Antilles and Barbados. — **pallida** Grt., from Jamaica, Cuba, and Haiti,

pallida. are pale specimens with traces of the dark longitudinal band in the ♂, the subanal streak being quite absent. — **conformis** R. & J. is small, the ♂ is also without the dark longitudinal band and has a light grey thorax like the ♀; marginal band of hindwing darker, the row of dots before it very intense. Galapagos Is.

socorrensis. — **socorrensis** Clark is still smaller and of a much more monotonous grey colouring and scarcely marked, ♂ and ♀ almost the same, the longitudinal stripe of the ♂ only marked by a fine line. Marginal band of hindwing above very narrow, the row of dots before it indistinct. Revilla Gigedo Is., on the western coast of Mexico. Larva green or light brown. Thoracal segments thickened and with a fine black dorsal line, with black dots on the other segments; on a creeping Asclepiadea (*Gonolobus*).

domingonis. **E. domingonis** Btlr. (= *fest* Edw., *rhaebus* Drc.) (98 d) has the same size and colouring of the hindwing as *obscura*, but the forewing of both sexes is brownish-black for the greatest part, grey patches only remaining in the centre and subapically at the costal margin, and at the distal margin; the black longitudinal stripe of the ♂ is not prominent owing to the dark ground-colour. From Texas to Paraguay and South Brazil, and in the West Indies. Larva unknown.

guttularis. **E. guttularis** Wkr. (= *pallida* Bsd., *suillus* Bsd.) (98 d) is the smallest of the species, the forewing very similar to that of *obscura*, but the hindwing is only traceably coloured rusty red, and white beneath in the proximal part. Genital apparatus very different. Larva unknown. Haiti and Cuba.

30. Genus: **Grammodia** R. & J.

Chiefly distinguished from *Erinnyis* by the smooth, not undulate-dentate distal margin of the forewing and a very feeble thoracal tuft. Only 1 species.

G. caicus *Cr.* (= *cacus* *F.*) (98 d) is easily recognizable by the light linear markings behind the cell-end *caicus*. of the forewing and the bright red-brown hindwing the marginal band of which is divided into vein-spots. Abdomen above with dark bands. Larva reddish, light brown or light green with blackish or reddish subdorsal lines and lighter lateral stripes; until the last moult it has a straight black horn, after that only a slight protuberance. It lives on Apocynae (Echites, Zschokkea). Distributed from Florida across the West Indies to Central and South America as far as Buenos Aires, but absent in Mexico.

2. Tribe: *Sesiicae*.

31. Genus: **Pachylia** *Wkr.*

The genus contains a number of large, stout species with rather broad wings, the non-angular forewing with a pointed apex. Palpi smoothly scaled, antennae long with a long slender terminal hook. Thorax tuftless, ♂ abdomen with a triangular anal tuft; distal edge of the dorsal segments with a series of long thorns alternating with short ones, though the latter may also be absent.

Type: *P. ficus* *Wkr.*

P. ficus *L.* (= *crameri* *Mén.*, *lyncea* *Clem.*, *venezuelensis* *Schauf.*, *undatifascia* *Btlr.*) (98 e) is one of *ficus*. the commonest American *Sphingidae*, olive brownish with darker notched transverse markings which are mostly inconspicuous, and a large light subapical spot of the forewing; hindwing ochreous with a black median band and marginal band, and a small white spot at the anal angle of the hindwing. A somewhat darker and usually smaller form is: — **aterrima** *Bönnigh.* Larva green or grey mixed with reddish, with yellow *aterrima*. subdorsal lines and with oblique stripes which, contrary to the other Sphingid larvae, extend from in front above to behind below. Before the pupation it turns slaty blue beneath, orange above. It lives on many species of *Ficus* and on *Artocarpus*. Distributed from Florida and Texas across the West Indies to Buenos Aires.

P. syces *Hbn.* (= *ficus* *Stoll*, *inornata* *Clem.*) (98 e) is similar, darker, more indistinctly marked, still *syces*. with a light costal-marginal triangle in the centre, which is rarely connected in the type with a small inner-marginal spot, forming a light median band. Hindwing unicoloured brownish-grey, likewise with a white anal dot and without a median band. Mexico to South Brazil and Bolivia. The form: — **insularis** *R. & J.* *insularis*. (= *ficus* *Wkr.* part., *syces* *Btlr.* part., *inornata* *Grt.*) is distinguished by the non-interrupted light median band of the forewing. West Indies, Jamaica, Haiti. — **cubensis** *Closs* is much smaller, monotonously dull *cubensis*. brown; only the light apical spot is distinct, the light median area only indicated at the costal margin, without the notched lines before and behind it. Larva similar, but it does not turn orange above before the pupation, but exhibits broad jet-black saddle-spots on each segment.

P. darceta *Drc.* (98 e) is the rarest of the 3 species, without the light subapical spot, more reddish- *darceta*. brown with 3 dark oblique stripes, the first proceeding at the costal margin 1 cm behind the base and extending to the first third of the inner margin, the second beginning at the costal margin 5 mm behind the first stripe and extending towards the anal angle, the third from the centre of the costal margin to the centre of the distal margin, a thick discal dot at the cell-end. Hindwing as in *syces*, but without the white anal dot. Panama to Bolivia and Pará. Larva still unknown.

P. resumens *Wkr.* (= *inconspicua* *Wkr.*, *tristis* *Mén.*, *versuta* *Clem.*) (98 f). Likewise an extremely *resumens*. common, smaller species, more reddish brown on the hindwing, marginal area usually somewhat darker, above the more or less distinct transverse markings similar to those of *ficus* there are 2 oblique very indistinct shadowy bands in the same direction as in *darceta*. Hindwing as in *ficus*, but without the white anal dot. Larva similarly coloured and marked as that of *ficus*, but more whitish on the dorsum and without subdorsal lines. Florida to Buenos Aires, Paraguay, Parana; West Indies.

32. Genus: **Oberthurion** *Clark.*

Closely allied to *Pachylia*, eyes large, not ciliated. The thorns of the distal tergite-margins in one row, very strong and long; antennae more club-shaped with a long thick and obtuse terminal hook. Distal margin in both wings undulate between the veins, especially on the forewing the costal margin of which is extraordinarily bent downwards before the apex. Only 1 species:

O. harroverii *Clark.* Body dark brown above, lighter, wood-coloured beneath. Forewing above wood- *harroverii*. coloured with darker margins and a dark brown subbasal dot behind which there is an irregular line almost vertical to the inner margin; double anterior transverse lines enclose a dark brown band of 2—3 mm width; a thick brown spot at the cell-end; posterior transverse line curved S-like, a brown area behind it between vein 3 and the inner margin; 2 dark lines towards the margin; marginal area darkened enclosing a triangular light costal-marginal spot. Hindwing wood-coloured with a dark inner-marginal band and a white anal spot. Length of forewing: 47 mm. Costa Rica.

33. Genus: **Oryba** Wkr.

Similarly stout species as in *Pachylia* with very large projecting eyes which are not eiliated; palpi slender; antennae distinctly club-shaped with a long filiform terminal hook. Basal sternit of abdomen strongly spined. Shape of wings almost the same as in *Pachylia*.

Type: *achemenides* Cr.

kadeni. **O. kadeni** Schauf. (= *imperialis* Drc., *robusta* Bsd.) (98 A a) is a large beautiful species, dark green, more yellowish-green in the marginal area with a concave blackish-brown submarginal band which is lighter violettish-pink especially towards the inner margin; a broad darker green band in the centre of the wing is finely bordered with white proximally. Hindwing of similar colouring and marking. Panama to Bolivia and South Brazil. The gigantic larva is of a glaring ochre colour with large quadrangular black subdorsal spots, and whitish and black oblique stripes below them in the same direction as in the larvae of *Pachylia*; a dark brown variety with whitish bands also occurs. It lives on *Palicourea*, a Rubiaceae with tufts of red and white blossoms.

*ache-
menides*. **O. achemenides** Cr. (= *robusta* Wkr.) (98 A a) is very similar, but more unicoloured and darker, the marginal area violettish-grey, much narrower, the median band scarcely darker, not bordered with white proximally. Basal abdominal segments much more extensively and glaringly golden yellow on the sides. Larva very dissimilar to that of *kadeni*, with enormously widened thoracal segments in the shape of a trilateral pyramid; cadmium-yellow with small black dorsal spots, green subdorsal lines and green and white spots below them. A dark brown variety may occur here, too. It lives on *Ouroparia*, a creeping Rubiaceae with strongly bent thorns. Honduras to Bolivia and North Brazil.

34. Genus: **Leucorhampha** R. & J.

Distinguished from the preceding ones by the forewing being angled on vein 4 and the less stout build. Antennae slender. Forewing with a silvery longitudinal mark on the base of vein 4. Abdomen with long strong conical spines on the distal tergite-margins; end of ♂ abdomen with a tripartite anal tuft.

Type: *L. triptolemus* Cr.

*tripto-
lemus*. **L. triptolemus** Cr. (98 A a). The silvery mark on the forewing is 4—5 mm long and forked at the proximal end; ground-colour light reddish lilac brown with dark brown markings and a long yellowish-white inner-marginal streak, a blackish-brown spot above the anal angle is notched thrice distally. From Mexico to Brazil. Larva greenish-yellow with a fine green dorsal line, a very short horn and a brown anal segment. Ventral side brown, thoracal segments very much swollen; by its terrifying attitude the larva presents a wonderful example of mimicry, turning its ventral side towards its enemy, inflating the thoracal segments still more and strikingly copying a snake's head by 2 large black round eye-spots. It lives on species of *Echites* (Apocynae) and also occurs in a brown variety.

diffusa. **L. diffusa** R. & J. is very closely allied to the preceding species and chiefly differs in the much shorter (3 mm) silvery mark not being forked. Wings broader. Distal margin more strongly dentated, ground-colour darker; basal area and disc of forewing dusted with bluish-white like the hindwing in the submarginal area. Under surface redder than in *triptolemus*. Length of forewing: 45—47 mm. Colombia, Bolivia.

ornatus. **L. ornatus** Roths. (= *triptolemus* Bsd.) shows the yellow abdominal rings reduced to small dorsal spots, whilst they extend around the whole abdomen in the two preceding species. The silvery mark is shorter than in *triptolemus*, only 3 mm long, likewise forked. The ground-colour is more or less covered with greenish-yellow scales exhibiting a bronze reflection. The larva entirely resembles that of *triptolemus*, but it is generally browner and more intensely marked grey. It lives on *Zschokkea* (Apocynae). Colombia to Rio de Janeiro.

longistriga. **L. longistriga** R. & J. (98 A b). Externally very much like *triptolemus*, but the proximally forked silvery mark is 10 mm long and extends to beyond the postdiseal line; the black submarginal band extends from the apex to vein 4. Hindwing sealed rusty brown submarginally almost to the costal margin. Brazil, Sa. Catharina.

35. Genus: **Madoryx** Bsd.

Very near to the preceding genus, separated by a series of alternately long and short thorns at the posterior edges of the posterior segments of the abdomen above. The 4 species are likewise marked with silvery spots on the forewing.

Type: *M. oiclus* Cr.

oiclus. **M. oiclus** Cr. (= *faunus* Bsd.) (98 A b). Forewing silvery grey with a slight lilac tint; 2 silvery spots in the darkened brown disc, the lower spot roundish quadrangular, the upper spot upright crescentiform;

another dark brown spot at the base does not reach the inner margin and encloses a silvery white spot. Mexico to Rio de Janeiro. Larva not described.

M. pluto *Cr.* (= *deborrei* *Bsd.*, *plutonius* *Hbn.*) (98 A b) is easily distinguished from the other species *pluto*. by the pointed apex of the forewing not being once more produced on 7 and therefore looking truncate; the latter, however, seems to be somewhat the case also in Central-American and Colombian specimens. The colour is a dark purple brown or chocolate; the lower silvery spot is very long triangular, its lower side being longest; no white dot in the dark basal spot. Mexico to Bolivia and South Brazil. The light brownish larva is the most similar to a larva of *Catocala* or, in the resting position, when the middle part of the body is raised arc-shaped, to a Geometrid larva, whilst in the terrifying attitude the thoracic segments are raised and inflated, whereby 2 bluish-black eyespots again copy a snake's head with an opened red mouth. It lives on Melastomaceae.

M. bubastus *Cr.* (= *didyma* *Gmel.*, *lynceus* *Bsd.*, *oiclus* *Burm.*, *parce* *Burm.*) (98 A e) has more olive brown *bubastus*. wings, the scheme of markings rather much like that of *pluto*; a white dot in the dark basal spot; two distinct light postdiscal lines, the interior one being rectangular on 7, the exterior one extending to the apex. The nomenclatural type has a strongly produced apex, deeply concave below it, with a more dentate distal margin. Ecuador and Venezuela to Sa. Catharina. — **butleri** *Ky.* (98 A c) has a less deeply concave and less *butleri*. dentated distal margin of the forewing, the black discal band of the hindwing is narrower. Mentioned from British Honduras, before me from Mexico; according to Moss also in the West Indies (St. Vincent, Sa. Lucia, Martinique), where the larva which has not been described lives on *Tecoma leucoxydon* (Bignoniaceae).

M. pseudothyreus *Grt.* (= *oiclus* *H.-S.*) (98 A c) is easily separated from the other species by the dark *pseudo-* short marginal band below the apex being undulate-dentate inwards; the dark subbasal spot is divided into two *thyreus*. small spots, without the white dot; the lower one of the two silvery spots is angle-shaped, the postdiscal lines are dentate. Florida; Cuba. Larva unknown.

36. Genus: **Hemeroplanes** *Hbn.*

Palpi more pointed than in the preceding genera, the scaling somewhat coarse between the antennae which are slender, not club-shaped. Body smoothly scaled, with a tricuspid anal tuft in the ♂; the ♀ with a long pointed tuft. Hindwing of most of the species reddish ochreous or cinnamon-red. 9 partly very similar species.

Type: *H. pan* *Cr.*

H. nomius *Wkr.* (98 A c) is the only species with dark brown hindwings which are light reddish *nomius*. ochreous only at the base. Forewing deep dark red-brown, with a light cinnamon-brownish triangle at the costal margin and a similarly coloured marginal area ending pointed towards the apex and analwards; a diminutive silvery dot at the cell-end. Larva unknown. Guatemala to South Brazil.

H. pan *Cr.* is the only species with a somewhat truncate apex of the forewing and a dentate margin, the hindwing being red, otherwise rather similarly coloured and marked as *parce*. A smaller species from the Upper Amazons, Pará, Surinam, and British Guiana. Larva unknown. — **denticulata** *Schs.* (98 A d) is *denticulata*. the form from Mexico, which however occurs as far as Peru, with a more deeply dentate margin, hindwing with a broader black anal spot and a less darkened margin.

H. grisescens *Rothsch.* (98 A d) is light bluish-grey, marked brown, more densely dusted brown in *grisescens*. the basal and subterminal areas, with a blackish median band close before the silvery spot. Hindwing cinnamon-red with a black anal spot. Hitherto only known from Argentina.

H. gracilis *Jord.* Size and colouring similar to the ♂ of *grisescens*, but the margin of the forewing is *gracilis*. still deeper concave below the apex; the dark median band extends more obliquely than in *grisescens*, the silvery spot is composed of a thin interrupted streak on the cross-vein and a thicker longitudinal streak in a right angle to it. Hindwing with a more brownish margin, but less distinct anal spot. Cuba. Only 1 ♂ known (type in the Berlin Museum).

H. calliommenae *Schauf.* (= *ellacombei* *Rothsch.*, *pan* *Maass.*, *lutescens* *Btlr.*) (98 A d) is the only *calliom-* species with ochreous hindwings with a blackish-brown margin and a dentate distal margin of the forewing, otherwise resembling *grisescens* in colour and marking, the ♀♀ generally more monotonously coloured, often with a distinct spot of crecents below the costal margin behind the centre; the ♂♂ are browner, often intensely strewn with blackish-brown. Colombia, Venezuela; Haiti. *menae*.

H. parce *F.* (= *galianna* *Burm.*, *licastus* *Stoll*) (98 A d). The reddish-grey ground of the forewing suffused *parce*. with a deep rusty brown, the darkest in the basal and subterminal areas; the discal area with black reticular markings and bluish-white dusting; a thick silvery drop at the cell-end, a small Y-shaped mark is attach-

ed to it outside above; in distinction from *innus*, the light oblique apical streak is slightly bent and is situate at the end nearer to the margin than to the undulate-linear spot which is attached to the costal margin behind the centre. Hindwing cinnamon-red with black and light anal markings. From Florida to Bolivia and South Brazil; West Indies. Larva unknown.

ramsdeni. **H. ramsdeni** Clark is closely allied to *parce* and shows the same marking; smaller, with a more obtuse and shorter apex of the forewing; the costal-marginal spot of the forewing containing the undulate lines is merely a small light brown spot with traces of lunar markings; the silvery mark is only a fine angular mark; a broad dark brown line extends from behind the centre of the inner margin towards the costal margin. Hindwing redder than in *parce*. Length of forewing: 29—30 mm. Cuba.

acuta. **H. acuta** R. & J. Body similar to that of *parce*, but of a more olive tint. Forewing narrower than in *parce*, more monotonously coloured and more sepia-blackish; the two costal-marginal spots are more lead-coloured, the posterior one without the undulate lines of *parce* and *innus*; a lead-coloured inner-marginal spot below the silvery mark; distal area transversely striated black; the light apical oblique line is absent, a lead-coloured spot before the centre of the distal-margin. Hindwing rusty-red with a blackish-brown marginal band. Length of forewing: 32 mm. Amazons (Rio Madeira); Chanchamayo (Peru).

innus. **H. innus** R. & J. (= *galianna* Btlr., *lycastus* Wkr., *parce* Bönningh., *bréthesi* Köhler) (98 A e) is externally very similar to *parce*, but easily discernible by the oblique light apical line which is longer and quite straight and the end of which is nearer to the undulate-line spot than to the margin; this costal-marginal spot is mostly more reddish-yellow than in *parce*. The total colouring is deeper and brighter cinnamon-red; distal margin of forewing much less convex. Mexico to South Brazil and Paraguay. The larva has the usual Sphingid shape and is green with light subdorsal lines and orange-red spiracles, horn short, blackish-blue. It lives on *Ambelania tenuiflora*, an *Apocynae*, and turns red before the pupation.

37. Genus: **Stolidoptera** R. & J.

Very near to the following genus *Aleuron* from which it differs in the palpi not being angled laterally; antennae long and slender, with a long terminal hook; stings of the posterior tergite-margins arranged in one row. Margin of forewing irregularly lobed, costal margin of hindwing very convex and of the same green colour as the forewing, in distinction from the otherwise dark hindwing. Only 1 species:

tachasara. **St. tachasara** Drc. (98 A e) is an unmistakable species with dark moss-green forewings, a somewhat lighter apex, the submarginal band with a lead-coloured reflection, and with quite indistinct darker transverse markings, which are partly filled with a lighter colour especially at the inner margin. Hindwing monotonously blackish-brown excepting the green costal lobe. Larva unknown. Mexico to Venezuela.

38. Genus: **Protaleuron** R. & J.

Head tufted, eyes ciliated. Palpi very large, angled outside as in *Aleuron*. Otherwise similar to the preceding genus, but the hindwing without the lobe at the costal margin. Only 1 species:

rhodogaster. **P. rhodogaster** R. & J. Forewing somewhat like that of *St. tachasara*, but not so strongly lobed, shorter dentated. Dark olive green with 3 antemedian and postmedian transverse lines being distinct and blacker only towards the inner margin. Hindwings dark olive brown like the body above. Very remarkable for its bright pinkish carmine ventral side. Only 1 ♂ from Ecuador seems to be known hitherto.

39. Genus: **Aleuron** Bsd.

Distinguished by enormously developed palpi which are angled laterally. Head and thorax with a central ridge. Eyes small, ciliated, the slender antenna with a long terminal hook. The feeble spines of the posterior tergite-margins not in one row. Distal margin of forewing irregularly lobately dentate.

Type: *A. carinata* Wkr.

carinata. **A. carinata** Wkr. (= *chloroptera* Bsd., *philampeloides* Fldr., *orophilos* Bsd.) (98 A e) belongs to the two species with black abdominal bands, though mostly only 2 or 3 basal ones are visible, the others being covered underneath the segments which are pushed one above the other. Forewing olive brown with a straightly cut off oblique light reddish-brown apical part and a similar median band behind the discal dot; hindwing light reddish-yellow with a black apical part and median band. The dark dentate transverse lines of the ♂ are not present in the ♀, but there are only traces of 2 straight lines, one being submedian, the other postdiscal. From British Honduras to Bolivia and Rio de Janeiro.

ypanemae. **A. ypanemae** Bsd. is similar to *carinata*, but the abdomen is without black bands. Unmistakable on the forewing by the triangular white hyaline spot being situated in the angle between vein 6 and 7

behind which a linear white spot follows. Hindwing reddish-brown with an irregularly dentate olive brown margin. A rare species from Brazil (Petropolis).

A. cymographum R. & J. (98 A e) has the same black abdominal bands as *carinata* from which it differs in much less angular palpi and an undulated distinct white line bordering proximad on the lighter apical portion which extends angled, not retilinearly proximad. Bolivia (Rio Songo).

A. chloroptera Perty (= *disis* Bsd., *smerinthoides* Bsd.) (98 A e). Hindwing with a lobately projecting costal-marginal portion, especially in the ♂. Abdomen without black bands. Forewing monotonously dirty green which very quickly turns loamy ochreous brown or reddish-brown, with indistinct darker transverse lines, without the light apical portion. Hindwing somewhat diaphanous greenish ochreous with a broad black marginal band. Nearagua to South Brazil and Argentina.

A. prominens Wkr. (= *carinatum* Bsd., *chloroptera* Burm., *promiscus* Burm., *pudens* Bsd., *smerinthoides* Fldr.) (98 A f) is very near to *chloroptera*, but easily discernible by the shape of the wings, the forewing exhibiting a larger rounded lobe on vein 3, which is merely an insignificant dent in *chloroptera*; a whitish scaled spot subapically at the costal margin, and a similar submarginal one in the centre of the distal margin. The marginal band of the hindwing is somewhat dentate, and a deep indenture is before the anal angle. Brazil (Amazons; Petropolis).

A. iphis Wkr. (= *scriptor* Fldr., *volatica* Clem.) (98 A f) is a lighter, more variegated species, light reddish ochreous with a narrow dark median band of the forewing, composed of 4 black lines and bordered basad by 2 white lines. Forewing beneath with a large bright red-brown discal spot extending below the cell towards the base. Base of abdomen with a distinct white belt, the following segment browner than the others. Mexico to South Brazil. The larva — which, however, may also belong to the next species — is green or brown with red subdorsal lines and oblique stripes coherent with them, with red dorsal markings and red pectoral feet. It lives on *Davilla* (Dilleniaceae).

A. neglectum R. & J. (= *iphis* auct. part.) (98 A f) is extraordinarily similar to *iphis* and often confounded with it. It constantly differs in but 1 white line bordering proximad on the median band which contains very much less distinct black lines. The white abdominal segment is very narrow, the next segment not browner than the rest. The discal spot on the forewing beneath is almost black and much smaller than in *iphis*. Mexico to Bolivia and South Brazil.

40. Genus: **Enyo** Hbn.

Very near to the genus *Aleuron* anatomically, from which it only differs in the spined tibiae.

Type: *E. japix* Cr.

E. japix Cr. (= *japix* Wkr.) (98 e) is a smaller species, light olive brownish with a dark brown median band which is straightly bordered proximad and deeply indented distally below the costal margin and submedianly. A large trapezoid dark subanal spot at the distal margin. Hindwing blackish-brown, marked light near the anal angle. A narrow white belt at the base of the abdomen. The nomenclatural type is the northern form with a broader median band, especially towards the inner margin, projecting distally more rounded in the disc. Mexico to the Amazons and Bolivia. — **discrepans** Wkr. (= *japix* Btlr., *succinetus* Fldr., *japix* Bönnigh.), from South Brazil, shows a narrower median band at the inner margin, projecting with a sharper angle in the centre distally, the dark anal spot is larger. Espiritu Santo to Sa. Catharina. Larva green with a brown ventral side, or quite brown with brown subdorsal lines and oblique stripes and a very short horn; it lives on *Davilla rugosa*.

E. pronö Drc. (= *variegata* Roths.) (98 f) is larger than *japix*, more variegated, the deep dark triangular costal-marginal spot is isolated, the median area not much darker olive than the rest of the wing and not straightly defined inside, but by somewhat undulate lines; a round black discal dot at the cell-end, the anal portion of the distal margin contrasts very dark with the apical portion. Hindwing semi-diaphanous with a broad blackish-brown marginal band. Abdomen without the white basal belt. Honduras to Bolivia and Pará. — **fuscatus** R. & J. is the southern form from Sa. Catharina; the hindwing only shows a diaphanous stripe in the cell and one below it, the triangular costal-marginal spot of the forewing is smaller.

41. Genus: **Epistor** Bsd.

Separated from the preceding groups especially by the second palpal joint not projecting angularly distad, and the comb-like thoraeal tuft. The ♂ exhibits a tripartite anal tuft and is extraordinarily dissimilar to the ♀ both in colouring and marking. The species are divided into two sections according to the presence or absence of a subcostal fold filled with small white scent-seales and woolly hair on the forewing.

Type: *E. lugubris* L.

Section I: Forewing of ♂ without a subcostal fold.

lugubris. **E. lugubris** L. (= fegus *Mén.*, fegeus *Cr.*, luctuosus *Bsd.*, lugubus *Bönnigh.*, phegeus *Hbn.*) (98 A f). ♂ above blackish-brown with a purple reflection, a small distinct black discal spot in a reddish-yellow ring, and an oblique double antemedian line which is filled with light reddish-yellow; more or less distinctly reddish-yellow are also the veins in the postdiscal area, which look dotted dark, as they are interrupted by several undulated dark transverse lines; dark spots at the costal margin in the basal half and subapically. The ♀ shows a lighter brown ground-colour, it lacks the basal dark costal-marginal spot, and the discal dot has a more extensive light ring behind which there is an oblique dark area. — **latipennis** R. & J., from Jamaica, differs in the broader wings and less produced apex, the disc of the forewing is more variegated, the postmedian undulate lines are more distinct and darker. The nomenclatural type has a very wide range from Massachusetts to Paraguay and South Brazil, also in the West Indies. Larva green or pink, with light dorsal and subdorsal lines as well as light oblique lateral stripes bordered darker above; large black spots may occasionally occur between the latter. It lives on vine and *Cissus*.

ocypete. **E. ocypete** L. (= camertus *Cr.*, daunus *Cr.*, lugubris *Willgr.*) (98 A g). The ♂ is at once discernible by the very dark purple blackish-brown wings with a glaringly contrasting yellowish-white inner-marginal pad of the hindwing. The darker marbled forewing only shows the treble light oblique antemedian line and a lighter narrowly crescentiform marginal spot and the inconspicuous discal dot surrounded by reddish yellow. The ♀ is lighter brown, otherwise similar to that of *lugubris*, but the distinct and more oblique antemedian line is bordered with dark distally as far as the inner margin; the discal spot is situate in a light slate-blue spot in which the veins are prominently lighter. the marginal crescent is lighter reddish-brown, the second abdominal segment bears a dark brown belt. Mexico to Paraguay and South Brazil; Cuba, Haiti, Jamaica. Larva very similar to that of *lugubris*, but more intensely granulated white or yellow, the oblique stripes of a purer white. It lives on *Cissus sicyoides* and *Davilla rugosa*.

boisduvalii. **E. boisduvalii** *Obth.* (= camertus *Bsd.* part.) is unknown to me; founded upon 2 ♂♂ from the Coll. BOISDUVAL. In contrast with *ocypete* the mesothorax is lighter than the head and prothorax; the abdomen exhibits a light grey dorsal line between 2 dark brown lines; the 4 wings exhibit a slightly undulated velvety black oblique line extending from the costal margin of the forewing to the anal angle of the hindwing and touching the discal spot which is situate between two black parallel lines; excepting a dark brown costal spot, the antemedian area is light reddish ochreous like the marginal crescent. Patria not mentioned.

Section II: Forewing of ♂ with a subcostal fold.

gorgon. **E. gorgon** *Cr.* (= lyctus *Hbn.*) (98 A g). The ♂ has a very broad subcostal fold extending to the lower margin of the cell. Forewing chocolate brown, deep dark brown below the cell, in a triangular spot behind it and in an apical spot. The ♀ is light reddish brown, partly with a lilac tint, a deep dark brown area thrice angled below in the upper two thirds of the postmedian area in which the large, contrastingly light round discal spot is situate. Mexico to South Brazil, absent in the West Indies. Larva also similar to the two preceding species, with a darker bluish-green dorsum and a dark brown horn and marking on the anal segment, the 4th segment more widened laterally; on *Cissus sicyoides*.

taedium. **E. taedium** *Schs.* is very similar to *gorgon*, but the scent-organ i. e. the subcostal fold of the forewing is much narrower, whereby the costal margin is less convex; distinguished by the more olive brownish ground-colour lacking the dark postdiscal triangular spots; the lower discocellular vein of the forewing is half the length of the distance between the veins 3 and 4. The ♀ is almost exactly like that of *gorgon*, but distinguished by narrower forewings with a more distinctly bent distal margin, a darker ground-colour and the distal margin of the forewing beneath exhibiting a whitish-grey diffuse band. Mexico to Colombia. — In **australis** R. & J. (= lyctus *Wkr.*, *gorgon* *Bltr.*), from Brazil and Venezuela, the lower discocellular vein is shorter than $\frac{1}{3}$ of the distance between 3 and 4; the light marginal crescent is lighter and clearer, the veins in it not striped brown.

bathus. **E. bathus** *Rothsch.* is darker brown than *gorgon* and *taedium*, the abdomen not clothed with woolly scales. Forewing dark brown, the dark shadow below along the fold is confluent with the large triangular discal spot which is larger than in *gorgon*; the dark brown apical spot is broader and shorter than in the allies, the crescentiform light marginal band is narrower. Hindwing less brown; anal angle more produced. Peru and Bolivia.

cavifer. **E. cavifer** R. & J. (= *gorgon* *Bltr.*, lyctus *H.-S.*) (98 A g) has the same narrow shape of the subcostal fold as *taedium*, but it is much darker, of a purple blackish-brown colour, with single bluish-white markings and veins, particularly in the anal area of the forewing; a large triangular area in the distal half of the costal margin as far as the anal angle, distally bordered by the light marginal crescent, is deep dark brown like a spot below the median; a deep oval concavity is near the base of the forewing. Larva like those of the preceding species, but more slender, the subdorsal line undulated, with large light reddish-brown spots between the oblique stripes, bordered above by dark brown. Bred from the egg on *Cissus sicyoides* by MILES MOSS. Panama to Bolivia and Brazil.

42. Genus: **Pachygonia** Fldr.

Distinguished from *Epistor* by the absence of the thoracal comb and by the posterior tibiae being long-scaled dorsally and ventrally, whereby they appear to be flatly compressed. Excepting this latter peculiarity it is also closely allied with *Perigonia* and *Nyceryx*. 5 species:

Type: *P. subhamata* Wkr.

P. subhamata Wkr. (= *caliginosa* Bsd., *gigantea* Schauf., *grandis* Bsd., *nimerod* Bsd., *subtramata* ^{sub-}*Bönningh.*) (98 B a). Forewing dark red-brown with numerous dark transverse lines; a distinct loamy grey ^{hamata.} crescentiform marginal spot below the apex. In distinction with the very similar *caliginosa*, the distal margin is concave below the apex, another concavity is below it between 7 and 5. Hindwing red-brown basally, black distally with dull ochreous bands, occasionally with a reddish tint. Mexico to Brazil and Paraguay. Larva unknown.

P. caliginosa Bsd. (= *subhamata* Wkr.) (98 B a) is exactly like *subhamata* in colour and marking, but *caliginosa.* it has a pointed apex of the forewing and a convex, not concave, distal margin. The under surface is lighter. Central and South America.

P. hopfferi Stgr. (98 B a) is similar to *subhamata* in the shape of the wings, but the forewings are much *hopfferi.* darker brown, so that the transverse markings are much less distinct, the crescentiform light marginal spot below the apex is absent, and the bands of the hindwing are bright carmine. Panama to Bolivia.

P. drucei R. & J. (= *hopfferi* Ky.) (98 D a) differs in the same way from *hopfferi* as *caliginosa* from *drucei.* *subhamata*, i. e. the apex of the forewing is pointed, the distal margin not concave; the light discal spot is larger, the crescentiform light marginal spot below the apex is very distinct; anal angle with whitish scales; the red bands of the hindwing are broader. Panama, Honduras.

P. ribbei Drc. (98 D a) is at once discernible from all the preceding species by the reddish bands of the *ribbei.* hindwing being only represented by rudimentary streaks at the anal angle. Distal margin of forewing dentate. Panama. — **peruviana** Joicey & Talbot is much darker brown above, especially the hindwing, on which the two *peruviana.* light anal streaks are more distinctly marked. Under surface of a more ochreous colour. From the Upper Marañon (Peru), at an altitude of 1000 ft.

43. Genus: **Himantoides** Btlr.

Very near to the preceding genus which it resembles in the peculiar laterally compressed scaling of the posterior tibiae and of the first tarsal joint. Chiefly separated by the anal angle of the forewing not being bent downwards and backwards as in *Pachygonia*, but ending obtusely rounded. Only 1 species:

H. undata Wkr. (98 B a) is a smaller species, forewing brown with a white, black-edged stigma and *undata.* several black transverse bands; the median area enclosed by them is mostly dusted with white towards the inner margin, more blackish-brown towards the costal margin. Hindwing orange with a black base and marginal band. Jamaica. Nothing is known of the life-habits.

44. Genus: **Cautethia** Grt.

Distinguished from the otherwise similarly built *Himantoides* by the shorter antennae and normally scaled posterior tibiae.

Type: *C. noctuiformis* Wkr.

C. spuria Bsd. (98 B a) is the largest species, marked almost exactly like the following *yucatana*, but *spuria.* darker blackish-grey, the basal area still somewhat darker like the band extending from the centre of the costal margin to the anal angle. Hindwing somewhat lighter yellow with a broader marginal band. Genitally different from the following species. Hitherto only known from Mexico.

C. yucatana Clark (98 B a) is the most closely allied to *spuria*, but considerably smaller; forewing of *yucatana.* the same smoke-grey colouring and the hindwing just as light yellow, whereas *grotei* and *noctuiformis* have yellowish orange hindwings; the black marginal band of the hindwing extends to the cell; markings of forewing less prominent, basal area much lighter; a dark band extends from the anal angle obliquely basad to the first third of the costal margin, as in *noctuiformis*. Length of forewing: 16 mm. According to 1 ♀ from Yucatan (Izamal).

C. grotei Edw. (98 B a) is smaller and very much lighter silvery grey than the preceding species; basal *grotei.* area scarcely darkened, distally defined by double transverse lines, a black discal streak at the cell-end; post-

discal lines strongly notched, a black spot above the anal angle, another notched line before the margin. Hindwing orange with a black marginal band. Bahamas and Florida. The larva described by Dyar lives on the Rubiaceae Chiococca.

*noctui-
formis.*

C. noctuiformis Wkr. (= *hipparsus* Grt. & R., *grotei* Gundl.) (98 B a) is more slate-coloured, the basal area darker; a white black-ringed discal spot at the cell-end, a black transverse band behind it extends to the inner margin more vertically before the anal angle and is strongly widened at the costal margin, the marginal area much narrower. Hindwing orange with a variably broad marginal band which occasionally extends to the cell. St. Thomas; Porto Rico; Haiti; Cuba.

45. Genus: **Nyceryx** Bsd.

Very near to the following *Perigonia* from which the species chiefly differ in the dentate distal margin with a subapical concavity. Numerous, partly similar species.

Type: *N. hyposticta* Fldr.

hyposticta.

N. hyposticta Fldr. (= *vega* Bsd.) (98 B b) is the largest species of the genus, so that earlier authors ranged it with the genus *Ambulyx*. It is always easily discernible by the forewing beneath being covered with numerous reddish-yellow spots as far as the base, whilst the basal part in all the other species is without any spots. It is somewhat similar to the following *ericea* above, with some scantily scaled, semidiaphanous spots in the subterminal area. Colombia and Venezuela as far as Bolivia.

ericea.

N. ericea Drc. (= *coffea* Drc.). Forewing light greyish-brown with olive brown undulate transverse lines, the two median ones connected submedianly by a black longitudinal streak, the interior one expanded at the inner margin into a brown triangle; a brown postmedian oblique band from the centre of the costal margin to the anal angle, behind which there is a series of 3 or 4 small white-scaled hyaline spots distally bordered with black; a black crescent below the apex; discal spot scaled white. Hindwing yellow with a black

minor.

marginal band in which there are some small white strigiform anal spots. Honduras to Colombia. — **minor** Clark (98 B b) is smaller, lighter, more silvery grey, the brown antemedian inner-marginal triangle is absent; behind the brown oblique band there is but one small hyaline luna, the others being merely traceable; the black apical luna is narrower; discal spot light brown, not white. The hindwing exhibits a yellow spot instead of the white anal streaks. Brazil (Sa. Catharina).

lunaris.

N. lunaris Jord. is still much larger than *ericea*, hindwing rusty red, not yellow, with a postmedian row of white dots. Forewing of a much warmer colouring and longer shape, with an obliquely truncate apex, without the dent on vein 5, the angle on vein 4 projects less, and the dents on 2 and 3 are very insignificant; 2 discal dots at the cell-end, the blackish-brown marginal area is bordered by a black centrally angled line as far as the anal angle. From Macas (Ecuador).

coffea.

N. coffea Wkr. (= *abboti* Schauf., *boisduvali* Btlr.) (98 B b) is a large strong species, violettish-brown with deeper purple brown transverse markings which are condensed in the median area, forming a band that is widened at the inner margin; a small white-edged discal spot is in the upper cell-angle. Hindwing very well characterized by a black transverse band extending from the anal portion of the broad marginal band to the basal part of the costal margin. Honduras to Rio de Janeiro.

magna.

N. magna Fldr. (98 B c) is somewhat similar to *coffea*, but the hindwing is of a much deeper orange red colour in the costal part and it lacks the black transverse band. Forewing more bluish black, the blackish-brown median band is rather broader at the costal margin than at the inner margin. An apparently rare species from Peru and Ecuador.

tacita.

N. tacita Drc. (98 B b) and the following *eximia* are easily discernible by the forewing beneath being reddish-yellow as far as the base and by the strikingly white marginal fringe of the ventral side of the anal segment of the abdomen. Forewing brown, frequently with an ochreous tint, profusely strewn with silvery bluish scales between the transverse lines; a large brown spot in the centre of the inner margin extends upwards to the cell and at the inner margin basally narrowed to the base. From Mexico to Bolivia. As to the differences from *eximia* cf. the following species.

eximia.

N. eximia R. & J. (= *tacita* R. & J. part.) is very similar to *tacita* in structure and colouring, but it has a different genital apparatus. The dark spot on the forewing above of *tacita* is proximally defined by a distinct straight grey line ending near the upper one of the black cell-apex dots; the forewing of *eximia* is more violettish-brown and the dark spot is extended towards the base with a curved interior edge; the whitish-grey lines are more irregular than in *tacita*; the oblique postdiscal line which extends from the costal margin to the distal margin is less straight than in *tacita*; the whitish-grey curved submarginal line extending from the brown apical spot to the middle distal-marginal dent shows a very distinct white dot in *tacita*, whilst it is absent in *eximia*. The ochreous area of the hindwing is much more extensive than in *tacita*, the dark marginal band at the subcostal vein 3 mm broad at most, 5—6 mm in *tacita*. The under surface is of a brighter colouring in *eximia* and therefore contrasts more with the marginal band than in *tacita*. The white dots on the abdominal sides are larger than in *tacita*. Described from Panama (Chiriqui).

N. maxwelli *Rothsch.* (= *stuarti* *Rothsch.*) (98 B c) is very closely allied to *continua*, but much larger. *maxwelli*. A variegated species with red-brown markings on the light lilac-brownish ground; the red-brown inner-marginal spot does not extend above to the cell and is black especially at the upper end. Apex of hindwing not black but red-brown. Tegulae edged with white; palpus with a distinct white spot. Only few specimens are known hitherto. Peru; Ecuador; Bolivia; Sa. Catharina.

N. nictitans *Bsd.* (= *subaurea* *Köhler*) (98 B c) is similarly coloured above as *tacita*, but at once *nictitans*. discernible by the forewing beneath being dark brown in the basal part and by two distinct dark brown fine longitudinal lines on the ventral side of the abdomen. Hindwing very dark reddish-ochreous, almost rusty brown with 2 more or less distinct median lines ending in a large spot towards the inner margin. Forewing with a small discal spot bordered with white scales on the interior side. South Brazil (Rio de Janeiro to Rio Grande do Sul). — **saturata** *R. & J.* is the Peruvian form of a much deeper ground-colour, but with less reddish- *saturata*. yellow hindwings. Forewing more lobate at the distal margin. The two reddish-yellow postdiscal spots beneath are traversed by brown undulations and much smaller. — **bryki** *Gehlen* is founded upon a specimen from *bryki*. Chanchamayo, which is intensely marked rusty red instead of blackish-brown.

N. continua *Wkr.* (= *distans* *Bsd.*) (98 B c) is a smaller variegated species which is at once separable *continua*. from the otherwise similar *maxwelli* by its smaller size and the entirely black marginal band of the hindwing. The basal costal-marginal area of the forewing is without distinct linear markings. The oblique antemedian band is filled with black; stigma rather large. Hindwing yellow as far as the inner margin. Brazil (Espírito Santo to Parana). — **cratera** *R. & J.* (*maxwelli* *R. & J.* part.), owing to its larger size, is still more similar to *cratera*. *maxwelli*. The upper surface of the body and wings is of a greyer colour, the marginal band of the hindwing is broader and less distinctly defined, and it extends before the orange inner margin to the base; a brown spot below the cell-end and a few more spots behind it. Peru, Bolivia (Rio Songo).

N. alophus *Bsd.* (= *nephus* *Bönnigh.*) is similar to *continua*. Prothorax and mesothorax browner, *alophus*. tegulae not so purely white-edged. Forewing more variegated owing to more distinct linear marking; stigma narrow and oblong; a blackish subbasal band. The nomenclatural type from Brazil. Bahia to Parana, is the darker form showing the antemedian band filled with black. — **ixion** *Burm.* (= *nephus* *Burm.*) (98 B c) is a *ixion*. lighter form in which the antemedian band is not filled with black. Bolivia, Paraguay and Argentina.

N. nephus *Bsd.* Only the typical specimen is known of this species. Coloured very much like *alophus*, *nephus*. but the upper surface shows a broader marginal band of the hindwing. The disc of the forewing beneath is ochreous, traversed by distinct crescentiform lines in the distal part of the costal margin. Genital apparatus different. Brazil.

N. riscus *Schs.* (= *creusa* *Rothsch.*) (98 B d) is a more common species, similar to *stuarti*, but much *riscus*. smaller and with an excavated forewing below the apex. Ground-colour of forewing light reddish-brown with a slaty blackish marginal band defined inside by a deep dark brown arcuate band. Mexico to Bolivia and Brazil (S. Paulo).

N. stuarti *Rothsch.* (= *riscus* *Drc.*) (98 B d) is much larger than *riscus* with darker forewings which are *stuarti*. truncate below the apex and not excavated; the postdiscal linear markings are more bent below the costal margin. The yellow on the hindwing is more reduced. Peru and Bolivia.

N. draudti *Gehlen* (98 C e) is very similar to *stuarti*, but larger and it has broader forewings; ground- *draudti*. colour greyer, not so reddish-brown, metathorax with 2 red-brown hair-tufts. The distal margin of the forewing is more sharply dentate, the apex distinctly concave; the black marginal band is straight, not curved, and proximally accompanied by another feebler parallel line, a greyish-white stripe distally to the marginal band; the other marking is more reduced than in *stuarti*. Hindwing more extensively yellow and the dark brown tints more greyish-black. Length of forewing: 34 mm. Shanusi (Peru, at the sources of the Amazon R.).

N. mülleri *Clark* (98 B d). Near *clarki* *Fassl.* but smaller. Light brown above with a dark brown marking, *mülleri*. without any silvery grey; with a large triangular dark brown inner marginal spot, 3 undulate lines behind it; distal margin similar to that of *eximia*, but more notched in the centre of the margin and at the anal angle. A straight dark brown longitudinal shadow extends from the upper cell-angle to the centre of the margin. Hindwing dark brown with an orange costal-marginal area, with bluish-white scales in the anal area and undulate submarginal lines. Orizaba (Mexico).

N. clarki *Fassl.* Antennae brown, similar to *stuarti*, head, thorax and abdomen lighter than in *coffaeae*. *clarki*. Marking between *coffaeae* and *maxwelli*. Hindwing with a narrow ochreous longitudinal area at the costal margin, which, however, is half as narrow as in *stuarti*; the other marking towards the anal angle similar to *maxwelli*, but more distinct and extending farther in front. Similar to *coffaeae* beneath, but without bluish-grey marginal areas and turning somewhat olive green especially towards the base. Expanse of wings: 60 mm. Bolivia (Rio Songo), at an altitude of 750 m.

46. Genus: **Perigonía** H.-Schäff.

Like *Nyceryx*, but with a non-dentate margin and pointed apex, not excavated below it. Palpi strong, rounded, hindhead with a feebly parted tuft; antenna slender with a short terminal hook. Posterior margin of the abdominal segments with 3 or 4 rows of strong spines. Anal tuft of ♀ truncate, of ♂ with a prolonged middle part. About 10 mostly tropical species.

Type: *P. stulta* H.-S.

- divisa*. **P. divisa** Grt. & R. (98 B h) is an apparently very rare species from Cuba, easily discernible by a distinct white line extending obliquely from the apex of the forewing inwards; behind the centre there is a straight black discal band edged with yellowish-white. The yellow colour on the hindwing extends to the base.
- grisea*. **P. grisea** R. & J. By the sharp dent in the centre of the margin and at the anal angle it almost resembles a *Nyceryx*, but the apex of the wing is pointed. Body and wings grey, forewing with a straight antemedian line, a small cellular dot and a postmedian line which is twice almost rectangularly broken. A straight line extends from the last fifth of the costal margin to the distal margin at the end of vein 3 and is continued along the margin to the anal angle; all these markings are blackish olive. Hindwing yellow almost to the base as in *stulta*, a yellow distal spot also at the inner margin; marginal area grey. Peru; Bolivia.
- pallida*. **P. pallida** R. & J. (98 B d) is very similar to *stulta*, but lighter and with narrower wings, distal margin more broadly rounded in the centre; immediately discernible from *stulta* by a white lateral line on the first palpal joint. Hindwing with a narrower brown margin, the disc deeper yellow. Venezuela and Argentina.
- thayeri*. **P. thayeri** Clark is allied with *pallida*; apex and anal angle of forewing less pointed, distal margin less convex in the centre; colouring very similar, the dark apical line more prominent like the stigma, the markings more contrasting. Under surface lighter, distal band darker. The yellow on the hindwing is less extensive. Length of forewing: 32 mm. St. Vincent.
- stulta*. **P. stulta** H.-Schäff. (= *lusca* Wkr.) (98 B d) varies in the intensity of the grey admixture in the brown colour of the wings; a crescentiform subapical darkening is situated at the distal margin, bordered inwards by a triangular light costal-marginal blotch. Hindwing extensively yellow to the base. Guatemala to Bolivia and Rio de Janeiro. Larva unknown.
- leucopus*. **P. leucopus** R. & J. is very near to *stulta*. Body above reddish-grey, abdominal sides with a series of obsolete grey spots. Shape of wings and markings as in *stulta*, upper surface dusted with reddish grey, the brown lines are therefore somewhat more prominent, the antemedian line is less regular; a crescentiform grey spot at the margin between the apex and the centre; apex of the wing somewhat sharper than in *stulta*. The brown distal margin of the hindwing is narrowed towards the costal margin. From Cuyaba, Matto Grosso.
- lusca*. **P. lusca** Fabr. is a most variable species and all the forms described are connected by transitions so that it is sometimes almost impossible to separate the single forms. The antemedian band of the forewing is not distinctly defined towards the margin, but faded. The yellow band of the hindwing does not extend to the base, it is generally very narrow, frequently quite obsolete. The 5th abdominal segment is mostly scaled grey. The various forms, like *lefebrai* and *jamaicensis*, do not differ genitally, so that it cannot be decided which is a species and which a form. In the nomenclatural type the blackish submarginal line is uniformly bent and not angled, the antemedian dark band is proximally bordered with a very light colour like the disc, too. A smaller form with a yellow anal spot of the hindwing, from Cuba. The inner margin of the hindwing beneath is extensively yellow. — **passerina** Bsd. (= *lusca* Burm.) is a small form, length of forewing 25 mm at most, margin of forewing obtusely angled in the centre, submarginal line irregular, extinct towards the inner margin. The yellow anal spot of the forewing is large above, absent beneath. This is the form from Matto Grosso, Paraguay and Bolivia. — **ilus** Bsd. (98 B d) is larger, the submarginal line also irregular towards the inner margin. The yellow band of the hindwing is narrower than in *passerina*, the inner-marginal area on the hindwing beneath yellow, not so in *passerina*. Both wings beneath extensively rusty reddish-brown, more olive in *passerina*. — **interrupta** Wkr. (= *lusca* Wkr. part., *doto* Schauf., *restituta* Drc.) (98 B e) has somewhat longer forewings, less convex in the centre of the margin; the black submarginal line is more regularly bent and more remote from the margin. The yellow band of the hindwing is narrower than in *ilus*, extending to vein 2; the yellow anal spot above is more or less distinct, absent beneath. Mexico to Bolivia and Peru. — **bahamensis** Clark (98 B h) is much larger, the light grey tints in the basal area, behind the postmedian line and at the distal margin show a distinct bluish tinge, otherwise very similar to *interrupta*. Bahamas. — **restituta** Wkr. (= *lusca* Wkr. part., *affinis* Schauf.) (98 B e) differs from *interrupta* in the much narrower yellow band of the hindwing, the yellow anal spot being almost or quite absent. Mexico to the Amazons. — **tenebrosa** Fldr. (= *restituta* Roths.) (98 B e) lacks all the yellow colour on the hindwing; Venezuela to the Amazons. — **major** Clark is very similar to *tenebrosa*, the yellow is quite absent in the ♀, only traceable in the ♂.

The ground-colour is darker above and beneath. A large, well marked form from St. Vincent, Guadelupe and Dominica. — Moss describes the larva of the form *restituta* to be whitish or apple-green with a narrow white median stripe and 7 oblique white lateral stripes bordered above with dark green, often also yet with black: head and horn bluish-green. When alarmed the front body is raised and 2 or 3 large black and yellow moon-spots are visible on the ventral side of the segments. It lives on Rubiaceae such as *Ourouparia guianensis*, but mostly on *Coffea arabica* and *liberica*.

P. lefebraei *Luc.* (= *lefebvrei* *H.-Schäff.*) (98 B e). Very similar to *lusca lusca* and with the same genital *lefebraei*. apparatus, the dark antemedian band of the forewing is rudimentary, and the hindwing lacks the yellow inner-marginal spot. Larva not described, according to GUNDLACH it also lives on Rubiaceae. Cuba; Haiti.

P. jamaicensis *Rothsch.* likewise resembles *lusca* and its genital apparatus is neither very different, only *jamaicensis*. the elasper is broader. It chiefly differs in a large yellow discal spot on the forewing beneath. Jamaica.

P. glaucescens *Wkr.*, only known from a single type, resembles the form *tenebrosa* of *lusca*. Thorax *glaucescens*. greenish-yellow above, the 5th and 6th abdominal segments spotted white laterally, ventral side lighter than in *tenebrosa*. Forewing with a broad antemedian band distinctly defined on both sides; the brown submarginal line is regularly bent and begins 2 mm distant from the apex at the costal margin. Hindwing without a yellow band, with a reddish-yellow submarginal spot at the anal angle. Haiti.

47. Genus: **Eupyrrhoglossum** *Grt.*

Structure exactly like that of *Sesia*, but veins 7 and 8 of forewing are not fused at the ends. Only 2 species:

Type: *E. sagra* *Poey*.

E. sagra *Poey* (= *harpyia* *Schauf.*) (98 B e) is a most characteristic species; body mouse-coloured above, *sagra*. brown laterally, abdomen with a brown dorsal line. Forewing brown with black markings and a white hyaline spot before the centre of the margin in the black submarginal band which begins about 8 mm before the apex and is sharply broken in the upper third. Hindwing jet-black with a uniformly narrow straight yellow transverse band and yellow fringe. Mexico to Rio Grande do Sul and Cuba. — Larva, according to Moss, brown, dorsally more pinkish-brown, with a darker brown dorsal line and similar 7 oblique stripes on the rings 8—11 with emerald-green spots below them; the black horn is very coarsely granulated. It lives on *Sabicea aspera* (Rubiaceae.)

E. corvus *Bsd.* (= *eculus* *Btlr.*) (98 B f) is much more like a *Perigonias* with very slender and narrow *corvus*. wings. Forewing brown with darker transverse markings and a feebly and regularly bent submarginal band. Hindwing yellow with a black base and marginal band. Nicaragua to Bolivia. Moss presumes the larva to be very similar to that of *sagra*, but green, on Rubiaceae, but it did not develop.

E. venustum *R. & J.* is near *corvus*, but easily separable from it by the broader and much lighter *venustum*. greenish yellow band of the hindwing, by the light maize-coloured pectoral side of the thorax, and by numerous blackish-brown lines on the forewing above. Thorax blackish-brown with 2 lead-coloured stripes. Forewing narrower and longer than in *sagra*, blackish brown, with a leaden gloss between the transverse lines, with 7 antemedian and 5 postmedian blackish brown lines, the latter lines somewhat dentate, in a feeble S-curve, the 5th line being broadest, united with a submarginal line before vein 4 and extending together to the anal angle. Length of forewing: 31 mm. Rio Madeira (Amazons).

48. Genus: **Sesia** *Fabr.*

Head broad, palpi with a short point. Antenna scarcely thickened towards the apex, with a slender terminal hook. Margins of wings entire; the veins 7 and 8 of the forewing are fused at the ends. The genus contains 5 species with a relatively very strong body, anal end with a strong fan-like tail and with relatively narrow and small, though very strong wings. Only American.

Type: *S. tantalus* *L.*

S. ceculus *Cr.* (98 B f) and the following *gehleni* are the only species with a yellow band of the *eculus*. hindwing. Forewing dark brown with a darker basal half and several dark submarginal bands, often with a narrow hyaline subterminal spot which may also be just as often absent. Hindwing black with a narrow orange band widening analwards. Abdomen spotted orange laterally. Mexico to Bolivia and South Brazil. Moss has

described the larva, it lives on the two Rubiaceae: *Oourouparia guianensis* and *Sabicea aspera*, and on each of them in an entirely different form adapted to the plant. The form living on *Oourouparia* is bluish-green, dorsally whitish with 7 white lateral stripes, the first and last of which are broader and whiter; the form living on *Sabicea* is more yellowish-green with chestnut-red lateral stripes and dorsal line and an undulated subdorsal stripe on the first to third segments.

gehleni. **S. gehleni** Closs which is doubtfully regarded as a species is described as follows: closely allied with *cecylus* Cr., the yellow lateral spot on the abdomen only extends to one segment; the dark postdiscal band of the forewing above extends from the costal margin like a wedge with straight margins, not curved; the apical area of the forewing beneath shows a rusty brown, triangular, sharply defined costal-marginal spot followed by a rusty brown rectangular spot which is somewhat faded downwards. Rio Songo, Bolivia. According to GEHLEN it may be only a form of *cecylus*.

blaini. **S. blaini** H.-Schäff. (= *acdon* Bsd.) is a smaller rare species from the West Indies. Forewing black with a whitish hyaline macular stripe; hindwing quite black. Tegulae light-edged inside. Abdomen, contrary to the following species, without a white transverse band on the 4th segment, intensely intermixed with olive yellow. Cuba; Jamaica; Porto Rico.

tantalus. **S. tantalus** L. (= *ixion* L., *sisypus* Burm., *titan* Burm.) (98 B g) is the smallest of the 3 similar following species; well discernible by the traceable or absent light brownish median band of the forewing, composed of 2 or 3 undulate transverse lines, without distinct white spots or only with a very small one; there are always only 3 small white subterminal hyaline spots, the uppermost being the largest and often bipartite. Hindwing without a white anal spot. The ♂ occasionally shows a short yellowish discal band on the hindwing. The nomenclatural form flies from Surinam and Venezuela to Argentina. — **zonata** Dru. (= *terpunctata* Goeze, *tantalus* Wkr., *tripuncta* Btlr.) is very little different, the white subterminal spots are reduced in size and number. Slight genital differences. — **eumelas** Jord. is a special insular form from Jamaica, similar to the Mexican form, jet-black above, head and thorax greenish; palpi white below, pectus creamy whitish like the bases of the wings beneath, sharply contrasting with the abdomen which is not grey at the base and also scarcely shows grey median lines. — **clavipes** R. & J. (= *tantalus* Grt., *Edw.*), from Mexico and Central America, also occurs as an alpine form in the South-American Andes to the south as far as Tucuman. Generally somewhat larger than *eumelas*, the disc of the forewing occasionally with a small white dot. As the structure of the anterior tarsus differs somewhat from that of *eumelas*, JORDAN regards this form now as a distinct species; also slight genital differences. Larva unknown.

titan. **S. titan** Cr. (= *fadus* Btlr., *tantalus* Wkr.) (98 B f) is very near to the following species, but differs in the following marks: there are 4 or 5 small white hyaline spots on the forewing, which are not parted; hindwing more extensively and densely scaled white. The ♂ exhibits 2 thick black scale-tufts on the anterior leg, one at the end of the femur, the second at the end of the tibia. Widely distributed in the whole neotropical region, occasionally it also passes over to North America. — The larva resembles so much that of *fadus* that it is difficult to distinguish, the colour is somewhat more bluish-green, the dorsum more whitish, with a dark green, dorsal line and feeble oblique stripes, the first and last being broader and whiter, the last with a yellow and pink hue. A brown variety occurs, too. It lives on *Randia formosa* (Rubiaceae) and very rarely on *Genipa americana*.

fadus. **S. fadus** Cr. (= *annulosum* Swains., *balteata* Kiril., *tantalus* Wkr., *titan* Burm.) (98 B f) is like the preceding species, but invariably with 4—7 white hyaline spots which are mostly divided into 2 lunae, and without the black tufts on the anterior legs. Range the same as that of *titan*, but also in Cuba and Haiti. — The larva exactly resembles that of *titan*, but it may be somewhat more yellowish green and lives exclusively on *Genipa americana* (Rubiaceae). — **flavosignata** Closs shows a median band on the hindwing dusted yellow from the costal margin. From Blumenau.

49. Genus: **Haemorrhagia** Grt. & Rob.

It comprises the small group of *Macroglossa* which are almost uniformly represented in the northern latitudes of the Old and New World, but are entirely absent in the tropics. Eyes ciliated; antenna club-shaped with a short terminal hook which is suddenly bent downwards. Abdomen with an anal tuft which can be broadly spread like a fan. Anterior tibia with a long terminal spur. Wings entirely margined, more or less hyaline in the disc, strewn with very loose scales, and with a densely scaled marginal band. Genital apparatus of a remarkably unsymmetrical structure.

Type: *H. thysbe* F.

thysbe. **H. thysbe** F. (= *etolus* Bsd., *pelagus* Cr., *ruficaudis* Ky.) (98 B g) is a large species; body olive excepting the 4th and 5th deep dark chestnut-red segments, the 6th segment mostly exhibits such a median spot, anal tuft black laterally, red-brown in the centre. Wings hyaline with a broad chestnut-red marginal band and margins, the former band projecting between the veins with pointed dents and being widened on vein 5. Basal area likewise red-brown with olive hair. The hyaline areas may vary greatly in extent. The nomenclatural form is widely distributed in the Atlantic States as far as the Mississippi. — **cimbiciformis** Stph.

(= *buffaloensis* G. & R., *floridensis* G. & R., *pyramus* Bsd., *uniformis* G. & R.) (98 B g) is the more common spring-form showing the marginal band not inwardly dentate; it flies, however, also in summer. — **fuscicaudis** Wkr. *fuscicaudis*. is another form in which all the segments, beginning from the 4th, are dark chestnut-red, almost black; these forms are connected with each other by all kinds of transitions exhibiting lateral olive green spots on the 6th and 7th segments. Margin of forewing dentate inside. *fuscicaudis* is a more southern form, the usual summer-form of the Southern States, which does not go as far as New England in the north. — Larva green with a dark dorsal line bordered with white, and yellowish subdorsal lines; ventrum with a sharply defined reddish median band. On *Viburnum*, *Symphoricarpos*, *Prunus*, *Crataegus*, and other shrubs.

H. gracilis G. & R. (= *ruficaudis* Wkr.) is a somewhat smaller and very rare species, separated from the *gracilis*. preceding species by the marginal band not being expanded on vein 5; the tiny hyaline spot in the cell-apex is not parted by the fold as in *thysbe*. Hindwing beneath with a yellowish-white spot analwards. Each side of pectus with a rusty brown horizontal stripe which is absent in all the other species. Ventrums cinnamon-red with yellowish-white central spots. Canada, New England. Larva unknown.

H. diffinis Bsd. (= *fuciformis* Abb. & Sm., *marginalis* Grt.) (98 B g). Body olive, abdomen above more *diffinis*. yellowish ochre, laterally and ventral side black, pectus whitish, legs black. Wings extensively hyaline with narrow black margins and a black base; the centre of the anal tuft in the nomenclatural form is of the same colour as the thorax and the two last segments. It is the larger summer form the distal margin of which is somewhat dentate inwards. — **tenuis** Grt. (= *fumosa* Stkr., *metathetis* Btlr., *diffinis* Beut.) is the spring form *tenuis*. the distal margin of which is not dentate, and finally — **axillaris** G. & R. (= *grotei* Btlr., *aethra* Stkr.) is an *axillaris*. autumn breed with a very strongly dentate margin. Atlantic States from Texas to Canada, in the north to the west as far as the Pacific. — **ariadne** B. & McD. (= *senta* R. & J., *rubens* Hanham) is the smaller more slender *ariadne*. race from Colorado. Legs more grey, not black, with yellow hairs on the tibiae, the margins of the wings more reddish enclosing a rusty red apical spot, the inner margin of the hindwing also enclosing a yellowish-grey area. 4th and 5th abdominal segments not with black bands. — **thetis** Bsd. (= *palpalis* Grt.) (98 B g) shows the 6th *thetis*. and 7th abdominal segments light above, generally also the centre of the 5th segment. Hind tibiae with a light hair-tuft at the base, or altogether light-haired. — **rubens** Edw. is the larger summer-form of it with distinctly *rubens*. red-brown margins of the wings. — **cynoglossum** Edw. has quite black hind tibiae and black 4th and 5th ab- *cynoglossum*. dominal segments. The latter 3 forms from the Pacific States, British Columbia to Arizona. — Larva similar to that of *thysbe*, but the dorsal line is not bordered on both sides with light but with dark, and the whole dorsal part has a brownish tinge. It lives on *Symphoricarpos*, *Lonicera*, *Apocynum*.

H. senta Stkr. (= *brucei* French) (98 B g) is very closely allied to the form *ariadne* of the preceding *senta*. species, but it constantly differs in the entirely grey ventral side and grey legs. Abdomen above somewhat more variegated. Colorado and Utah.

Subfamily: **Philampelinae.**

Tribe: *Philampelicae.*

50. Genus: **Pholus** Hbn.

About 20 large Sphingid species with stout bodies, partly very brightly coloured. Proboscis long, palpi large, rounded in front. Eyes large, not ciliated, no tuft between them. Antenna with a slender thin terminal hook. Posterior edge of the abdominal tergites with conical, very long and strong spines. Anterior hips with a strongly developed scent-organ. Larva green or brown with a very much widened 4th segment and oblique stripes extending from in front above to behind below, contrary to most of the other *Sphingidae*. The long horn is S-shaped at first and gradually becomes a roundish protuberance in the growing insect. It lives on vine and *Jussieu*.

Type: *Ph. achemon* Dru.

P. anchemolus Cr. (= *satellitica* var. *Burm.*) (98 C a) is one of the largest species, chocolate brown, in *anchemolus*. the ♂ with a faint pink hue, recognizable by the distinctly creamy white inner margin. The scheme of markings is the same in nearly all the species: an oblique dark trapezoid spot above the inner margin before the centre, dying away inwards, a triangular dark spot in the centre of the costal margin, obliquely continued to the distal margin along vein 3, and a dark preapical spot ending straightly cut off on vein 3. Hindwing greenish yellowish-grey with a light reddish anal angle, a black spot above it, and a broad blackish-brown marginal band. Under surface more or less brick-coloured reddish. — The gigantic larva is green with greenish-yellow broad oblique spots on the 9th to 11th segments, finely bordered with red-brown; small spots of the same colour are on the anterior segments. More rarely also in a claret-coloured form. It lives on *Ampelopsis* and *Cissus*. Distributed from Mexico to Argentina.

triangulum.

Ph. triangulum R. & J. (= *lycaon* Btlr., *licaon* Ky., *pandorus* Drc.) (98 b a) is very similar, but of a more sepia-brown colour; the subapical costal-marginal spot is not cut off on vein 7, but it extends with a triangular point down to vein 6; the creamy white inner-marginal stripe is almost entirely absent; the distinctly undulated transverse lines are very prominent. Hindwing with a very thick median spot. Mexico to Bolivia. Early stages unknown.

satellitica.

Ph. satellitia Dru. (= *lycaon* Maass.) resembles *triangulum*; of a most variable colouring and marking, so that a number of subspecies have been founded. Recognizable by the double cell-end spot and the fine reddish inner-marginal stripe of the forewing, the anal part of the hindwing mostly showing a red tinge, the trapezoid spot before the centre of the inner margin of the forewing is well defined also inwards. In the nomenclatural form from Jamaica the forewing is suffused with pink, the ♀ is more whitish-grey than continental specimens.

pandorus.

— **pandorus** Hbn. (= *satellitica* Harris, *ampelophaga* Wkr.) (98 C a) is the North American form with a more olive green ground-colour; the inner-marginal area from the base to the trapezoid spot is almost just as dark green as the latter itself, veins 2 and 3 are of a distinct reddish flesh-colour. Disc of hindwing more bluish, the anal portion generally with a pink tint. The light dorsal stripe on the abdomen is scarcely lighter than the

intermedia.

subdorsal spots accompanying it. Canada to Georgia, to the west as far as the Mississippi. — **intermedia** Clark (98 C c) is presumably the most similar to *licaon* and *pandorus*, but without the green tinge the colour being more light grey and light brown. Hindwing basally yellowish-grey, anally with an extremely faint pink tinge.

licaon.

Gulf States, to the west as far as Texas and New Mexico. — **licaon** Cr. (*satellitica* Wkr.) (98 C b) is usually of a duller colouring, less contrastingly coloured, more brownish and never so green as North-American specimens, the basal inner-marginal area much lighter than the trapezoid spot. Hindwing more yellowish-grey, the anal part

analys.

scarcely pink. Mexico to North Brazil and Bolivia. — **analys** R. & J. (= *licaon* Hbn., *satellitica* Burm., *posticatus* Btlr., *lycaon* Burm.) (98 C b) resembles *licaon*, but it has a bright pink anal-angular spot of the hindwing. South

rosea.

Brazil from Espiritu Santo down to the south; Paraguay, Argentina. — **rosea** Closs refers to very light and

excessus.

reddish specimens of the *analys*-race from Brazil (Matto Grosso). — **excessus** Gehlen is the most similar to *analys*. Ground-colour of forewing brownish olive-grey, the whole obliquely cut off apical half is darker than the basal half, with hardly any bands; hindwing almost as in *posticatus*, the dark marginal band very much reduced, the

posticatus.

anal spots continued as a line. From Matto Grosso. — **posticatus** Grt. (= *satellitica* Luc., *lycaon* Grt., *licaon* Ottol.) (98 C b) is somewhat similar to the form *analys*, but the whole postdiscal area of the forewing is distinctly silvery grey like the interior border-line of the trapezoid spot. The dark margin of the hindwing is almost entirely absent, the small black subanal spots are continued as a line almost to the costal margin. Cuba;

cinnamomea.

Bahamas, Florida. — **cinnamomea** Closs is a form of the race *posticatus* suffused with a reddish-brown cinnamon-colour with an indistinct marking. From Cuba, Guantanamo. — Larva green with 5 or 6 lateral oblique spots and fine black dots, especially on the 4th segment. It turns brown shortly before the metamorphosis. It lives on Vitis and Ampelopsis.

macasensis.

Ph. macasensis Clark resembles *satellitica* and *licaon* (98 C b), but it is of a darker colouring and marking; forewing without any white or pink colour along the veins 2 and 3; ground-colour light yellowish with dark brown markings; the dark rhombic area in the centre of the inner margin is narrow and almost rectangular, the whole impression of the wing more variegated. Hindwing without any pink at the anal angle. Under surface: the two postdiscal lines are strong, the exterior one is dentate between the veins, 3 dark lines between them in both wings (being absent in *licaon*). Length of forewing: 58 mm. From Macas, Ecuador.

drucei.

Ph. drucei R. & J. (98 F g). This very rare species resembles the form *posticatus* of the preceding species (98 C b), but it is of a deeper olive colour; the light dorsal line on the abdomen is narrower, the lateral spot on the second segment and the subdorsal spot on the third are larger and of a deeper colour. The trapezoid spot at the inner margin of the forewing is triangular, the tip resting on the inner margin, the postdiscal lines are stronger and more oblique; the triangular costal-marginal shadow is indistinct and not continued to the distal margin, but a rusty yellowish shadow extends along vein 2, and the dark anal spot is prolonged to this shadow. Hindwing with a broad pink inner-marginal spot; 3 distinct black lines follow behind the large black inner-marginal spot. Hindwing beneath pink at the inner margin and in the disc, contrary to *satellitica*. Length of forewing: 40 mm. Ecuador.

neuburgeri.

Ph. Neuburgeri R. & J. This species described from 1 ♂ is much darker than all the others. Forewing with an almost falcate apex; the large inner-marginal spot is likewise triangular, and another large black spot before it at the base of the inner margin, two distinct transverse lines between these spots; discal spot absent, the small subapical costal-marginal spot is triangular; a distinct yellowish-white line extends from the lower cell-angle along vein 2 to the margin, vein 3 is also broadly yellowish-white. Hindwing light greenish-grey, the discal spot is a tiny dot, a small light spot at the anal angle, without pink, 2 narrower lines before the broad black submarginal lines. Under surface bright brick-coloured red. Length of forewing: 48 mm. Argentina, probably Tucuman.

elisa.

Ph. elisa Smyth, from Mexico, resembles small specimens of *licaon*. Forewing greyer above, without a stigma, the apex more produced; a black subbasal spot at the inner margin as in *neuburgeri*, the trapezoid spot behind it is basally prolonged on the submedian fold, lighter in the centre; inner margin not pink. Hindwing as in *satellitica*, the dark marginal band is narrow, but united with the dark inner-marginal spot. Guadalajara (Mexico). It is also allied with the following *cissi*.

Ph. cissi *Schauf.* (= *vinii* *Ky.*) (98 C c). Similar to *anchemolus* and *obliquus*. Upper surface more olive *cissi*. brownish, the trapezoid spot at the inner margin almost triangular, not very dark, two distinct zigzag lines in the light space behind it, stigma at the cell-end absent. Base of hindwing light reddish-yellow, extensive: cellular spot absent, the black inner-marginal spot not very large, an indistinct line from its lower anterior end is continued towards the costal margin; the small black anal spots forming a submarginal band extend to the costal margin. Venezuela, Peru, Bolivia.

Ph. obliquus *R. & J.* (= *satellitiae* *Bönnigh.*) (98 C c) looks very much like *anchemolus* above, but it is *obliquus*. easily recognised by the absence of the cell-end spot of the hindwing and by the 3 parallel almost straight lines in the basal area of the forewing. Ground-colour lustrous lilac grey, the dark spots sepia-brown; the trapezoid spot at the inner margin is not sharply defined inwards and extends into the dark basal part. The dark broad marginal band of the hindwing is somewhat lighter grey anally with indistinct lines and extends below the cell like a broad wedge towards the base. From Mexico to Brazil. We figure a large Mexican specimen. The larva, according to BURMEISTER, is brown with a white oblique band on the 10th segment.

Ph. eacus *Cr.* (= *megaeacus* *Hbn.*, *pandorus* *Drc.*) (98 C d). Dark olive brown, the linear markings *ecacus*. distinct and sharply undulate-dentate, but almost extinct in the light longitudinal area which is suffused with pinkish-brown or more grey and extends from the base and between the veins 2 and 3 to the margin. Hindwing greenish yellowish-grey, a black line from the upper distal end of the black inner-marginal spot almost to the costal margin, the space behind it not shaded black. — Larva light green with 6 light yellow oblique stripes bordered with red above; it lives on a *Jussieua* (*Onagraceae*). Ecuador, Guiana, and to the south as far as Sa. Catharina.

Ph. adamsi *R. & J.* (98 C d). A small species easily discernible by the almost quite pink hindwings, *adamsi*. Forewing brownish cinnamon-coloured, strewn with brown, with fine linear markings as in the following *translineatus* (98 C d) and a large black basal spot; the trapezoid spot at the inner margin is reduced to a small black triangle, the dark costal-marginal shadows are almost quite absent. Hindwing black at the base, lighter lilac-pink in the disc than at the carmine margin; at the anal angle there is a black ring filled with pink, from which a submarginal band extends towards the costal margin. Length of forewing: 40 mm. Venezuela.

Ph. translineatus *Stgr.* (98 C d). Forewing fawn with fine darker linear markings, a dark spot at the *translineatus*. inner margin in the centre, and two small ones before the anal angle. Hindwing without any pink tinge, with a black basal spot and a dark marginal band, a light reddish-brown stripe at the inner margin. Abdomen with dark triangular subdorsal spots on the two middle segments. Only known from Sa. Catharina. — *extinctus* *extinctus*. *Gehlen*, described according to a ♀ from Ecuador (?), lacks both the dark spot in the centre of the inner margin and the two small anal-angular spots; the dark apical area is also distally lighter again.

Ph. achemon *Dru.* (= *crantor* *Cr.*) (98 C e). This beautiful species has light brown forewings with fine *achemon*. lighter veins in the postdiscal area and very indistinct linear markings, a large deep velvety brown trapezoid spot in the centre of the inner margin, the interior and exterior sides of which are somewhat concave, an irregular subanal spot and a triangular subapical spot. Hindwing pink, brownish-grey at the margin, with a curved subterminal band composed of small black spots, and a dark red spot tinged with brownish-grey above the interior angle. North America to Mexico. — *trigon* *Gehlen* resembles the following *typhon* by the subapical *trigon*. spot being longer triangular and continued analwards as a feeble line, the spot being red-brown and distally bordered with whitish-grey. Ground-colour more grey and lighter. Hindwing more reddish-brown, the subterminal band of black spots is distinctly prominent. North Mexico, according to JORDAN also in Arizona. — The larva is green or red-brown with 6 white lateral spots; on *Vitis* and *Ampelopsis*.

Ph. typhon *Klug* (98 C e) is somewhat similar to *achemon*, but much larger, of a greyer ground-colour, *typhon*. the lines and spots much more distinct and deep brownish-black, the spots much larger, especially the subapical spot the apex of which is connected with the triangular anal spot by a line on the inner side of which there is a parallel line; the space behind and below the cell is darkened, the veins 2—4 especially distinct and broad yellowish-white. Hindwing similar as in *achemon*, but the red colour is duller, basally brightened up into yellowish-white, the black submarginal band is coherent, distally dentate, accompanied in the anal half by a parallel double line in front of which there are 2 violettish-blue spots. Larva unknown. Only from Mexico.

Ph. strenua *Mén.* (= *mirificatus* *Grt.*, *domingonis* *Rothsch.*) resembles *Ph. satellitia posticatus* and also *strenua*. the following *vitis*, the forewing exhibiting a light subbasal and postdiscal band, the discal band being divided, but the light longitudinal band of *vitis* only indicated basally; marginal area as in *posticatus*. Hindwing as in *vitis*, but with a narrower submarginal band and a less distinct black median band. Haiti and Cuba.

Ph. vitis *L.* (= *fasciatus* *Grt.*, *hornbeckiana* *Harris*, *linnei* *Grt. & R.*) (98 D a). This well-known beautiful *vitis*. species with the light longitudinal band parted by two transverse bands, on the forewing, the hindwing being pink only at the inner margin, is widely distributed in the whole neotropical region and the West Indies and may migrate up to New England. The light bands of the wings are slightly tinged with reddish-yellow in the nomenclatural form, the 3 light vein-stripes in the postdiscal area are clear and distinct. In the whole neotropical

- pallida*. region excepting Jamaica. — **pallida** Closs shows the light markings of the wings still wider and with a reddish tint. From Brazil, Blumenau. — **hesperidum** Ky. is the race from Jamaica, in which the markings of the forewing are of a purer white, moreover mostly only the veins 2 and 3 are striped white, 4 remains more or less darkened.
- fuscatus*. Under surface claret-coloured. — In **fuscatus** R. & J. the light markings are suffused with brown, therefore less contrasting with the olive green markings; the subbasal band is not distinctly bordered with white, the brown line in the grey oblique band is indistinct, the marginal band broader, not bordered with white. Sa. Lucia, Grenada, St. Vincent. — Larva light bluish-green, lighter on the dorsum, or reddish claret-coloured, brown or olive with 5 white oblique spots very finely bordered with black, more or less granulated white. On vine.
- fasciatus*. **P. fasciatus** Sulz. (= jussieuae Hbn., strigilis Vogel, vitis Dru.) (98 D a). Very similar to *vitis*, but at once discernible by the hindwing being carmine also at the distal margin. The antemedian band of the forewing is rudimentary, the discal spot plain, not divided. The hindwing lacks the black median band, but it has a very broad black subterminal band. — Larva very different, green, yellow, or brown, with numerous black transverse lines and with 7 white or yellow oblique stripes. It lives on *Jussieu* (Onagraceae). In the whole neotropical region, to the south as far as Patagonia, migrating to the north as far as New England.
- phorbas*. **Ph. phorbas** Cr. (= pandion Stoll) (98 D b) and the following *capronnieri* are distinguished by orange hindwings. Forewing deep olive green with darker green markings, 2 lines similarly convergent to the inner margin as in *labruscae*, the exterior one cut by an oblique line extending from the centre of the costal margin to the end of vein 3 on the distal margin; apex parted by a straight line which is continued to the inner margin in a thrice broken line; some of the lines are bordered with silvery bluish-grey. Hindwing with a marginal band and a notched median line. From Venezuela and Surinam to Para; Trinidad.
- capronnieri*. **Ph. capronnieri** Bsd. (98 D b) is somewhat like *phorbas* in the scheme of markings, but the ground-colour is light fawn, greenish light grey behind the notched subterminal line; a basal inner-marginal spot, the broad distal border of the antemedian line as well as that of the distal oblique line to the margin on vein 3 are olive green in a broad triangular shape; a distinct discal spot at the cell-end. Hindwing orange with a blackish-brown marginal band and a broad median band from the anal angle to the costal margin. Surinam; Venezuela; Amazons; Ecuador.
- labruscae*. **Ph. labruscae** L. (= clotho F.) (98 D c) is a universally known beautiful green species with 2 lines convergent towards the inner margin and enclosing a somewhat darker median area. Hindwing blue, spotted black, pale yellowish at the inner margin and anal angle, marked with red stripes. — The young larva is green or brown, with a pink horn, in the adult stage brownish, without a horn, with thickened 3rd and 4th segments, the latter with an ocellus, the young larva with 6 green oval lateral spots, the adult with a blue, dentately bordered dorsal band terminating on the 11th segment in an ocellus instead of the horn. On *Vitis* and *Ampelopsis*. Very widely distributed from Canada to Patagonia, but only as a migratory insect in the northernmost and southernmost districts.

Tribe: *Nephelicae*.

51. Genus: **Ampeloecca** R. & J.

The genus contains only 2 medium-sized, moderately slender *Sphingidae* from North America. Haed with a rounded tuft, eyes ciliated; antenna rather long and slender with a short terminal segment; pulvillus and paronychium present. Wings entirely margined. Costal margin of hindwing not produced.

Type: *A. versicolor* Harris.

- versicolor*. **A. versicolor** Harris (98 D c). Olive green with 2 whitish tripartite antemedian and postmedian lines, the latter only tripartite below the costal margin, and with an oblique dark green median band and a small discal dot. Hindwing light reddish cinnamon. Easily recognizable beneath by the very bright yellow postmedian colouring in both wings. — ab. **lutescens** Clark is yellow on the forewing, hindwing lemon-coloured, slightly darkened at the anal angle. 1 ♂ from Long Island. — Larva green or brown with light subdorsal lines as far as the 4th segment and 7 light oblique bands behind them; horn long with a black dorsal stripe. On *Cephalanthus*, *Nesaea*, *Hydrangea*. Canada to Maryland; to the west as far as the Mississippi basin.
- myron*. **A. myron** Cr. (98 D b). Ground-colour olive grey, mostly with a feeble reddish tinge and olive green antemedian and postmedian transverse bands, and a thick discal dot. The nomenclatural form is distinctly marked and of contrasting colours. — **cnotus** Hbn. (= pampinatrix Abb. & Sm.) is the form from Florida to Mexico with a much duller and more monotonous colouring, more brownish. — subsp. **texana** Clark, from the Gulf States as far as Texas and New Mexico, is somewhat larger and of a much lighter colouring, light brown, with darker brown markings, but less contrasting than the nomenclatural form. — ab. **lutescens** Clark is yellowish on the forewing, lemon-coloured on the hindwing. — Larva green or brown with light subdorsal lines extending to the horn and oblique lateral stripes, the dorsum with light spots centred with dark brown. On vine.

52. Genus: **Darapsa** Wkr.

This genus containing but one species is separated from the preceding *Ampeloeca* by spined tibiae. Veins 6 and 7 of hindwing are stalked. Otherwise very much like the two preceding species in the exterior.

D. pholus Cr. (= *azaleae* Abb. & Sm., *chlorinda* Martyn, *choerilus* Cr.) (98 D d). Light reddish-brown *pholus*. with a faint lilac pink shine and a darker brown distal half; in which there is an irregularly undulated subterminal line; apex and the upper three fourths of the margin of the light ground-colour. Hindwing cinnamon-red. The form — **flavescens** Closs, from Canada, has yellowish-grey forewings and reddish-yellow hindwings. — *flavescens*. **brodiei** Clark, from Manitoba, Ottawa and New Scotland, the larva of which lives on *Viburnum opulus ameri-* *brodiei*. *canum*, is somewhat smaller than typical *pholus*, more distinctly marked, therefore more variegated, the lines in the postmedian area are less distinct, the median line often absent. Apex more produced, the discal margin more concave in the upper half, the lower more convex. — The light lines on the thorax are more distinct. — The larva resembles that of *A. myron*, but the dark-centred dorsal spots are absent, and the light subdorsal line extends to the head, whilst in *myron* it begins only at the 4th segment. It lives on *Ampelopsis* and *Vitis*.

53. Genus: **Gurelea** Ky.

It is a most remarkable fact that two Mexican representatives have been discovered of this otherwise Indo-Australian genus (cf. Vol. X, p. 554 and Vol. II, p. 254), one representative of which, *masuriensis* Bltr., extends into the palaearctic region. Small Sphingids with dentate distal margins; eyes ciliated, head with a parted tuft with 2 ridges. Antennae short, filiform. Tibiae spined.

Type: *G. hyas* Wkr.

G. muelleri Clark. Antennae brown above, grey below, palpi grey, strewn with brown, like the body; *muelleri*. ventrum grey, the segments dark red beneath, strewn with yellow, one white dot on each side of these 3 segments. Forewing above bluish-grey, marked darker than in *sonorensis* Clark, the contrasts between light and darker more distinct than there; stigma very narrow, crescentiform, convex basally; a dark dentate band in the centre of the wing, the tip on vein 4. Hindwing bright yellow with a black marginal band, narrower than in *sonorensis*. Anal angle grey, enclosing a black line. Length of forewing: 21 mm. Guerrero.

G. sonorensis Clark (98 D b). Similar to *muelleri*, forewing light brown, the oblique median line not *sonorensis*. dentate on 4; some dentate lines near the anal angle. Hindwing yellow, the brown distal margin not sharply defined, the whitish anal spot enclosing a dark line. Sonora, taken in August.

54. Genus: **Sphecodina** Blch.

This very peculiar genus containing only 2 species shows a peculiar range, one species occurring in Eastern Asia (*caudata* Brem. & Grey, Vol. II, p. 252 and pl. 39 e), the second just at the opposite coast of America, only in the Eastern States. Abdomen flattened, with lateral hair-tufts and a tripartite anal tuft in the ♂. Shape of wings narrow, distal margin angularly dentate.

Type: *S. abbotti* Swains.

S. abbotti Swains. (98 D c). This quite unmistakable species exhibits violettish-black forewings with *abbotti*. light brownish-grey oblique lines in the distal area, with very long black sagittal streaks. Basal part of hindwing light lemon-coloured with a broad black distal part. — Larva green or brown with large green spots above and on the sides. It lives on *Vitis* and *Ampelopsis*. Canada to Georgia and the Mississippi.

55. Genus: **Deidamia** Clem.

The only species resembles species of *Hemeroplanes* in its exterior. Head tufted, palpi small, coarsely haired, eyes ciliated, antennae long filiform. Abdomen with a small triangular anal tuft. Tibiae spineless. Pulvillus and paronychium present. Distal margin of forewing strongly and irregularly dentate.

D. inscriptum Harr. (98 D c). This pretty light grey species marked with dark brown is much bred. *inscriptum*. Forewing light violettish-grey with a brown curved antemedian line with a darkened brown distal part which remains light grey above vein 6, a white triangular spot below the apex, and small dark brown spots before it. Hindwing cinnamon-red with a dark brown submarginal line and white fringe. — Larva green with light subdorsal lines terminating into the granulated horn. On *Vitis* and *Ampelopsis*. Canada to Virginia, to the west as far as the Mississippi.

56. Genus: **Arctonotus** Bsd.

Three species remarkably similar to *Geometridae* and very closely allied to the following two genera *Euproserpinus* and *Proserpinus*, but separated by the peculiar woolly hair. Antennae thinner basally and apically, strongly compressed. Palpi short; tibiae with long spines, a short apical spine at the end of the anterior tibia. Pulvillus absent, paronychium rudimentary.

Type: *A. lucidus* Bsd.

lucidus. **A. lucidus** Bsd. (98 D d). This peculiar and rare species has a dark olive green body and a similarly coloured basal and median band of the forewing, the latter band not reaching to the costal margin, because a more greyish antemedian band is united here with a similar postmedian band, so that the dark median band ends rounded here; the two said bands are finely edged with whitish, the posterior one is traversed by a yellowish-white stripe on vein 4; marginal area broad light olive grey. Hindwing reddish cinnamon, darker towards the margin, with a blackish-brown marginal band and broad light fringe. Early stages unknown. The imagines fly in early spring, from January to March, and come to the lantern late at night. From Washington to Arizona.

terlooi. **A. terlooi** Edw. is very similar to *lucidus* from which it only differs in claret-coloured hindwings and the absence of the green basal band on the forewing. Apparently extremely rare, hitherto only known from Mazatlan (Mexico).

vega. **A. vega** Dyar is only known to me from the very insufficient description in Dyar's List of N. A. Lep.: forewing as in *terlooi*, but with a dark green basal band, thus probably as in *lucidus*. Hindwing as in *P. juanita*, of a bright orange with a sharply defined black marginal band. Expanse of wings: 54 mm. New Mexico.

57. Genus: **Amphion** Hbn.

The porrect palpi end taperingly; eyes ciliated; antenna filiform, slightly thickened behind the middle with a long thin hook at the end. Anterior tibiae finely spined; paronychium present. The abdomen ends in a tripartite anal tuft in the ♂, more truncately in the ♀. Distal margin of forewing with a round convexity in the middle, concave below and above it. Only 1 diurnal species:

nessus. **A. nessus** Cr. (= oecypete Houttuyn) (98 D d). Forewing brown with a blackish-brown narrow oblique band in the middle, with fine light transverse lines before and behind it, the posterior one angular in the centre and crossed here by a dark blotch, similar spots subapically and before the anal angle. Hindwing rusty red, yellowish-white at the costal margin, with a blackish-brown marginal band and yellowish-white fringe crossed by dark. Abdomen with a yellowish-white belt at the distal edge of the 4th segment, ventrum with 2 yellow belts on the 5th and 6th segments. Southern specimens are coloured darker than northern ones. — *floridensis* Clark is a still darker and more monotonous summer breed from Florida with a narrower band of the hindwing. — Larva brown, with darker dorsal spots and oblique brown lateral bands, the 1st to 3rd segments with dark brown dorsal and subdorsal lines; horn pointed and short. It lives on *Epilobium*, *Vitis* and *Ampelopsis*. Atlantic States from Canada to Florida, to the west as far as the Mississippi.

58. Genus: **Proserpinus** Hbn.

Very similar to *Amphion*; distinguished by the more clubby antenna with a short, suddenly thinned terminal hook, more strongly spined tibiae, the anterior tibia with an apical spine, and an obliquely placed cross-vein on the hindwing, whilst it is rectangular to the two cell-veins in *Amphion*. The type of the genus: *P. proserpina* Pall. is palaearctic, America has 4 similar species in its northern part.

gaurae. **P. gaurae** Abb. & Sm. (= *circae* Edw.) (98 D d) has narrow slender wings and is light olive green with an oblique dark median band and a likewise darkened marginal area; apex crossed by light. Hindwing orange-red, more brownish basally with a dark red-brown marginal band. Ventral side and base of hindwing beneath likewise cinnamon-red. — Larva green with red interrupted subdorsal lines and similar oblique lateral bands and sublateral spots. Horn short and pointed, black. It lives on *Gaura biennis*. Georgia to Texas.

juanita. **P. juanita** Stkr. (= *gaurae* Clem.) (98 D d) is very similar to *gaurae*, but larger and of a much brighter green and orange colour, with broader wings, the median band broader. Hindwings with a sharply defined black marginal band. The basal area of the forewing beneath is orange, whilst that of the hindwing is olive green like the ventral side. Texas, Colorado. — *oslari* R. & J. is the lighter subspecies from Arizona, the green

colour of the forewing as well as the orange colour of the hindwing is paler; stigma of forewing smaller, fringe more distinctly speckled. — Larva red with two whitish lateral lines, the upper one of which is traversed by oblique stripes. Likewise on *Gaura*.

P. clarkiae *Bsd.* (= *victoria* *Grt.*) (98 D e) resembles *gaurae* in colouring and marking, but it has less *clarkiae*. long wings with a more convex distal margin, especially of the hindwing, and the anal angle is not produced; median band of forewing broader, more rounded distally and not so oblique. Hindwing lighter yellow than in *juanita*. The whole lepidopteron looks more Bombycid-like by the stouter abdomen, like the species of *Haemorrhagia*. — Larva not described, but it is reported to live on *Clarkia*. In the Pacific States: British Columbia to California.

P. flavofasciata *Wkr.* (98 D e) differs from the other species in the black body on which only the head *flavo-* and thorax above as well as the apex of the abdomen are straw-coloured. Forewing olive brown with a scantily *fasciata*. grey-scaled postdiscal band; hindwing yellow with a black basal and marginal band. Eastern Canada and New England. — **ulalume** *Stkr.* (98 D e) has almost entirely black hindwings in the typical form with a traceable *ulalume*. triangular yellowish-grey postdiscal band which becomes broader and more yellow in transitional specimens, but never reaches the inner margin as in the typical form. Oregon, British Columbia. — **rachel** *Bruce*, founded *rachel*. upon one specimen, seems to be an intermediary form with a brighter and broader band on the hindwing than in *ulalume*. The larva is said to resemble that of *Sph. abbotti* and to live on *Epilobium*. Colorado.

59. Genus: **Euproserpinus** *Grt. & R.*

Very similar to the preceding genus, only separated by the absence of the paronychium and pulvillus. Moreover, the terminal hook of the antenna is somewhat more suddenly bent down and thinner. Only 2 species:

Type: *E. phaeton* *Grt. & R.*

E. phaeton *Grt. & R.* (= *erato* *Bsd.*) (98 D e) to a certain degree resembles *P. flavofasciata* externally, but the under surface and the hindwing are white. Forewing scantily scaled olive grey, more densely scaled in the basal part and marginal area, with a discal streak at the cell-end and a postmedian transverse line indicated by vein-dots. Hindwing with an equably broad black marginal band. Abdomen with yellowish-white lateral tufts. South California.

E. euterpe *Edw.* has similar whitish lateral tufts on the abdomen. Ground-colour more brown, not *euterpe*. blackish, the marginal band less contrasting and cut in deeper than in *phaeton*, and the marginal band of the hindwing is convex in the middle. Antennae scaled white, otherwise very similar to *phaeton*. It appears to be extremely rare. Likewise from South California.

Subfamily: *Choerocampinae*.

60. Genus: **Xylophanes** *Hbn.*

This naturally composed genus contains an immense number of very slender, mostly rather large Sphingid species with narrow pointed forewings and a long, pointedly ending abdomen. Antenna slender, not thickening towards the end, with a long thin terminal hook. Eyes mostly ciliated. Tibial spurs unequally long, the exterior ones short; pulvillus and paronychium present. The larvae are thinner in front, generally with ocelli on the thoracic segments; they mostly live on Rubiaceae.

Type: *H. anubus* *Hbn.*

X. depuiseti *Bsd.* (98 D e). Olive green; abdomen with two rows of very faint brown dorsal dots on *depuiseti*. each side of which there is a row of light golden dots. Forewing with two antemedian and 3 postmedian oblique transverse lines, the 2nd postmedian line being feeble, the 3rd bearing fine vein-dots; a black stigma at the cell-end; the feeble subterminal line ends at the anal angle. Hindwing with a blackish median and marginal band and white-speckled veins. Brazil (Espírito Santo, Sa. Catharina).

X. adalia *Drc.* (98 D f) is very similar to the preceding species, but the lines of the forewing are stronger, *adalia*. and a black subterminal patch is between the veins 4 and 5; the fringe of the forewing are here also distinctly speckled white as far as the apex, in *depuiseti* only a little near the anal angle. The apex of the forewing is not so sharply falcately produced. Under surface distinctly golden yellow. Panama (Chiriqui).

X. ploetzi *Mschlr.* (= *drucei* *Rothsch.*) (98 D f). Likewise very similar, but the subterminal black spot *ploetzi*. on the forewing is absent, the stigma at the apex of the cell is white and the fringe of the forewing speckled white between vein 4 and the anal angle; the transverse bands are as strong as in *adalia*, excepting the most exterior one. Under surface yellowish green; abdomen with a fine dark median line. Surinam; British Guiana.

- pluto.* **X. pluto** *F.* (= *boerhaviae F.*, *croesus Dalm.*, *eson Wkr.*, *thorates Hbn.*) (98 D f) is easily recognizable by the orange hindwing with a black base and a blackish-brown marginal band (no other species has orange hindwings). Forewing olive green with a violettish-grey median band and a crescentiform marginal spot in the upper half of the distal margin. Abdomen with golden spots. — The larva (a dark form and a light one) shows a large ocellus on the 4th segment. It lives on *Erythroxylon coca*. Mexico and Florida as far as Southern Brazil; Antilles and Bahamas.
- tyndarus.* **X. tyndarus** *Bsd.* (98 D f). This rare and beautiful species is light green above with 3 faint antemedian lines and 4 postmedian ones, the first of them very strong, distally shaded with dark; a dark antemarginal patch before the centre of the margin. Hindwing black with a green band. Mexico to Southern Brazil. — **marginalis** *Clark* (98 D f) is smaller with shorter wings, the green colour more yellowish; the 3 antemedian lines are very indistinct, the first postdiscal one distally with a scarcely darker shadow which is not gradually brightened distally, but uniformly and distinctly defined. The green colour on the hindwing is much more extensive, so that only a narrow blackish marginal band remains. Rio Grande do Sul.
- pistacina.* **X. pistacina** *Bsd.* (= *diogenes Maass.*, *jocaste Drc.*) (98 D g) is somewhat like *tyndarus*, but duller olive greenish with a feeble reddish-yellowish shine, the 3rd and 4th postdiscal lines distinctly undulate-dentate, intensified by vein-dots; an oblique darker patch before the centre of the margin, distally bordered by the continuation of the distinct dark apical line. Hindwing extensively blackish, the light green band darkened brownish. Mexico to South Brazil and Paraguay. — **reussi** *Closs* (98 D g) is a loamy brown form with a dark brown postdiscal band and a dark grey, darker speckled marginal area. Hindwing dark brown with a yellowish band. Under surface yellow, speckled brown. Mr. GEHLEN had the kindness to lend the only type from Brazil (?) for having it figured.
- mossi.* **X. mossi** *Clark* (98 D g) is a beautiful large species resembling the following *rufescens*. Forewing reddish loamy brown, yellowish-white and black at the base of the inner margin; a tiny black dot at the cell-end and two feeble blackish postdiscal lines, the distal subterminal line intensified by black vein-dots; a small blackish spot 7 mm before the apex at the costal margin. Hindwing black with a feeble yellowish-white submarginal band, and a yellowish-white spot at the anal angle, continued at the inner margin almost to the base. — The larva is bright red-brown, with black subdorsal lines on the 5 first segments and yellowish-white lateral lines ending on the 4th segment in the yellowish ocellus which is edged with black; the 6th to 10th segments exhibit bright green lateral spots, and a yellowish-white oblique line extends from the 10th segment to the very short and thin small horn. Another form is greyish-green, brownish on the dorsum, with 5 yellowish lateral stripes. It lives on *Pagamea guianensis* (Rubiacea) and is very frequently set with Diptera. Pará.
- rufescens.* **X. rufescens** *Rothsch.* (98 D g). The reddish-yellow ground of the forewing is densely dusted and strewn with rust-brown, very similarly marked as the preceding species. Hindwing black, with a yellowish-white submarginal band not reaching the costal margin and widened towards the inner margin, another yellowish-white spot behind it at the anal angle. Both wings beneath rusty reddish. British Guiana, Amazons, Peru.
- irrorata.* **X. irrorata** *Grt.* (98 D g) is a monotonously dark cinnamon-brown species with but one darker, almost straight postdiscal line which is finely bordered with light grey inside; tegulae and head as far as the apex of the palpus outside bordered with white. Hindwing blackish-brown, lighter olive basally. — Larva not described: it is said to live on *Psychotria*. Cuba, Bahamas, Haiti.
- gundlachi.* **X. gundlachi** *H.-Sch.* (98 E a) is a smaller, beautifully green species with but one postdiscal transverse line as in *irrorata*, terminating at the inner margin in a brown spot; costal margin and fringe reddish, the latter analwards brownish intermixed with some white scales; the small stigma at the cell-end is black with a white centre. Hindwing blackish-brown, somewhat lighter mottled with yellowish-white fringe. Cuba.
- rhodocera.* **X. rhodocera** *Wkr.* (98 E a). Head and tegulae olive brown, the rest of the body and the forewing more violet-brown, the forewing similarly marked as in *porcus*, but without the subterminal row of vein-dots, the distal margin much more convex than in *porcus*; a darker, slightly curved postdiscal line; an olive brown spot is behind the cellular stigma, another spot occasionally also in the centre of the cell; the anal area at the margin is usually dusted with a darker brown. Hindwing black, light yellowish-white in the anal half of the margin. Abdomen with a large black lateral spot at the base. Antennae scaled pink. Haiti.
- porcus.* **H. porcus** *Hb.* Wings falcately produced at the apex. Forewing olive brown, prothorax somewhat more olive greenish, feebly marked; the nomenclatural form has a distinct black stigma, an olive green spot behind it, then an indistinct curved transverse line, a submarginal row of vein-dots. Hindwing blackish-brown lighter brownish-yellow anally. Only from Cuba. — **continentalis** *R. & J.* (98 E a) is the common continental form with much less distinct markings; stigma much smaller, the olive spot behind it scarcely traceable, but the subterminal vein-dots somewhat better marked. From Mexico to Sa. Catharina. — Larva green, with yellowish-white subdorsal lines on the thoracal segments, blue ocelli on the 5th segment, the other segments

with 7 yellow oblique stripes bordered with bluish-green and extending across 2 segments each; horn reddish. It lives on *Palicourea grandifolia* (Rubiacea), the Cuban form, according to GUNDLACH, on *Hamelia patens*.

X. hannemanni *Closs* (98 E a) may be only a form of *porcus* with somewhat differently shaped wings, *hannemanni*. a more falcate apex and a produced anal angle. Forewing reddish olive brown without markings, tegulae not bordered with white; but with red-brown; the forewing only exhibits the small stigma and a submarginal row of dots, the marginal area is dusted with grey. Hindwing with traces of a reddish transverse band. Described according to 1 ♂ from Mexico.

X. schausi *Rothsch.* (= *arpi* *Schs.*, spec. *B. Bönningh.*) (98 E a) is larger than *porcus*; tegulae and head *schausi*. as far as the tips of the palpi laterally bordered with white; distal margin of forewing much more convex than in *porcus*; the 4 postdiscal lines are undulate-dentate, very feeble, the last marked by vein-dots; a small, distinct, dark apical crescentiform spot, from which a feeble line is continued to the dark olive green submarginal spot above the centre of the margin. Hindwing similar as in *mossi*, the light band dusted with olive. Brazil (Rio de Janeiro, Espiritu Santo). — **serenus** *R. & J.* shows but very faint traces of the olive green submarginal spot of *serenus*. the forewing. From the Amazons (Rio Madeira) and Venezuela.

X. germen *Schs.* (98 E b) is near *schausi* and also *pistacina*, but not green as the latter, but brown. *germen*. Forewing with two indistinct antemedian lines, the postdiscal lines undulate-dentate, but not very prominent. Hindwing darker brown, lighter anally, with white fringe speckled dark on the veins; tegulae bordered with reddish towards the head; antennae reddish, laterally black. Margin of forewing feebly dentate, with a pointed apex. Mexico, Colombia, Venezuela, Ecuador.

X. hojeda *Gehlen* (98 E b) has broader forewings than *germen*; body and forewing from sepia to olive *hojeda*. greyish brown. Apex of forewing pointedly produced; marking as in *germen*, but the lines are more distinct, straighter and not so strongly notched, the distal one is only marked by vein-dots; discal area broader, stigma larger. A lustrous light reddish-brown submarginal spot between the veins 4 and 5. Hindwing as in *germen*. but the distal margin is not speckled on the ends of the veins. West Colombia.

X. brevis *Clark* (98 E b) has shorter wings than *germen*, with relatively broader forewings. More *brevis*. contrastingly marked, the median undulate double line distinct; another double line proceeds from the inner margin 1 mm before the anal angle and reaches the first double line midway between the inner margin and costal margin, so that a triangle is produced, the base of which is at the inner margin. Length of forewing: 27 mm. Described from an unknown habitat.

X. juanita *R. & J.* (= *mexicana* *Schs.*) resembles *brevis*; abdomen with two dorsal rows of dark dots; *juanita*. tegulae anteriorly bordered with reddish as in *germen*. Forewing with traces of one or two antemedian lines, 4 postmedian lines, the two first being undulate-dentate, the 4th intensified by vein-dots, a dark spot behind it on vein 5, an indistinct line in the apex. Hindwing darker brown than forewing, lighter anally, the white fringe with tiny dark spots on the veins. Vera Cruz (Mexico).

X. fusimacula *Fldr.* (98 E b). Head, collar and tegulae green, mesothorax grey, abdomen reddish-brown with 3 dark longitudinal lines. Forewing green, with black undulate-dentate lines and reddish-brown spots at the cell-end, in an oblong-quadrangular spot before the centre of the inner margin, between the 2nd and 3rd postdiscal lines and in the antemarginal area, especially broad in the anal half. Hindwing black with a reddish median band and greenish margin. Brazil and Peru. — **niepelti** *Gehlen* has somewhat broader wings *niepelti*. and a less produced apex; the reddish-brown areas are mouse-coloured here, the light inner-marginal spot is triangular and much smaller, the light cellular spot surrounding the stigma is much smaller, too. Band of hindwing more distinct and lighter anally. West Colombia.

X. zurcheri *Drc.* (98 E b) resembles *fusimacula*, but the distal margin of the wings is distinctly dentate *zurcheri*. as in the following *undata*, but the ground-colour is a brighter green here and the markings are rather like those of *fusimacula*. Hindwing with a distinct yellow band through the centre. A rare species from Costa Rica.

X. undata *R. & J.* (= *irrorata* *Rothsch.*) (98 E c). Margin of forewing and of hindwing distinctly dentate. *undata*. Forewing greyish-green, reddish ash-grey in the whole submarginal area and in the basal inner-marginal area; undulate lines similar as in *zurcheri*, but rather indistinct, somewhat darker olive-brown than the ground-colour; the most distinct line is the submarginal line intensified by vein-dots, with a roundish black spot before the anal angle at the inner margin. Hindwing blackish-brown with a reddish olive postdiscal band. Peru (Chuchuras).

X. rhodina *R. & J.* Margins of wings not dentate; forewing greenish olive with a black stigma; basal *rhodina*. area violettish-grey with a reddish tint, of the same colour is the subterminal area near the inner margin; lines similar as in *undata*, but still more indistinct and less dentate, the submarginal line scarcely stronger than the others. Hindwing somewhat greyer than the forewing, with an indistinct lighter reddish postdiscal band and a brown extinct line in it. Under surface rusty red. Very rare and hitherto only known from Panama (Chiriqui).

godmani **X. godmani** Drc. (98 E c) is near *rhodina*, forewing more falcately produced at the apex, the distal margins dentate as in *undata*, the transverse lines still more indistinct than in *undata*, the first of the postdiscal lines removed farther basad at the inner margin, the anal angle itself much more produced. Hindwing narrower, the light anal spot parted by a transverse line which is continued for a little distance. The chocolate-brown submarginal band beneath is broadly confluent with the similarly coloured basal part, whereas it is separated from it in *rhodina*. Panama, Chiriqui.

falco. **X. falco** Wkr. (= *fugax* Bsd., *mexicana* Ersch., *talco* Mschlr.) (98 E c) is a very peculiar species owing to the characteristic wing-contours. Apex falcate, anal angle very much produced downwards. Forewing brownish yellowish-grey, costal margin and distal area light ash-grey; two very indistinct and oblique antemedian lines; the space between the 3 first postdiscal lines is filled with dark ash-grey; besides three delicate grey parallel lines in the marginal area. Hindwing yellowish-grey, the costal-marginal part yellowish-white, basal part blackened, containing 2 or 3 partly spotted transverse lines; the margin is dove-coloured behind the black submarginal band. Fringe white, traversed by black. Mexico to Guatemala and Honduras.

xylobotes. **X. xylobotes** Burm. (= *xylobates* Ky., *ceratomioides* Drc.) (98 E c). This species and the 3 next are very near to each other. Lighter than the very common *ceratomioides* Grt. & R., the dorsal lines on the abdomen always coherent; the 3 dark costal-marginal spots in the middle and before the apex are very small and indistinct; the subbasal shadowy line extends along the lower cell-margin to the lower cell-angle; the postdiscal lines are not dentate; distal margin not undulate, without the small dark internerval spots. Hindwing similarly coloured with a blackish median and marginal band and a black inner-marginal area interrupted by light. — Larva green with an interrupted dorsal line and darker green subdorsal lines forming the upper border of a white oblique stripe between the 10th segment and the horn; traces of 5 darker green oblique bands, a small white ocellus on the 4th segment. Peru; Argentina; South Brazil.

media. **X. media** R. & J. (98 E d) is extremely similar to *ceratomioides*, recognizable by the 3 fine dorsal lines on the abdomen being convergent towards the proximal margin of each segment; the 4th postdiscal line is also very distinct in the light area of the wing and undulate-dentate. The light parts of the hindwing are smoky brownish, the black median band narrow and distinct. Under surface uniformly reddish cinnamon. Venezuela and Peru.

ceratomioides. **X. ceratomioides** Grt. & R. (= *anubus* Wkr., *capreolus* Schauf., *minos* Mén., *xylobates* Bönningh.) (98 E d) is the most intensely coloured and marked species, the 3 dorsal lines on the abdomen parallel, forming black spots at the distal margin of the segments. The subbasal shadowy line on the forewing only extends a little beyond the origin of vein 2; all the 5 postdiscal lines are distinct, the most distal one is dentate; the proximal one of the two subapical costal-marginal spots is very large and black. The space between the postdiscal lines on the under surface is distinctly rusty red. — Larva brown, darker dorsally, irrorated darker laterally; subdorsal line black, a small light brown ocellus on the 4th segment. Mexico to South Brazil.

guianensis. **X. guianensis** Rothsch. (98 E d). Distal margin deeply concave at the spaces between the veins, otherwise very much like *ceratomioides*, the light antemedian area tapering towards the inner margin where it ends pointed; the exterior postdiscal lines somewhat dentate only above the inner margin and less curved, distinct also in the light subterminal part which is darker than in *ceratomioides* and not so sharply defined. The black median band of the hindwing is broader than the light postdiscal band. British Guiana; Ecuador. — Young larva green, with yellow longitudinal stripes, adult larva brown, darker above with traces of lighter oblique stripes and a light brown ocellus on the 4th segment; horn crenulate like a saw. On *Palicourea grandifolia*.

anubus. **X. anubus** Cr. (= *alcides* Bsd., *miradoris* Bsd., *nitidula* Clem., *laevis* Grt. & R.) (98 E d) is one of the largest species and most variable, mostly yellowish-grey with an olive tint and 7 postdiscal parallel oblique lines, the first and the 4 last being strongest, the submarginal line intensified by black vein-dots. Hindwing black with a light yellowish-grey median band, mostly parted by 3 thick black veins. — ab. **infernalis** Gehlen *infernalis*. has almost quite black hindwings, only the anal area is light. From Sa. Catharina. The species is distributed from Mexico to Southern Brazil. — Young larva green with a red ocellus, adult larva brown with a black ocellus in a fine blue ring, with 7 fine moss-green lateral lines. It lives on *Palicourea* (Rubiaceae).

docilis. **X. docilis** Btlr. (98 E e) may be only a form of *amadis*; abdomen with a distinct median line. Distal margin of forewing straighter than in *amadis*, the oblique line also straighter; a submarginal row of vein-dots, and traces of a dentate light subterminal line. The brown marginal band of the forewing beneath is narrower. Ecuador and Bolivia.

amadis. **X. amadis** Stoll (= *thalassina* Clem.) is a most variable species, forewing varying from olive green to red-brown, with a strong black, slightly curved oblique line to the apex, proximally bordered with yellowish-white; 2 curved antemedian transverse lines, and a more or less distinct shadowy spot behind the small black discal dot; a submarginal row of vein-dots, occasionally connected by feeble arcuate lines. Hindwing blackish with a yellowish-grey median band, which is not interrupted by black in the nomenclatural form from Guiana

and intensely smoked dark. — **meridanus** *R. & J.* is very similar to *X. amadis*, but the band of the hindwing is lighter and interrupted by black on 3 veins. The proximal border of the oblique stripe on the forewing is not so purely white. Venezuela. — **cyrene** *Drc.* (= *drucei* *Ky.*, *epaphus* *Schs.*, *docilis* *Drc.*, *staudingeri* *Rothsch.*) the northern race from Mexico to Colombia has generally less distinct submarginal vein-dots, and the light band on the hindwing is not interrupted on the veins, but of a duller and darker colour and less sharply defined. — In **stuarti** *Rothsch.* the light colour along the oblique line of the forewing is of a purer white and very broad, the light band of the hindwing as in *cyrene*, but more distally removed. Peru. — **goeldi** *R. & J.* is olive green, tegulae bordered with white, the oblique line of the forewing likewise broadly bordered with pure white, still broader apically. The light band of the hindwing is green, triangularly interrupted on the veins. From Para.

X. epaphus *Bsd.* (= *böttgeri* *Rothsch.*) (98 E c) is very similar to *amadis*, especially the form *cyrene*, but of a much more reddish tint, the two antemedian lines much more separated, the oblique line does not extend so obliquely into the apex, but only bends towards it shortly before the costal margin; the postcellular shadowy spot is smaller. Hindwing with a broad reddish median band. Guiana; Peru; Brazil (São Paulo).

X. acrus *R. & J.* is allied with *amadis*. Apex of forewing long and pointedly produced; as in *amadis*, a strong greenish-black line runs from the apex to the basal third of the inner margin and it is bordered inside with light greenish-yellow, 3 fine lines intensified on the veins are before it; costal-marginal area olive green, 2 curved dark antemedian lines do not reach the inner margin; a faded blackish shadowy spot is behind the black stigma; the wing is so densely dusted with dark olive green behind the oblique line, that only a submarginal row of vein-dots is visible, slightly connected by feeble arcuate lines. Hindwing black with a light reddish-yellow band traversed by 2 black veins, notched by 2 other black veins; margin light greenish olive; fringe reddish-yellow with 3 black vein-dots. Length of forewing: 49 mm. Panama (Chiriqui).

X. alegrensis *Closs* (98 E c) is a distinct species according to GEHLEN. Separated from *amadis* by its much smaller size; the reddish-grey forewing lacks the light line, the dark line dividing the wing into two areas is distally bordered by a green wedge-stripe; the shadowy spot behind the apex of the cell is absent. The ground-colour is a velvety reddish-grey, the costal-marginal part is green. The light band of the hindwing is parted by 3 black veins, the costal margin is black. The light edging of the head as well as the black dots on the abdomen are absent. Length of forewing: 36 mm. From Porto Alegre (South Brazil). Mr. GEHLEN had the kindness to put the type at our disposal for having it figured.

X. belti *Drc.* (98 E c). Thorax and forewing dark green, shoulders, sides of head, and palpi brick-red like the under surface. The green ground-colour exhibits scarcely darker transverse lines, between which the ground-colour shows a peculiar bluish silvery grey reflection, particularly in the median area and in a dentate submarginal band. Hindwing black with a proximally dentate yellowish-grey median band which, however, may be also greenish or reddish. Mexico to Panama (Chiriqui).

X. rothschildi *Dogn.* Forewing green with an olive green basal shadow, a small black cellular dot and, distally to it, another olive green shadow; a dark green oblique line extends from the centre of the inner margin to the costal margin close before the apex, the inner margin being reddish-pink before the beginning of this line; 5 small black submarginal vein-dots. Hindwing black with a reddish tint, brightening distally as far as the narrow green marginal line. Colombia, Ecuador. — **fassli** *Gehlen* is somewhat lighter green, abdomen with a fine though distinct median line, forewing with a distinct second oblique line behind the discal dot; proximal half of inner margin not pink but white, the submarginal vein-dots connected by very fine crescents. Hindwing deeper black, with a yellowish-white anal brightening. Bolivia (Rio Songo). — **bitineata** *Gehlen* (98 E e) is larger than typical *rothschildi*, forewing with the same second line as in *fassli*, the following line meets the inner margin at $\frac{2}{3}$. Stigma much larger, the shadow behind it has almost disappeared. Hindwing black excepting the green distal margin, with a slight pink anal brightening. Peru (Chanchamayo).

X. cosmius *R. & J.* (98 E f). Body as in *amadis*, the basal spot on the sides of the abdomen less distinct, strewn with brown on the dorsum, without lines. Forewing concave below the apex, the margin obtusely dentate; brownish wood-coloured with a green tint, the costal-marginal area, a triangle distally to the oblique line between the apex and vein 5, and the anal angle are of a clearer green; the basal part with 3 greenish-brown curved lines not reaching the inner margin, the two exterior ones near together; stigma black, a greenish black spot behind it; an oblique line from the apex to the centre of the inner margin is continued at the inner margin to the base; a submarginal row of vein-dots, the fringe speckled black. Hindwing black with a reddish olive band, somewhat indented on the veins, margin green. South-Eastern Peru. — **obscurus** *R. & J.* (= *pizarro* *Gehlen*) has a much thicker black shadowy spot behind the stigma, the antemedian lines on the median vein, not angled subcostally, the oblique line in the disc basally convex; fringe not speckled. Margin of hindwing quite black, the median band less green. Amazons (Rio Madeira).

X. ockendeni *Rothsch.* Forewing green like thorax, with three spots of a diameter of 3—5 mm, one being subbasal, the 2nd behind the apex of the cell, the 3rd near the anal angle; stigma small, black; a fine

curved black line extends from the subbasal spot to the costal margin, a dark green short line in the centre of the cell, and a feebly dentate dark green line behind the spot at the apex of the cell; another line from behind the centre of the inner margin to the costal margin is distally broadly bordered with dark green; a submarginal dentate line intensified by vein-dots; small dark marginal spots at the ends of the veins. Hindwing brownish-black with a reddish distal band terminating at the anal angle in a loamy yellow spot; margin green with black marginal dots. South-Eastern Peru.

mirabilis. **X. mirabilis** Clark (= *venator* Niep.) (98 F e) resembles both *adalia* and *ockendeni*. Forewing olive green with three black spots, one at the base, another spot behind the cell-end and the 3rd at the anal angle; some indistinct antemedian lines, 2 strong dark brown parallel postmedian lines and a dentate light bluish submarginal line with vein-dots; fringe speckled dark at the ends of the veins. Hindwing blackish-brown with a light brownish subterminal band and margin. Abdomen olive green, laterally scaled white, the last segments edged with white. The green antennae are red beneath. Antioquia, Colombia.

macasensis. **X. macasensis** Clark is near *ockendeni*. Body olive yellow above, dorsum of abdomen with 2 rows of dark dots, light yellow beneath. Forewing yellowish olive with the 3 black spots of *ockendeni*, and a small black stigma; a fine black irregularly curved line extends from the distal side of the subbasal spot to the costal margin; 2 dark yellowish-green slightly dentate lines from the centre of the inner margin to the distal margin below the apex and from here in two black lines to the costal margin; a dark green line from the apex to the inner margin 1 cm before the anal angle, and behind this line a row of dark vein-dots. Hindwing blackish-brown above with an indistinct reddish median band ending in a spot at the inner margin; margin narrow yellowish olive, fringe white, dotted dark at the ends of the veins. Length of forewing: 40 mm. Macas, Ecuador.

chiron. **X. chiron** Dru. (= *sagittata* Goeze, butus F.) (98 E f) is an unmistakable beautiful species varying from green to rusty brown, with one loamy brownish area each traversed and bordered by brown and black dentate lines subterminally in the anal half as well as at the costal margin, with a blackish-brown discal and basal spot, base of inner margin pale yellowish sulphur-coloured with white hairs. Hindwing black with a pale sulphureous black-veined median band. The nomenclatural form from Jamaica is more frequently rusty brown than green with rather indistinct postdiscal lines and very indistinct loamy yellowish subterminal spots. Under surface

nechus. more yellow. — **nechus** Cr. (= *chiron* Wkr., *haitensis* Btlr., *chironnechus* R. & J.) (98 E f) is the continental form distributed from Mexico to Uruguay, but it occurs also in Haiti, Porto Rico and the Bahamas. It is mostly green and but very rarely rusty brown, with very distinct loam-coloured apical and anal spots. — **lucianus** R. & J. has broader forewings, a green apical line and, proximally to it, blackish-brown vein-dots; a large blackish-brown triangular spot in the distal third of the inner margin; the 2 loamy yellow spots are absent altogether. Hindwing with only 3 distinct discal spots, a fourth being feebly marked at the costal margin. Sa. Lucia. —

cubanus. **cubanus** R. & J. is smaller, with shorter forewings, the loam-coloured spots small, also the discal spots of the hindwing smaller and of a more reddish tint; antennae reddish-pink. Body beneath more red-brown. Cuba. — The larva of *nechus* is green with an interrupted black dorsal line, one white ocellus each in red and black rings on the 4th and 5th segments, often yet a yellow ocellus on the 6th segment, feebly lighter oblique stripes in the sides and a black subdorsal line bordered with yellow and white below, on the two penultimate segments; pectoral legs red. On various Rubiaceae and Icacinaceae.

crotonis. **X. crotonis** Wkr. (= *viridescens* Btlr., *aristor* Btlr., *virescens* Ky.) (98 E f). Upper surface varying from green to rusty brown, under surface from ochre to rusty yellow; forewing with 7 postmedian oblique lines, the 4th being the strongest, the 6th often provided with vein-dots. The black hindwing shows 5 wedge-shaped postdiscal spots besides the large yellowish-white longitudinally parted anal spot. The nomenclatural form *aristor* has no longitudinal lines on the dorsum of the abdomen, whereas — **aristor** Bsd. (= *hortulanus* Schauf., *crotonis* Wkr., *nechus* Btlr.) (98 F a) has a light whitish-grey longitudinal stripe across the thorax and abdomen, edged by two fine darker lines. Both the forms and all kinds of transitions occur beside one another from Guatemala to Venezuela and Colombia.

zikani. **X. zikani** Clark (98 F a) is smaller than *crotonis* and *aristor*, of a brighter green than *aristor*; transverse lines distinct, the 1st and 4th stronger and broader than the others, straighter than in *aristor*; tegulae of a purer white, less pink. Length of forewing: 35 mm. Passa Quatro, Minas.

schreiteri. **X. schreiteri** Clark (98 F a) is very near to *zikani*, but darker, the apex of the forewing more produced; the space between the lines 1 and 2 is filled with dark and darker than the rest of the wing, the space behind the cell-end and the costal margin darker, too; lines 1 and 2 somewhat undulated, all the lines more sharply bent towards the apex. Hindwing as in *zikani*. The yellow basal tufts on the abdomen are smaller. Under surface marked as in *nabuchodonosor*, but the lines not black but rusty red. Tucuman (Argentina).

rhodochlora. **X. rhodochlora** R. & J. (98 F a) is somewhat smaller than *crotonis*, bright dark olive green, more rusty red beneath. Shape of wings shorter and broader, the oblique lines of the forewing quite indistinct except the first and fourth, the latter proximally lighter whitish-green, line 6 with vein-dots. South-Eastern Peru.

X. eumedon *Bsd.* (= *ortospina* *Drc.* (98 F a) is similar to *crotonis aristor* in the marking, smaller, of a *eumedon*. more brownish olive colour, the first postdiscal oblique line very strong, confluent with the second, the space between the lines 1 and 3 very light, bone-coloured. The 3 upper subterminal spots on the forewing are more or less confluent. Mexico to Brazil.

X. rhodotus *Rothsch.* (= *rhabdotus* *Oberth.*) is very similar to *eumedon*, the grey abdominal stripe broad, *rhodotus*. parted by a scarcely darker colour, subdorsal ochreous spots at the base. The lines 1 and 4 of the forewing are strong and black, line 4 proximally bordered with yellowish-white. All the spots on the hindwing are separated. South America.

X. nabuchodonosor *Oberth.* (98 F b) has the same ochreous basal tufts on the abdomen as *rhodotus*; *nabuchodonosor*. line 1 is thin, the space behind it as far as line 3 darker green, darkened into a blackish triangular spot at the inner margin, line 4 strong, the space between 3 and 4 dingy yellowish-grey, the following lines very feeble except the last, 1, 3 and 7 slightly undulate-dentate. Hindwing as in *rhodotus*. Bolivia.

X. titana *Drc.* (= *aristor* *Burm.*) (98 F b) is smaller and more slender than the preceding species, of a *titana*. more brownish tinge, the space between the 2nd and 4th oblique lines on the forewing forms a bone-white band which is feebly parted by grey, the space between the 1st and 2nd lines very dark, almost black. Hindwing very pointedly produced, the spots somewhat confluent towards the apex. Mexico to Sa. Catharina. — f. *indistincta* *Closs* shows all the light markings of the body and of the forewing very feebly marked, especially *indistincta*. the double line extending across the thorax and abdomen. According to a ♀ from Sa. Catharina. — Larva brown, more yellowish on the dorsum, the first segments inflated, a black white-ringed ocellus on the 4th ring, somewhat lighter oblique stripes on the other segments. On *Spermacoe*.

X. muelleri *Clark* is allied with *eumedon*, *resta* and *tersa*; body above olive brown with red-edged tegulae, *muelleri*. a red ventrum, thorax beneath orange. Forewing with a dark brown, slightly curved line from the inner margin. 7 mm behind the base, to the apex, proximally bordered with light; the cell before it and an area below it tinted red; a finer parallel line behind the line, and 2 fine lines before the margin. Hindwing as in *eumedon*, but the light submarginal band extends to the anal angle, and the dark marginal band is narrower. Length of forewing: 32 mm. Mexico (Misantla).

X. resta *R. & J.* (98 F b) is very similar to a large *tersa* and intermediary between *tersa* and *crotonis*. *resta*. The grey dorsal band of the abdomen is only distinct on the first segments and parted by dark, light yellow tufts at the base, then a large black lateral spot, the segments 3—6 laterally ochreous. Shape of wings broader than in *tersa*, line 1 of forewing strong, 2 fused with it, 3 and 4 close together, the strongest line is the fifth. expanded into a spot at the inner margin. Spots of hindwing larger than in *tersa*. Venezuela, Peru, Argentina.

X. tersa *L.* (98 F b) is one of the commonest *Sphingidae*, rather small and slender. Forewing mono- *tersa*. tonously brownish, line 1 is the strongest, the space between lines 3 and 5 somewhat lighter. Spots of hindwing well separated, the uppermost small. Tegulae inwards with a rusty yellow stripe, the abdominal sides quite golden ochreous as far as the anal apex, with 3 feeble longitudinal lines above. Widely distributed from Canada to Argentina. — *tristis* *Closs* is an insignificantly darkened form. — Larva with strongly inflated thoracal seg- *tristis*. ments, the brown or blackish body with 7 black, white-ringed ocelli subdorsally, the first on the 4th segment being the largest, the ocelli are situated on a yellowish-white line, blackish oblique lines below it. It lives on *Spermacoe* and *Manettia*. Bahamas.

X. suana *Drc.* (= *evana* *Hmps.*) (98 F b) is more monotonously coloured than *tersa*, more ash-grey, *suana*. or brown, abdomen not yellowish-red laterally. Wings not so elongated, the spots of the hindwing are much smaller and reduced in number.

X. turbata *Edw.* (98 F c) is likewise very similar to the preceding species, the white stripe of the tegulae *turbata*. is inwardly bordered with dark olive. Forewing coloured as in the preceding species, the 1st and 2nd lines forming a broad band towards the apex, lines 3—7 very fine, 4 slightly stronger than the others. Mexico and British Honduras.

X. fosteri *R. & J.* (98 F c) is allied to *turbata* and *robinsoni*. Body above olive with a pinkish-grey *fosteri*. lateral stripe on the thorax and a brownish-grey median stripe; abdomen wood-coloured brown, grey at the base, with 3 indistinct dorsal lines. Forewing brown, dusted darker; lines 1 and 2 strong, more or less confluent, the 3rd fine, the 4th with vein-dots, 4 and 5 especially distinct between vein 4 and the apex; the two distal lines feeble; a brown shadow behind the small black stigma. Hindwing blackish-brown with a dingy pink post-discal band which is brownish towards the costal margin, lighter analwards. Length of forewing: 30 mm. Paraguay.

X. ferotinus *Gehlen* (98 F c) likewise belongs to the *tersa*-group, but it differs in its purer olive green *ferotinus*. colouring, the antennae being much thinner than in *tersa* and not white, but dark grey. Head and thorax dark green, laterally dark grey as far as the apex of the palpus. Abdomen marked as in *tersa*. Forewing with 6 distinct oblique lines, lines 1 and 4 being the strongest, the space between 1 and 4 light brownish. Hindwing less slender and pointed, the postmedian spots small, not yellow, but smoky brownish. Sa. Catharina.

- dolius*. **X. dolius** *R. & J.* Body as in *fosteri*, shape of forewing as in *hydrata*. Forewing brownish, dusted with olive; lines as in *hydrata*, the 4th fine, deeper brown in the upper half, the 5th is only indicated and ends in a brown apical dot; the apical part of the marginal area is lighter than the rest of the wing; stigma large and black. Hindwing blackish-brown with a narrow reddish-yellow postmedian band which is shaded with brown towards the costal margin. Length of forewing: 31 mm. Zamora, Ecuador.
- elara*. **X. elara** *Drc.* (= *elicius* *Mschlr.*, *perviridis* *Rothsch.*) (98 F c). Body and wings above yellowish olive green, more yellowish ochre beneath, ventral side whitish grey; abdomen above with a fine olive green median line. Forewing with a black stigma; lines straight, 1—3 feeble, 4 much thicker, but narrower than in *hydrata*, 5 and 6 quite indistinct; distal margin deeply concave below the apex. Base of hindwing black. Guiana and Venezuela to Paraguay.
- isaon*. **X. isaon** *Bsd.* (= *olivacea* *Rothsch.*) (98 F c). Thorax with a grey median line continued across the abdomen by two bands distantly separating analwards, each of them bordered dorsally by a row of dots. The 1st and 2nd lines of the forewing are confluent forming a strong band, the 3rd thin, the 4th very thick, the space between the 2nd and 4th lighter. Hindwing with a faded reddish postmedian band. Brazil (São Paulo to Espiritu Santo).
- hydrata*. **X. hydrata** *R. & J.* (= spec. *A. Bönningh.*) (98 F d) is very similar to *elara*; fresh specimens green, but they turn very quickly yellowish ochre or even reddish-brown; thorax always without light stripes, abdomen with a fine dorsal line and, on each side of it, a somewhat broader dark line. Forewing with a black stigma, 7 oblique lines behind it, the 4th being the strongest, the 6th broad though feeble, the 7th intensified by fine vein-dots; apex pointed and produced. Hindwing blackish-brown at the base, with a brownish postmedian band which is redder apically. Brazil. CLARK considered *elara* and *hydrata* to be one species, *hydrata* being the redder southern form; but GEHLEN examined the genital organs and found them to be different. There are no transitions whatever between the two species' according to GEHLEN to whom we are indebted for supplying the two specimens figured.
- robinsoni*. **X. robinsoni** *Grt.* (= *curvata* *Btlr.*, *falco* *H.-Sch.*) (98 F d) is a somewhat smaller species; forewing tinted olive, lines 1—3 together form a dark band feebly S-curved and not reaching the apex; 4 is very fine, 5 somewhat stronger, terminating together with 6 into the apex, all the lines except 1—3 dying away towards the inner margin. Hindwing black, the light postmedian band interrupted by the black veins. Abdomen above brown with a fine darker median line, sharply bordered laterally with a lighter colour. Only from Cuba.
- josephinae*. **X. josephinae** *Clark* resembles *damocrita* in the colouring so much that it could be easily confounded, but it is very different; shape of wings longer, lines of forewing straighter; the shadowy postcellular spot is less distinct; the first line proceeding 5 mm behind the base is the strongest, the next 3 lines are fine and light, line 5 is broader and extends from the centre of the inner margin to the apex, the next 3 lines are less distinct again; the colours do not contrast so much as in *damocrita*, the band of the hindwing is more remote from the margin at the costal margin. Length of forewing: 40 mm. Cayuga, Guatemala.
- damocrita*. **X. damocrita** *Drc.* (98 F d) is easily discernible from the preceding species by the thick blackish shadowy spot behind the stigma: lines 1—3 feeble, not reaching the costal margin; 4 very strong, 5 close behind it, but obliterated below 4 and replaced by rusty reddish spots. Hindwing blackish-brown with a dark reddish-yellow postmedian band. Under surface rusty red with a sharply defined greyish-brown marginal band entering in a pointed dent between 4 and 5. Abdomen laterally, between the 3rd and 7th segments, with a rusty red stripe mixed with yellow. Mexico.
- maculator*. **X. maculator** *Bsd.* (98 F d) is larger than the preceding species, otherwise similar, but at once discernible by a black stripe of the tegulae extending across the head to the palpi. Abdomen with 3 fine dark longitudinal lines and on each side a broad one; forewing very similar to that of *damocrita*; inner margin blackened between the lines 4 and 6. Band of hindwing interrupted by veins. The nomenclatural form from Venezuela and
- wolffi*. Colombia. — In *wolffi* *Drc.* the longitudinal lines on the abdomen as well as the spot behind the stigma of the forewing are obliterated; there are 4 lines instead of 3 before the strong line, the first being somewhat dentate. Hindwing with a broader and a less reddish band which is not dentate. Ecuador and Peru.
- aglaor*. **X. aglaor** *Bsd.* (= spec. *A. Bönningh.*) (98 F d). Brownish olive, thorax above mixed with grey, without the dark stripe of the tegulae of *maculator*; abdomen with a fine olive median line, somewhat darker subdorsally and below it on each side with a reddish ochreous longitudinal stripe. Forewing olive grey, lighter at the cell-end and before the apex; the first 6 lines are close beside each other, the 5th being the strongest, besides two other lines behind them parallel to the margin. Hindwing black with a reddish-yellow, not dentate band. Brazil (Espiritu Santo, Rio de Janeiro).
- libya*. **X. libya** *Drc.* (= *aglaor* *Schs.*, *neoptolemus* *Bsd.*) (98 F c). This species and the following *loelia* are very closely allied and often difficult to distinguish. Forewing brown, the first 4 lines arranged in 2 pairs, feeble, 5 stronger, often marked by vein-dots; a black dot at the cell-end, another one also before the apex at the costal margin. Hindwing black with a reddish band which is not broader than the black margin. Under

surface intensely marked, the brownish-grey marginal band forms a sharp inward angle between 4 and 5. Mexico to Peru and Surinam. — **pallescent** *Closs*, according to GEHLEN who possesses the type, is a slight *pallescent*. deviation with more uniformly brown lines and a darker under surface, hindwing with but one broad discal band beneath. Described from Peru (Pozuzo).

X. loelia *Drc.* (= *aglaor* *Schs.*, *laelia* *Drc.*, *neoptolemus* *Bönnigh.*) (98 F c) is extraordinarily near *loelia*. to *libya* and forms a transition to the following *neoptolemus*. The forewing (mostly) lacks the cellular dot as well as the subapical black dot at the costal margin. Hindwing somewhat narrower with a more reddish median band, the black margin more regular and invariably narrower than the reddish band; the vein dots beneath are much less distinct, the marginal band is less distinct and much less angled. Mexico to the Amazons. — **heinrichi** *Closs*, according to GEHLEN, is only a form of *loelia* with differently shaped wings which are somewhat *heinrichi*. shorter with a straighter distal margin; the dark areas of the wings exhibit a greenish tinge: Abdomen with a bright yellow lateral stripe. Described from the Amazons. — Young larva green, adult larva brownish ochreous, with a series of darker dorsal spots, blackish-brown subdorsal lines, a black, white-ringed ocellus on the 4th segment and dark brown lateral oblique stripes. It lives on *Spermacoce* (*Rubiaceae*); it conceals itself by day.

X. neoptolemus *Stoll* (= *trilineata* *Wkr.*) (98 F e) is similar to *loelia*. Forewing more monotonous and browner. Band of hindwing of a much deeper and brighter red, broader than in *libya* and *loelia*, reaching to the costal margin, the proximal margin convex, more sharply defined than in *loelia*. Much redder beneath than the said species. From Mexico to Surinam. — **trinitatis** *Closs* is smaller and has shorter wings of a darker *trinitatis*. colouring; the red band of the hindwing is narrower and not so carmine, but more yellowish-red, the black basal area and the distal band not deep black, but browner. Described from Trinidad.

X. pyrrhus *R. & J.* (98 F f) is very closely allied to the following *thyelia*, but much larger; the light band *pyrrhus*. with the double line on the forewing is broader, the line distally bordering on this band gradually widens from the apex to vein 4; the distal margin is less rounded. Merida (Venezuela), South-Eastern Peru.

X. thyelia *L.* (= *eson* *Mkr.*, *theylia* *L.*, spec. *A.* *Bönnigh.*) (98 F f) is a very characteristic smaller *thyelia*. species; forewing brownish-yellow, the costal-marginal half except the light apex more rusty brown with two slaty black lines from the base of the inner margin to the apex, the space between them filled with rusty brown, a light longitudinal band below them with 2 indistinct lines; hindwing grey with 2 postmedian rows of vein-dots. This nomenclatural form flies from Ecuador to South Brazil and Paraguay. — **salvini** *Drc.* was examined *salvini*. by GEHLEN and M. HERING; it is the northern form from Mexico to Colombia. Wings more slender, the double line, which mostly shows a tendency to coalesce in *thyelia*, is distinctly separated, the light band narrower; the costal-marginal half is darker, more monotonous, the light apical area beneath more distinctly defined, the two longitudinal lines confluent and indistinct.

X. jordani *Clark* (98 F f) is a peculiar small species near to the preceding ones, at once recognizable *jordani*. by the brownish-black basal area being sharply cut away, the whole costal part remaining light yellowish; the double lines of *thyelia* do not terminate at the base, but behind the first third of the inner margin, behind which there are 2 subterminal lines parallel to the margin, the distal third of the inner margin very dark. Hindwing light grey. Costa Rica.

61. Genus: **Phanoxyla** *R. & J.*

Very near to *Xylophanes* and separated by a large tuft of scales on the 2nd palpal joint inside, which only occurs in palaearctic species. Distal margin of forewing irregular, indented between 5 and 3. Only 1 species:

Ph. hystrix *Fldr.* (98 F f) is a quite unmistakable species with crenulate wings. Ground-colour olive *hystrix*. black with lighter olive green areas, a yellowish-white basal inner-marginal spot and a similarly coloured oblique line from the first third of the inner margin towards the apex; the line turns more reddish behind the lower cell-end to the costal margin, broader, notched and traversed by blackish notched lines; a black triangle before the anal angle, distally bordered by a short white notched line. Hindwing black with 6 small light yellowish sulphur-coloured postmedian spots and an inner-angular spot. Mr. GEHLEN had the kindness to give us 1 specimen of this extremely rare species for having it figured; only known from the Amazons.

62. Genus: **Celerio** *Oken.*

This well-known genus containing the palaearctic *Cel. euphorbiae* and *gallii* chiefly differs from the preceding genus in the antennae not being uniformly thin, but distally thickened. Generally of a stronger build, abdomen not so long and slender as in *Xylophanes*. Distal margins of the wings entire. Five representatives in America, two of which have to be considered as forms of palaearctic species.

Type: *C. gallii* *Rottenbg.*

intermedia.

C. gallii Rottenbg. (Vol. II, p. 255, pl. 41 d) occurs in the form — **intermedia** Ky. (= *epilobii* Harr., *chamaenerii* Harr., *galii* Wkr., *oxybaphi* Clem., *canadensis* Guen.) in the nearctic region from Canada to Colorado and Georgia. It differs from the palaearctic *gallii* in the more extensive red colour of the hindwing; base and margins beneath darker brown; the light distal margin of the hindwing is generally somewhat narrower.

euphorbiarum.

C. euphorbiarum Guér. & Perch. (= *celeno* Bsd., *spinifascia* Btlr.) (98 F f). Abdomen with 4 blackish-white lateral spots, the two first of which are mostly jet-black, the next being generally somewhat duller black. Forewing with an olive brown costal-marginal band which looks dentate behind the cell between the veins 4 and 6, owing to deeply entering light veins; no dark spot behind the cell-end; the olive brown subterminal band is widened so much at the inner margin that it is only about 1 cm distant from the base. Hindwing red, the base and a narrow premarginal band black, a quadrangular white spot in the black inner-marginal part. — Larva varying from greyish-green to black, with a light dorsal line and black round subdorsal spots in light yellow rings; on *Mirabilis jalappa*, *Cestrum*, and other plants. From Rio de Janeiro, Argentina and Chile.

annei.

C. annei Guér. (98 F g) is superficially similar to *euphorbiarum*, but it lacks the sharply defined olive brown costal-marginal stripe, the costal-marginal part is only dusted with a slightly darker olive colour and shows indistinct darkening before and behind the cell-end; the subterminal band is much less widened at the inner margin. The black premarginal band of the hindwing is more irregularly defined inwards. Abdomen with 5 black lateral spots. From Peru and Bolivia to Chile.

lineata.

C. lineata F. (= *vitis* Houttuyn, *daucus* Cr., *linearis* Luc.) (98 F g) is a well-known species of an immense range, occurring also in the Old world as *livornica* (Vol. II, p. 256, pl. 41 c). Easily discernible by the white-striped thorax and the white neuration of the forewing; separated from the palaearctic form by a white median stripe on the tegulae and a less white-dotted abdomen which therefore looks less speckled. From Canada to Argentina. — The larva is somewhat less variegated owing to its being less spotted yellow and black.

calverleyi.

C. calverleyi Grt. is a very rare species from Cuba, very similar to *gallii* on the forewings, but with a white-striped thorax as in *lineata*; separated besides from *lineata* by the light band of the forewing not being sharply defined proximally, moreover the abdomen is not dotted white dorsally and without the double row of small black spots of the *lineata*-forms.

15. Family: Notodontidae.

This very large family has not been equably defined by various authors. Especially in recent years attempts were made to separate different groups from this family and to range them under the *Eupterotidae*; sometimes also the *Phalera*, *Rosema* and other genera were given the name of the *Eupterotidae*, and instead of it some genera from this old family were united under another name. Moreover, the name of the family itself has been changed into '*Ceruridae*'. We do not, in a manual, see sufficient advantage in such a schematism to make it worth while going into all the inconformities with the entire previous lepidopterological literature.

The subdivision of the family into several is urged by a certain heterogeny which seems to separate several groups from this union which exhibits the most variegated shapes. If we compare the most homogeneous *Sphingidae*, the *Geometridae* which are quite similarly organised as larvae, the *Zygaenidae* which are in no way connected with any other large family, with the *Notodontidae*, we notice an almost unique variety of shapes even in the larvae of the latter. There are no hairy Sphingid larvae, no bare Lasiolepidid larvae, no Geometrid larvae with more than 12 feet at most, or 10 feet at least, etc.; all these are strikingly contrasted with the *Notodontidae* which sometimes have 14 feet, sometimes 16 feet, and are either hairy or bare. Yet, if we study them more minutely, we find numerous characteristics which are common to all or nearly all the *Notodontidae*. An extremely perfect adaptation to the surroundings both in colour and shape, which is otherwise only peculiar to the older lepidopterous groups, such as the *Geometridae*, many *Noctuae*, and some microlepidoptera, but which is entirely absent in the modern groups, such as the *Zygaenidae*, *Arctiidae*, *Lymantriidae* etc., occurs in nearly all the *Notodontidae*, both in the larval stage and in the imago, whereas the mimetic adaptation to other animals in the perfect insect is not to be found in any *Notodontidae*. Nor can the strange fact that some larvae, for instance those of *Stauropus*, copy spiders and bugs, be attributed to mimicry, since no definite model could yet be ascertained in any case *). In *Aegeria apiformis* we can positively declare a *Vespa* to be the model copied, on account of its dangerous stings, while the larva of *Theretra lucasi* most certainly copies a viper for the same reason. We can even sometimes easily determine the species that has served as its model, and can say that, for instance, the Erycinid *Apodemia stalachtoides* copies the *Stalachtis phlegya*, the *Pseudosphex rubripalpus* the *Polistes ruficornis*, the ♀ of *Chalcusia trepsichrois* the *Euploea (Trepichrois) mulciber*. But we cannot ascertain a definite model of the larva of *Stauropus fagi*, and although the larva of a *Cerura* may appear as a small monster which might seem to be dangerous to animals of a lizard-like size, yet it is not the copy of a certain armed or poisonous insect, of a reptile, a mouse, or any other creature that bites.

The geological age of the *Notodontidae* can also be inferred by considering their geographical distribution. In the warm and temperate regions they are only absent in the Islands of New Guinea, which however are also neglected by all the other families of Macrolepidoptera with the sole exception of the *Noctuae* and *Geometridae*. But though they are not altogether absent in the southern cooler parts of the Earth, in Cape Colony and Patagonia, yet they are of a remarkably rare occurrence there, whereas in the neighbouring countries of the more temperate south, as for instance North Argentina and South Brazil, they appear in great numbers.

If by having recourse to the introductory geographical sketches which we provided for the palaearctic Ethiopian and Indo-Australian *Notodontidae* in other volumes **), we try to form a general survey of the distribution of the family on this earth, we arrive at the following results.

*) Some authors have considered the birch-bug, *Syrphoctonus marginatus*, to be the model, which has an offensive smell and is certainly also scorned by insectivorous animals for this reason. But this resemblance is only noticeable when the insect is approached from behind, and disappears as soon as the animal moves. We must therefore consider this resemblance to be merely accidental.

**) Vol. II, p. 283; Vol. X, p. 605; Vol. XIV, p. 401.

Of the 2300 species known the greatest number occur in America, i. e. about 1400 species. The palaearctic region hardly harbours one tenth of the entire number of species known; the Ethiopian region hardly one sixth, and the Indo-Australian region about one fifth of the whole number. This vast legion of *Notodontidae*, however, is very unequally distributed in America. Most of them occur in the tropics which — as we stated in Vol. X — scarcely excel the temperate northern region on the eastern hemisphere in the number of species; in Asia — especially in the east — we may even meet more *Notodontidae* in the warmer countries of the palaearctic region, than in the plains of Tropical India; in America, on the contrary, the species prevail in the tropical countries.

The peculiar habit of most of the *Notodontidae* living on trees, is of the greatest influence on the distribution of the family in certain regions. The fact that certain districts, also of America, may be entirely devoid of trees, prevents the *Notodontidae* from penetrating to these parts of the country. In Egypt, where many districts even lack the scanty Nile-Acacia, so that there are no trees whatever to be found, except palms and wood-plants introduced from foreign countries, it is useless to search for any *Notodontidae*; only in mountainous North Africa, where wooded valleys occur, do we meet *Cerura*, *Pygaera*, *Hoplitis* etc. Similar regions are found in America, where with an east wind continually blowing the Cordilleras, on their dry side, allow no moisture to fall. The saltpetre district of Iquique where it never rains at all is a good example. Nor could any *Notodontidae* develop in isolated districts of Mexico where there is no timber, and in the southernmost, open country of Chile and Patagonia where the unceasing, roaring wind that tears every tiny plant up by the roots or covers it with sand the moment it appears, the same situation prevails, for no woody plants can thrive; so the *Notodontidae* as well as most of the other *Heterocera* families are conspicuous for their absence.

On the contrary, the number of *Notodontidae* known in the tropical, rainy, wooded districts of America is enormous and increasing continually. The number of (about 30) species newly described in this chapter points to a further increase. The boreal parts of America to the north of Mexico, however, are not much favoured; only 80 species being known from there up to now. The distribution of the family in Mexico itself exhibits the very same fluctuations in the different districts as the timber does.

The concentration of some genera in particular districts is also obviously connected with the vegetation. The fact that some genera are confined to quite definite districts is also distinctly due to the vegetation. Thus we meet an amassment of species of the genus *Schizura* in the northeastern parts of the U. S. A., between Portland and Philadelphia, where 6 of the 8 nearctic *Schizura* are found, whereas PACKARD could identify there scarcely half of the North-American *Datana* which are widely distributed over the whole continent; the species of the genus *Ichthyura* (*Melalopha*) are accumulated in Colorado, near the Springs and in Denver. We must, however, consider that some of these results are to be attributed less to a really abundant occurrence than to the fact that some very zealous collectors were at work in certain districts, who succeeded in tracing the rarer species as well.

From Mexico, from where about 180 species are known, down to the northern parts of South America, the number of known *Notodontidae* increases to such an extent that the number of species yielded by collectors from one single town of Brazil sometimes doubly and even trebly exceeds those found in the U. S. A. In favourable weather, two or three dozen Notodontid species are often captured on the lanterns of Rio de Janeiro or on the large arc-lamps which have been introduced of late even in the remote towns of Central Brazil. A great many members of this lepidopteral family come to the light from afar, and most of them remain fascinated by it, and are unable to leave, whereas Geometrids and, above all, Noctuids are rather frequently able to leave the flame again after having flown around it for a short time.

There is hardly any other way of collecting *Notodontidae* in the tropics but by capturing them at the light. In the temperate zone, where access to the foliage of the trees is easy, most of the members of this family found in collections had been bred from larvae. The success of this method of collecting, however, is not very great. Breeding American species may be just as easy and safe as breeding European species, but the larvae are more difficult to capture when unfamiliar with their habits. Some are polyphagous, but many, as also some Europeans (*Ptilophora plumigera*, *Notod. dromedarius* etc.) entirely or almost exclusively depend on a single food-plant. Others again are confined to a single family of plants, as for instance the *Ichthyura* on Salicaceae; whilst others live only on trees, though they attack lofty-growing wood-plants of various families. Thus breeding is rather difficult owing to this limitation to one or few species of food-plants, since, even if the name and appearance of the plant be well known, it is sometimes very hard to discover an easily accessible specimen for feeding the larvae. And even if the food-tree has been found close at hand, it is sometimes only with great difficulty that fresh twigs can be fetched down from such a height, so that it is then more advisable to shoot fresh branches down with a rifle. In this case, however, another drawback has to be considered, i. e. that freshly broken twigs dry up very quickly, so that the transport from the often distant spot, where the food-plant grows, to the breeding-place of the larvae mostly results in very insufficient sap for feeding them. — It is hardly possible to-day to estimate the geological age from the feeding-conditions,

because owing to the habit of living on trees, the larval stages of but very few species of the enormous number of neotropical *Notodontidae* have been ascertained.

On the whole the *Notodontidae* are regarded geologically as a rather old group from which the more modern *Sphingidae* and *Ceratocampidae* have probably sprung. We have already stated their extremely minute adaptation in Vol. X, p. 607, and Vol. XIV, p. 401. It refers to both the larvae and the imagines and is perfected to such a degree that the absence of any protection by internal saps, smells or acid-bearing organs. There are but few genera that have hairy larvae (such as the *Melalophinae*), most of which are green, smooth, or with a minimum of bristles, but somewhat disguised by their shape; this disguise is often enhanced by a strange quiescent position. A red larva from the genus *Crinodes* bends its head upwards with the first segments in a Sphingid-like way, and at the same time it raises its anal part which is thick and swollen and covered with a peculiar yellow plate, in such a way that its brightly coloured upper surface stares backward like a second head. The larvae of the genus *Datana* bend very similarly, whereas the *Schizura* bend their heads downwards, so that a protuberance on the 5th segment with a sting, which is more than a centimetre long in South-American species, projects in front beyond the larva. The shape of the *Cerura* and *Harpyia*, which is likewise raised in front and behind, is known to us from the European species which are exactly like the American ones in this respect.

The varied shapes of the Notodontid larvae by no means correspond to those of the imagines. More than 90 per cent of these lepidoptera are of a very common, inconspicuous shape, the only — though by no means general — peculiarity being the previously mentioned little lobe or hair-tuft at the inner margin of the forewing, from which the whole family derives its name. On examining the sides of the abdomen, an organ was discovered on the 4th segment, which was named *Cteniophore* by its discoverer (K. JORDAN). It is a kind of movable sting which is supposed to serve for impregnating the long hairs on the hindlegs or also the peculiarly transformed scales on the hindwing beneath with the secretion of an invariably present gland, presumably emitting a certain smell. But these are most inconspicuous formations; the shape of the members of different Notodontid genera does not vary nearly so much as, for instance, the Sphingid genera *Harmorrhagia* and *Celerio*, *Amorpha* and *Deilephila*, or even the *Saturnidae* do, which are sometimes without tails, sometimes with the apices of the hindwings as long as a hand, or the *Mimallonidae* in which, for instance, *Mimallonia amilia* exhibits wings with gnawed-out distal margins, while *Adalgisa croesa* has a long falcated apex of the forewing, and *Tarema macarina* has quite regularly shaped wings.

A striking peculiarity of the *Notodontidae* is the fact that quite similar larvae which are sometimes hard to differentiate, yield most dissimilar and very distinctly separated imagines, while on the other hand imagines which might be regarded as very closely allied come from absolutely different larvae. The former case — along with which a real larval polymorphism as in *Pheosia* — is known to us in Europe from the species *Notodonta ziczac* and *torva* which as imagines are quite dissimilar, while their larvae are only separated by a slight difference in the shape of the middle protuberances. In the same way as the larva of the quite differently coloured European *Not. dromedarius* may, by a frequent violet-brown variation, become more similar to larvae of *ziczac* and *torva* than to its own brothers and sisters, also American larvae of *Dicentria* may resemble certain *Schizura* in their early stages to such a degree that even an expert will find it difficult to identify them. This is the case for instance in the species *Schizura concinna* and *Dicentria lignicolor* which represent regular zigzag-larvae in their early stages having tubercles on the 4th and 11th segments which, by an angular position, reproduce the image of a larva of *Not. torva* or *phoebe*. The growing larva gradually loses every resemblance to the latter, the posterior protuberances increasing in the *Schizura*, while they are reduced in *Dicentria*.

In contradistinction to this peculiarity, the great difference of the Notodontid larvae is not only noticed in the colouring, but still more in the shape of species the developed imagines of which are evidently very closely allied. Thus for instance the North-American *Pheosia rimosa* resembles most minutely the palaearctic *Pheosia tremula* (Vol. II, pl. 45 f). But the American larva has a caudal horn like a Sphingid larva, whereas the European species has a pyramidal elevation on the 11th segment *).

We have already mentioned in Vol. X (p. 606) that the Notodontid larvae, many of which are of a very strange shape, do not always put up with their terrifying positions, but often defend themselves very rigorously. The American species even surpass the European ones considerably in this habit; for while the palaearctic *Dicranura* are only able to spurt fine drops from the slit in the neck towards their foe, the larva of the neotropical species *Anurocampa mingens* receives its enemy with a well-aimed jet of caustic liquid; for

*) PACKARD mentions this case in his monography of the North-American *Notodontidae* comparing it with the behaviour of the larvae of *Acrionia psi* and *A. occidentalis*, where likewise quite different larvae yield very similar imagines, as it also occurs in the palaearctic species *Acrion. psi* and *tridens*. PACKARD mentions that the European adult larva of the Notodontid genus *Pheosia* has a shape similar to that exhibited by the young larva of the American species.

this habit it is named "myador" ("urinator") in its patria — a verbal translation of the scientific name of the species.

The largest *Notodontidae* of the American faunistic region are the *Naprepa* which genus contains the *N. cyllota* that look like a gigantically enlarged *Lophopteryx camelina*. These enormous *Bombyces* are very frequently captured on the lantern. Owing to their resemblance to a dry leaf it is almost useless to search for them in their hiding-place during the day.

The transformation of the exterior of the quiescent imago into a shapeless or puzzling entity is still more extensive in the American *Notodontidae* than in the palaearctic ones, though many species of the former are also only adapted to their surroundings by bark-like or lichenous markings (as in Europe for instance the *Notodonta*, *Dicranura*, *Exaereta* etc.), such as the genus *Heterocampa* comprising hundreds of forms. In the palaearctic region *Stauropus jagi* disguises the exterior of the quiescent insect past recognition by projecting its very hairy tibiae and by advancing the likewise fringed costal-marginal area of the hindwing, whereas some neotropical *Notodontidae* disfigure themselves in repose by an apparently affected and uncomfortable position of their wings and body, to such an extent that it is utterly impossible to discover the insects. Certain *Hapigia* keep their wings still more vertically raised in repose than, for instance, the palaearctic *Pterostoma*; the distal margins of the forewings are closely pressed together, and beside the very sharply projecting "dorsal tooth" the tornus of both the forewings, being tightly folded up, also looks like another hump or splinter.

These *Hapigia* are interesting in more than one respect. Another species, *H. nodicornis* Gn., exhibits transverse stripes similar to the ribs of a leaf, traversing the forewing in parallel rows, but in an opposite direction to that of nearly all other lepidoptera with a similar scheme of markings, i. e. not parallel to the distal margin, but vertical to it. In this way the insect, whose colour is similar to that of a rotting leaf, makes a picture in which the head-end of the resting lepidopteron corresponds to the tip of the leaf, not to the stalk-end. Somewhat allied to this genus is the genus *Antaea*, where the most common species, *A. juturena* Cr., exhibits the veining of a leaf in the usual, normal direction, but the stripes are so much shaded with light and dark on both sides that they have a most strikingly plastic effect, so that even the most expert eye would take them to be erect layers of scales.

The adaptation to broken off pieces of branches which we know from the palaearctic genus *Phalera*, is very common in the American faunal region and appears in various modifications. We find a light yellow luniform spot in the apical region of the forewing of *Navarcostes limnatis* Schs. which is a very rare species. In the neotropical region we meet much more frequently with species in which the light spot representing the place where the copied piece of wood is broken off is removed into the anal angle of the forewing. The lepidoptera which are thus disfigured put their hindwings still more closely together at the margins, when at rest, than the European *Phalera bucephala* do, and usually do not sit transversely or obliquely like the latter, but mostly with their heads up, and appear quite narrow owing to their slender abdomen, the spectator's eye being directed to the anterior surface of the thorax over which the almost nose-like prolonged palpi project like a broken splinter.

Only comparatively few genera exhibit a metallic gloss, such as we notice in the palaearctic *Spatalia* and the *Tarsolepis*. Bright golden magnificent spots distinguish the fairly large species *Chliara croesus* Cr. which frequently comes to the arc-lamps of the towns and of the pleasure-grounds of the Organ Mts. A very large reflecting silvery spot is exhibited by the smaller *Notoplusia clara* Cr., the shape of its spot on the forewing resembling that of *Tarsolepis javana* (Vol. X, pl. 79 a). Otherwise, there are only single metallic lines to be noticed, as in many *Calledema* (*plusia*, *plusioides*, *argenta*, and other species).

We have met a peculiarly coloured type already in the Indian *Notodontidae*, in which the costal area of the forewing is in striking contrast with the rest of the wing. Some forms (*auritractata* Mr., *affinis* Roths., *costalis* Mr.) of the Eastern Asiatic *Spataloides* Mats. show a bright yellow costal-marginal area standing out sharply against the dark brown anal-marginal half of the forewing. We also find in tropical America quite a similarly coloured type: *Lirimiris truncata* H.-Schäff., showing the same distribution of colours. Then again, on the other hand, a dark stripe along the costa may stand out against the otherwise light surface of the often silvery shimmering wings, as for instance in *Lirim. lignitecta* Wkr., where the costal margin of the forewing looks as if it were charred.

The above-mentioned bark-colour which, as in numerous palaearctic *Notodontidae*, conceals the lepidopteron by the adaptation of its vestiture to the rimose bark of various wood-plants is extremely common. The names of the species *xylinoides* (*Dicentria*), *lignicolor* (*Janassa*), *lignaris* (*Arhacia*) and others, intimate this protective colouring, and some resting lepidoptera of this group, such as *Arh. meridionalis*, look like a gigantic projecting chip of wood. There are even species (from the genus *Gisara*) that look like a piece of bark which has been struck by an axe, the distal surface of the wings representing the intact bark, whilst the basal areas represent the chip which has been laid bare by the stroke of the axe.

When early stages come to be better explored, a large number of American Notodontid larvae will presumably prove to feed from Monocotyledons. The colouring and marking of some species, such as *Pronerice disjuncta*, is so peculiarly adapted to the stalk of a reed that only a Typhacea or Graminea can serve these lepidoptera as its place of repose, if not as food. This would only correspond to the cases mentioned in the Indian part of this work, where the *Norraca* were stated to be adapted to a bamboo-leaf and the *Dinara* (*Anticyra*) to a broad blade of grass or reed, to such a degree that one may readily assume a connection of the lepidopteron with these plants.

The *Notodontidae* generally vary little geographically, nor does the seasonal dimorphism noticeably occur in many double-breeding species, and the sexes are generally more alike than in most of the other *Heterocera*-families. Nevertheless there are some of the American *Notodontidae* which also exhibit very strange sexual differences. For instance, the ♀ of the species *Antiora subfulva* Wkr. (*ochromixta* H.-Schäff.) differs so much from the small ♂ that it seems to belong to quite a different genus, i. e. the genus *Lobeza* which is very widely separated from the *Antiora*.

As to the system of the *Notodontidae*, i. e. the grouping and order of the genera, the various authors deviate considerably from one another, which fact is due to the different genera being rather closely allied. In those cases where the larvae are particularly much alike, the imagines, as we mentioned above, exhibit little conformity, and vice versa. Yet we do not meet with many gross errors in ancient literature. *Colax apulus* Cr., for instance, was sometimes mistaken for a *Sphingida*, probably owing to the approximate habitus of a *Parum colligata* (Vol. II, pl. 38 b); this does not appear to be such a great mistake, since the *Sphingidae* have presumably sprung from this very group. The *Nystalea virgula* Fldr. shows an exterior, shaped somewhat like the Sphingid group of *Chaerocampinae*. Moreover, the vast genus of *Hemiceras* (containing more than 150 forms) was assigned to the *Noctuae*, probably chiefly owing to the strongly developed proboscis. Nearly all the *Notodontidae* exhibit the beginnings of a proboscis, but in most of the American forms it is, as in all the boreal and European species, without any function, mostly only a stunted, feeble thread. That is also the reason why, owing to the impossibility of taking food, the species lacking a proboscis have a very short life as imagines, limited to a few days which are entirely spent in copulating and depositing eggs.

The lack of an internal protection which, on the one hand, has led to almost fantastic adaptations to the surroundings, on the other hand also forbids, of course, glaring colours whereby the lepidopteron would only be disclosed to its enemies as a savoury prey. We therefore find, for instance, orange colours but very rarely in the *Notodontidae*, and then only in the hindwing (of the genus *Ruda*) which, however, is covered by the forewing when the lepidopteron is in repose. Sometimes the protection is more important for the ♀ for the sake of preserving the species — as it is also better developed in the whole insect kingdom — than in the ♂; for instance in the common *Dicentria xylinoides* the ♀ of which, resting on dry leaves or old wood, is hardly to be recognized.

1. Genus: **Calledema** Btlr.

A small number of well characterized species which are mostly distinguished by a silvery streak on the forewing in the upper half of the postmedian or subterminal area. The long antennae are tuftedly ciliated, the porrect palpi long, especially the second joint. The forewing has a pointed, often almost falcate apex; distal margin rounded in the upper half below which it extends obliquely to the inner angle. Vein 6 from the upper cell-angle, the 3 median subcostal branches arise on a joint stalk. 3 and 4 of hindwing arise from the same place at the lower cell-angle, 6 is stalked with 7.

Type of genus: *C. marmorea* Btlr.

C. marmorea Btlr. (143 a) is irregularly watered on dark blackish brown forewings; the markings are somewhat like those of the other species; transverse lines whitish, rather indistinct and irregular, a somewhat oblique white longitudinal streak extends from the cell-end to the margin, whereby the species also resembles certain species of the genus *Pseudantiora*. Hindwing brownish-grey. Colombia, Brazil.

C. sodalis Btlr. (143 a) approximates the next group of species. Forewing light red-brown, with fine silvery white veins in the marginal area, interrupted by a white band which is curved S-like and is broad in the upper half, narrow below; a silvery white streak from the cell-end to the centre of the margin; a narrow brownish reniform macula at the cell-end. Hindwing brownish-grey, lighter towards the base. Brazil.

C. plusia Fldr. (143 a) is darker purple brown than *sodalis*, with distinct blackish antemedian and postmedian transverse lines; the lower half of the median area before the postmedian line is darkened blackish; the silvery white subterminal band is narrower on the whole, removed more inwards and double in the upper half, the silvery longitudinal stripe also parted by a black longitudinal line. Hindwing brownish-grey. Brasil.

- plusioides*. **C. plusioides** *Fldr.* resembles the preceding species; forewing light red-brown, much lighter in the distal half of the inner margin, the absent transverse lines are replaced by a yellowish spot before the middle below the cell, bordered on both sides by erect silvery scales; the silvery white subterminal band is threefold in the upper half, the 3 parts being divided and terminating into the margin on the 3 lower veins. Hindwing brownish-grey. Colombia to Brazil.
- arema*. **C. arema** *Schs.* (143 a) is somewhat smaller than *plusioides*, but very similarly marked. Forewing violetish brown, reddish in the costal-marginal area, with a lilac tint at the inner margin, veins 2—4 speckled grey and black, with a yellowish silvery antemedian spot below the cell, parted by dark and distally bordered by erect brown scales; a dark brown spot at the cell-end, a silvery stripe extends from this spot to the yellowish-brown subterminal area as in *plusioides*. Hindwing whitish at the base. Costa Rica to Guiana.
- argenta*. **C. argenta** *Schs.* is a much larger species. The violetish brown forewing shows lighter veins in the median area; an olive brownish antemedian line bordered with silvery crosses the cell, a fine silvery dent extends to the base; a silvery line distally along vein 6 as far as the white submarginal line which is bordered with yellow in the upper half; this colouring is strongly widened apically, oblique yellow streaks extend from the lower half to the margin. Hindwing brown. Expanse of wings: 43 mm. French Guiana.
- sura*. **C. sura** *Schs.* is the smallest species of all, with brown forewings which are tinged reddish-yellow towards the costal margin, more lilac towards the inner margin; the cell and a shadow behind it are darker brown, a broad whitish subbasal area is divided by a greenish-yellow line; a white transverse streak is in the cell, a silvery white line behind it extends to the broad white submarginal band which is traversed by a grey and yellowish line and narrows down below the centre to a white line. Hindwing violetish-brown. Expanse of wings: 26 mm. Brazil.
- jocasta*. **C. jocasta** *Schs.* (143 a) almost looks like a species of *Pseudantiora* with light olive grey forewings transversely watered with white, an indistinct double red-brown basal transverse line and a red-brown and black longitudinal line from the basal third of the costal margin through the cell between 5 and 6 to the distal margin; a red-brown spot is below the median vein at the place from where the lower branch arises, another quadrangular subapical spot at the costal margin. Hindwing brownish-grey. Brazil.

2. Genus: **Drastoma** *Schs.*

The only representative of this genus is a large, quite uncommonly coloured lepidopteron with long narrow forewings and a slight angle at the distal margin between the upper radial branches; vein 5 of forewing arises from the upper cell-angle, 6 arises before the end of the accessory cell; the two lower subcostal branches on a joint stalk. Hindwing as in *Calledema*.

Type of the genus: *D. dardania* *Drc.*

- dardania*. **D. dardania** *Drc.* (143 b). This unmistakable, most conspicuous insect is dark cerise in the costal-marginal part of the forewing, yellowish below it; described from Honduras and Costa Rica, occurring as far as Colombia.

3. Genus: **Pronerice** *Schs.*

Palpi especially long in the first and second joints, ♂ antennae pectinated. Forewing similarly long and narrow as in *Drastoma*, but the costal margin much more convex; the stalk of the two lower subcostal branches is much longer than in *Drastoma*, accessory cell very long and narrow, 6 and 7 arise from its end. All the branches on the relatively large hindwing arise without a stalk. Only two species.

Type of genus: *P. disjuncta* *Dogn.*

- disjuncta*. **P. disjuncta** *Dogn.* (143 b). Forewing yellowish-grey, traversed by a black longitudinal line on the border between the upper and middle thirds, this line being slightly shaded above and bordered with whitish below, and showing a roundish convexity downward at the cell-end. Colombia, Bolivia, Ecuador.
- cymantis*. **P. cymantis** *Schs.* is much smaller than *disjuncta*, the brown forewing shaded with blackish and strewn with grey except the distal margin, with a black cellular dot and a velvety black cross-vein; a postmedian row of black vein-dots, the veins before and behind them dusted with light brown; black marginal dots between the veins, fringe black, spotted brown on the ends of the veins. Hindwing dark brown, almost black distally. Expanse of wings: 38 mm. Guiana.

4. Genus: **Tagela** *Schs.*

Palpi more erect than in *Pronerice*, antennae tuftedly ciliated; forewing broader, with a straight costal margin; vein 6 arises before the end of the accessory cell, the two lowest subcostal branches not stalked. Veins 6 and 7 of hindwing on a short stalk. Three species have been described so far.

Type of genus: *T. dentata* Schs.

T. dentata Schs. (143 b). Exterior somewhat like that of *P. disjuncta*, but smaller and darker brown, *dentata*. the whole basal half of the costal margin black, more reddish-brown distally. Hindwing brown. Brazil (Rio de Janeiro).

T. cayuga Schs. has dark brown forewings strewn with blue and traversed by numerous black undulate *cayuga*. lines which are broad light brown at the inner margin and in the apical half of the costal margin, the black undulate lines on this light area are likewise only somewhat darker than the ground; black spots before the centre and at the lower cell-end, and a dark streak below the middle radial branch to the undulate line. Hindwing dark greyish brown. Expanse of wings: 46 mm. Guatemala.

T. noctuidiformis Dogn. (= *cossula* Rothsch.) (143 b) deviates somewhat from the diagnose of the *noctuidiformis*. genus, since the antennae are only finely ciliated, the legs more thickly haired, vein 5 of forewing arises a little below the upper cell-angle. Forewing brown, strewn lighter and mixed with yellowish in some places, with a light, strongly dentate anterior transverse line which is partly bordered with black, and a broad black postmedian line bordered with light on both sides and extending from the costal margin almost straight to the anal angle; a light-centred discal spot at the cell-end is encircled with black; instead of the undulate line there are light small spots partly shaded with black inside, an irregular black marginal line behind them. Hindwing white, brownish at the margin. Peru.

5. Genus: **Dyasia** Schs.

This genus has much shorter palpi, the last joint being entirely hidden in the hair. ♂ antennae tuftedly ciliated. Wings short and broad; vein 6 of forewing arises from the centre of the accessory cell, the two lower subcostal branches arise not stalked from the end of this cell. Hindwing almost like that of *Calledema*. The ♀♀ are much larger.

Type of genus: *D. viviana* Schs.

D. viviana Schs. (143 b). Basal third of forewing whitish, scantily strewn with brown, reddish yellowish *viviana*. brown in the median area, the distal margin lilac with velvety brown spots in it, the two former colours defined by a curved black line; a yellowish-white spot at the cell-end encloses a reniform macula which is surrounded with brown; the posterior transverse line is steel-grey, deeply dentate, a brown dentate line behind it, and yellowish-white vein-spots. Hindwing white with a brown marginal line. The violettish-grey marginal colour extends to the median area in some specimens. French Guiana.

D. juvencula Dogn. Base of inner margin, interior area and marginal area of forewing whitish, scantily *juvencula*. strewn with brown, the rest, also the inner margin, more intensely brownish, with a blackish-brown apical spot and chocolate-brown transverse lines, the anterior ones pointedly broken basad in the cell, in the shape of the point of a lance, the posterior one double, filled with white and more intensely marked in some places. Hindwing white, brownish on the veins and at the margin. Expanse of wings: 29 mm. Amazons.

D. punctata Rothsch. (143 c) has brownish forewings dusted with lilac pink, with 2 broad brown *punctata*. shadowy bands and brown irroration; transverse lines composed of small round black spots of various sizes; 2 large black subapical spots. Hindwing light brown, darkened at the margin. Amazons.

D. stigmatica Rothsch. (143 c). Forewing sooty brown with a purple tint, rusty brown in the basal *stigmatica*. third and streaked black, a broad red-brown, black-spotted antemedian band; these striae are very scanty in the two marginal thirds, a postmedian row of small red-brown, black-centred spots, a large rusty red subapical spot encloses a broad blackish-brown band. The whitish hindwing is slightly tinged grey at the margins. Amazons.

6. Genus: **Antioira** Wkr.

Only one species with broad wings; ♂ antennae pectinated. Vein 5 of forewing arises from the centre of the cross-vein, 6 from the upper cell-angle, the 4 lowest subcostal branches on a joint stalk from the end of the accessory cell. 3 of hindwing stalked with 4, and 6 with 7, 5 arises near the upper cell-angle.

Type of genus: *A. subfulva* Wkr.

A. subfulva Wkr. (= *ochromixta* H.-Schäff.) (143 c) is sexually very dimorphous, the ♂ small with *subfulva*. narrow wings, the ♀ very robust; both are similarly coloured and marked, ash-grey, finely strewn white and orange, with black notched transverse lines and a whitish discal line; the whitish sinuate undulate line is shaded darker inside. Hindwing light grey, the ♂ blackish and thinly scaled. Brazil.

7. Genus: **Anurocampa** H.-Schäff.

The typical representative of the genus is presumably the largest Notodontid known, a somewhat smaller species was described of late beside it. It chiefly differs from the preceding genus in the non-stalked

veins from the lower cell-angle of the hindwing, and beside vein 5 of forewing arises a little above the centre of the cross-vein.

Type of genus: *A. mingens* H.-Schäff.

mingens.

A. mingens H.-Schäff. (143 d). This gigantic well-known species has greyish-white forewings strewn with blackish, with 2 broad greenish-grey transverse bands; hindwing blackish, the basal portion and inner margin bright ochre; the black abdomen shows yellow bands. It is widely distributed in Colombia, Brazil and Argentina. Larva thick, green, increasing in thickness on the 3 first segments and forming a transverse protuberance on the third segment, and with a broad white subdorsal line. On being touched, it spirts out a water-like liquid as from a syringe, for which reason it is called "myador" (= urinator) by the natives.

albifasciata.

A. albifasciata Schs. is much smaller with blackish-brown forewings, a yellowish-white dot at the base of the cell and two whitish transverse bands, the anterior one of which is divided into spots, the posterior one broader, especially in the middle, and traversed by the dark veins. Hindwing unicoloured blackish-brown. Abdomen with yellow transverse lines on the black ground. Expanse of wings: 50 mm. Argentina.

8. Genus: **Nadata** Wkr.

Antennae pectinated to the tips, palpi short. The thorax bears a rather high sharp dorsal ridge. Forewing with a notched distal margin, neurulation similar as in the preceding species, but vein 7 of forewing free and not stalked with the higher ones. Hindwing as in *Anurocampa*. America has but one typical representative, but there are several other species occurring in the eastern palaearctic region.

Type of genus: *N. gibbosa* Abb. & Sm.

gibbosa.

N. gibbosa Abb. & Sm. (143 c) has light ochreous forewings with 2 brown transverse lines convergent towards the inner margin, and a whitish discal streak. The species is found from Canada to California, Florida, and Texas. The dull green larva with a whitish dorsum, a yellow lateral stripe and red stigmata lives on oak,

behrensi.

but also on other foliaceous trees, such as maple, birch and plum. — f. **behrensi** Edw., which is hardly worth being denominated, is somewhat larger, forewings lighter and more pointed on an average; it is the form

double-dayii.

from the western coast. — The type of the form **doubledayii** Pack. shows the palpi beneath and the front legs somewhat darker, whilst other specimens lack the mostly double white discal dot which is then replaced by

rubripennis.
oregonensis.

a darker blotch. — f. **rubripennis** Neum. & Dyar is the name of darker rusty reddish specimens. — f. **oregonensis** Btlr., however, denotes dark blackish-brown specimens with more brownish-grey hindwings. From Oregon.

9. Genus: **Cargida** Schs.

Distinguished from the preceding genus by more smoothly margined forewings; vein 3 of hindwing arises separated from 4, and vein 6 is not stalked with the subcostal branch. The genus contains but one species from Mexico.

Type of genus: *C. pyrrha* Drc.

pyrrha.

C. pyrrha Drc. (143 d). The whitish-grey species exhibits two sharply notched transverse lines and almost black hindwings; it is particularly distinguished by the orange abdomen. The ♂ is much darker and smaller. The species is known from Mexico, but it has also been reported from Arizona. — f. **intensa** Rothsch. is the name of this latter form which is much darker with more distinct markings than those of typical specimens.

10. Genus: **Minara** Wkr.

Antennae of ♂ pectinated, of ♀ plain, the hairy palpi straightly porrect, with a rather long terminal joint. Vein 5 of the relatively broad forewing arises from the centre of the cross-vein, 6 from the upper cell-angle; veins 8 and 9 on a short stalk at the end of the long accessory cell. The two branches on the hindwing arise separately from the lower cell-angle, those from the upper one being stalked. The only South-American species resembles an Arctiid.

Type of genus: *M. histrionica* H.-Schäff.

histrionica.

M. histrionica H.-Schäff. (= *pardalina* Wkr.) (143 d) has a blackish-brown body with a yellowish-curved abdomen and light yellowish-brown forewings with irregular black spots assuming the shape of longitudinal stripes in the distal half. Brazil.

11. Genus: **Nerice** Wkr.

The only American representative of this genus which occurs also in the eastern palaearctic region has a structure similar to that of *Minara* from which it chiefly differs in vein 6 arising from the end of the accessory cell, and a shorter terminal joint of the palpus.

Type of genus: *N. bidentata* Wkr.

N. bidentata Wkr. (143 e). This well-known, very characteristically coloured species the forewing of *bidentata*, which is grey at the inner margin, lighter silvery white towards the brown costal-marginal part, chiefly occurs in the northern and eastern parts of the U.S.A. and in Canada, and seems to be absent in the west. The larva is whitish bluish-green on the dorsum, darker beneath, with strong two-pointed dorsal humps which are turned forward and excellently protect the larva resting on its food-plant, the leaf of an elm-tree.

12. Genus: **Nystalea** Gn.

A very well characterized genus resembling the *Cucullia*, with long, narrow, pointed forewings. ♂ antennae more or less tuftedly ciliated, palpi rather short, very hairy, with long erect tufts of scale-hairs. Neuration chiefly like that of the neighbouring species, mainly distinguished from the preceding ones by only 7 and 8 of forewing being stalked and vein 6 generally arising near the proximal beginning of the accessory cell; the costal branch on the hindwing arises near the cell-end. — The larvae, as far as they are known, are exactly like those of the palaearctic *Notodonta* (*ziczac* etc.).

Type of genus: *N. ebalea* Cr.

N. julitha Schs. (143 e). Head and prothorax brownish-black, the rest of the body like the forewing *julitha*, light wood-coloured, with the beginnings of double lines at the costal margin; cellular fold and veins behind the cell finely striped dark; a double angular line in the centre of the inner margin, and a fine streak at the cell-end; traces of a postmedian line and of an undulate line above the anal angle. Hindwing brownish-grey, darker at the margin. Expanse of wings: 60 mm. Brazil, Rio.

N. ebalea Cr. (= *conchyfera* Gn.) (143 e) is the oldest and most widely distributed species known with *ebalea*, a wood-coloured brown forewing which is darkened deep blackish-brown in the costal-marginal part, especially towards the apex, with small light brown, darker centred spots in the centre of the costal margin and at the apex, indistinct deeply notched transverse lines, and a thick black dot above the centre of the inner margin. Hindwing diaphanous whitish, with darker veins and a blackish-brown marginal band. From Mexico to Brazil and Colombia.

N. eutalanta Dyar is very similar to *ebalea*, somewhat smaller and of a more compact structure, the *eutalanta*, light costal-marginal spot is whitish and much larger so that it includes the reniform-macular spot, the marginal area is lighter. Described from Florida, in March.

N. porgana Schs. (143 e), likewise allied to the two preceding species, has brown forewings, strewn *porgana*, darker brown and grey in the cell and on the veins, with indistinct double transverse lines and a large olive brown costal-marginal spot at the apex, enclosing a black streak and edged with white and reddish-yellow; the veins 4—6 are shaded with dark brown on both sides. Hindwing light brown, darker at the distal margin. From Guiana.

N. parsoni Schs. (143 f) is smaller than the similar *porgana* and more variegated, the light apical spot *parsoni*, is longer and narrower. Forewing purple brown, inner margin and distal margin reddish-olive excepting the area between 4 and 6, the markings blackish-brown; a black and white streak on the base of the median vein, the three transverse lines double, filled with light reddish-brown; a long narrow reniform macula at the cell-end is reddish with black lines, a curved black line behind it with a brown spot at the submedian fold; the postmedian line is scaled white distally, a sinuate light brown line is behind it; subterminal red-brown lunules are white distally, small dark marginal spots above the anal angle. Hindwing brown, lighter towards the base. Expanse of wings: 65 mm. Bolivia.

N. amatura Schs. is very similar to the ♂ of *marmorea* (143 f); forewing darker and more uniformly *amatura*, brown, the light apical spot shorter, bordered below with a white line which does not reach the margin; reniform macula vertical, bordered by dark lines and without any white; hindwing white, dusted somewhat brown, the margin and veins darker brown. Expanse of wings: 52 mm. British Guiana: Amazons.

N. difficilis sp. n. (143 f) is very closely allied to *ebalea* and also *amatura*, at once separable from these *difficilis*, two species by dark greyish-brown hindwings as well as by two thick black spots above the anal angle. Colouring very similar to that of a very dark *ebalea* (143 d), but much more monotonous: transverse markings only visible with the aid of a magnifying glass, the reniform macula is entirely absent, only the fine postmedian white oblique streak between 4 and 5 is distinct; veins finely strewn black and white; apical spot shaped as in *porgana*, but much darker, greyish-brown with a yellowish tint, enclosing a short thick black longitudinal streak; the anal region is somewhat lighter and more brownish, with 2 thick black submarginal crescents in it. Hindwing dark greyish-brown, feebly lighter towards the base, with brownish-white fringe. According to 1 ♀ from Teffé (Amazons); type in the Berlin Museum.

- marmorea*. **N. marmorea** Schs. (= *mocotana* Schs.) (143 f) has dark greyish-brown forewings with indistinct transverse lines and a dentate brown subterminal line behind which there is a row of small velvety brown, light-edged spots; large whitish spots more distinctly showing the transverse markings are in the centre of the costal margin, at the apex and interior angle. Hindwing diaphanous white in the basal half, blackish-brown at the margin. Trinidad; Venezuela, Colombia.
- idonea*. **N. idonea** Wkr. (143 f) and the two following species form a group of closely allied forms which are distinguished by 2 large round subterminal spots from a whitish to a reddish-yellow colour on the forewings; these spots may also disappear, and the species seems to be rather variable, on the whole. Forewing olive greyish-brown, irrorated darker and whitish, with indistinct double dentate transverse lines and an almost cordiform reniform macula, the point of which is turned inward. Hindwing greyish-brown. Head and collar from reddish-yellow to blackish-brown. Colombia, Bolivia.
- guzmani*. **N. guzmani** Schs. (143 f). Forewing olive brown with fine undulated transverse lines; a whitish cellular spot before the centre and a costal-marginal streak above it; a dark brown oblique stripe behind the double median line extends from the costal margin to below the median vein; the large irregular discal spot is surrounded with white, and dusted with white on both sides; the large white apical spot extends to the posterior transverse line and encloses a short black streak. Hindwing brownish-grey, lighter towards the base. Costa Rica to Colombia.
- albipicta*. **N. albipicta** Schs. (143 g) is similar to the two preceding species, but easily separable by the white head and palpi as well as the orange brown tuft of the vertex and the collar; the double transverse lines are also partly filled with orange; the white median spot is larger and reaches the interior lower end of the apical spot the centre of which is slightly strangulated; small white spots are also in the centre of the subterminal line. French Guiana.
- marona*. **N. marona** Schs. Forewing light brown, strewn with darker brown, black and grey, so that all the markings become very indistinct, with double brownish transverse lines and a double velvety black cell-end streak which is closed above; the posterior transverse line is black between the veins, a thick black crescentiform line behind it, being broadest on vein 5; the submarginal line is also velvety black, bordered with grey distally. Hindwing dark brown, lighter in the basal half. Expanse of wings: 51 mm. French Guiana.
- multiplex*. **N. multiplex** Dogn. (143 g) has a greyish-brown ground-colour, marbled olive and yellowish in the cell, in the median area, apically and in the inner-angular third, traversed by numerous irregular olive transverse markings; renimacular spot olive, bordered with black, a black transverse bar before it is bordered with light inside; 2 large olive subterminal spots above and below the centre are bordered with black inside and often with white outside, followed by a yellowish-white and, behind it, a black undulate line. Hindwing whitish, broadly bordered with blackish-brown. French Guiana.
- sequora*. **N. sequora** Schs. Forewing grey with double black transverse lines, the posterior line treble, followed above the centre by a black line, below it there are brown spots and a series of steel-grey subterminal spots; reniform macula darker grey, bordered with velvety black. Hindwing brownish-white, darkened at the margin. Expanse of wings: 54 mm. British Guiana.
- corusea*. **N. corusca** Schs. (= *nigriplaga* Roths.) (143 g) is a very large species with relatively broad wings; forewing olive brownish, lighter in the basal third, with darker longitudinal stripes between the veins, with notched blackish transverse lines, a thick black cell-end dot and a black stripe before it; a broad slate-blackish shadowy stripe extends from the third quarter of the costal margin to the distal margin below the apex, a darker triangular spot is above it before the apex. Hindwing brownish, lighter towards the base. Brazil.
- zeuzeroides*. **N. zeuzeroides** Roths. is stated to be nearest to *discalis*, the silvery mouse-coloured forewing exhibits numerous brown and white transverse striae partly representing notched transverse lines; a grey spot finely surrounded with brown is at the cell-end, a brown subcostal streak is postdiscally. Hindwing dark brown, lighter towards the base. Expanse of wings: 66 mm. Amazons.
- lineiplena*. **N. lineiplena** Wkr. (= *cucullia* Fldr., *congrua* Dyar) (143 g). Forewing brownish, with darker longitudinal stripes and a deep brown shadow along the median vein to the distal margin, widening from the cell-end to the upper radial branch, a black discal dot in the lower cell-angle. Hindwing whitish with a narrow dark brown distal margin. Brazil.
- malga*. **N. malga** Schs. (143 g) is somewhat similar to *lineiplena*, but much smaller, likewise light brown, the dark brown longitudinal stripe much broader from the base, terminating at the distal margin between 4 and 7, with black longitudinal streaks between these veins; two indistinct spots surrounded by light brown are in the cell; double transverse lines only at the costal margin, only the posterior one is also distinct at the inner margin. Colombia, Rio de Janeiro.
- nigritorquata*. **N. nigritorquata** Dogn. (= *alba* Dogn.) (143 h) has greyish-white forewings with very feeble, brownish, oblique shadowy transverse lines proceeding from darker brown costal-marginal spots which are double distally; the median vein and veins 4 and 5 are fine black, a double, very oblique black line from the lower cell-end to the base on the submedian fold; a thick black spot above the anal angle. Hindwing diaphanous white with fine brown veins and margin. Colombia, Brazil.

N. scarra Schs. also has whitish-grey forewings with a broad brown costal margin as far as the double *scarra*. antemedian line which proceeds from a deep black costal-marginal spot, with black dots and streaks before it; cross-vein shaded brownish with black scales behind it; then follows a curved brown shadowy stripe with a black dot below the cell; the veins behind the cell are striped black as far as a straight blackish-brown double line behind which a narrow brown shadow follows, enclosing white and black vein-dots; a black subterminal spot between veins 4 and 5, and a black line above the anal angle. Hindwing greyish brown with white fringe. Expanse of wings: 45 mm. Guatemala. Probably the ♀ of the following *postpuncta*.

N. postpuncta Schs. is a smaller species also with whitish forewings which, however, are strewn with *post-* light brown, the marginal area dusted light brown, with double brown transverse lines, the median line treble, *puncta*. partly shaded with ochre; an irregular brown spot on the cross-vein, the cellular branches are black as far as the posterior transverse line behind which there are black and white vein-dots, and a round black spot between 4 and 5; the velvety black undulate line is irregular and interrupted. Hindwing whitish, veins and margin greyish brown. Guatemala. Expanse of wings: 42 mm.

N. indiana Grt. (= *guttulata* Schs.) (143 h). Forewing light grey, somewhat brownish behind the *indiana*. anterior double transverse line, dusted with reddish yellow in the marginal area; behind the large cellular spot, which is bordered by velvety black, follows a dark transverse line widened at the inner margin, and behind it a fine straight red-brown line; behind the double postmedian line, which is filled with dark grey, follows a row of reddish-brown spots, behind them double black dots and larger dark brown marginal spots. Hindwing whitish, blackish-brown outside. Florida, Cuba.

N. eastmani Schs. is somewhat similar to *indiana*. Basal part of forewing greyish-white, bordered by *eastmani*. the fine, partly double antemedian line, median area light reddish-brown, bordered by a double dark line which is angled on 3 and undulated below the cell; 7 black dots along the centre of the cell; a white postmedian area, strewn with dark, is traversed by a fine dark line, and a brown and black line between 4 and 5; distally bordered by a double dark undulate line, then follows a cinnamon-brown shadow with darker brown spots; marginal area reddish-brown, distally strewn with white, with dark brown lunules. Hindwing greyish-white, veins and margin brown. Expanse of wings: 49 mm. British Guiana.

N. plumipes Schs. (143 h) has grey forewings strewn with reddish-brown and partly shaded with green, *plumipes*. with undulated brown transverse lines, a broad brown and grey shadow behind the distal line; a series of black dots in the cell. Hindwing brown, whitish towards the base. Venezuela.

N. biumbrata Schs. is nearest to *plumipes* in its marking. Forewing silvery grey, dusted darker before *biumbrata*. the centre and in the marginal area; the antemedian area, behind the fine irregular black transverse line, is bordered by a double reddish orange brown line which is sinuate at the costal margin and on the median vein, with small black spots at the indentations; discal line whitish, scaled black, a dark crescentiform line behind it; postmedian line double, blackish-brown, undulated in the lower portion, a dark brown crescentiform line behind it; deep black internerval dots subterminally, blackish-brown marginal dots behind them. Hindwing white, veins and margin narrowly blackish-brown. Expanse of wings: 50 mm. Argentina (Tucuman).

N. olivescens Schs. (= *obliquata* Schs.) (143 h). Forewing light grey below the base of the cell and *olivescens*. at the inner margin, strewn darker, brown at the costal margin with a green longitudinal stripe, snow-white below it from before the cell-end to the submarginal line, strewn with brown and green towards the costa, bordered below by a fine black line; below and behind it the wing is dark green, traversed by the undulate-dentate black submarginal line. Hindwing reddish-brown, darker violettish-brown at the margin. French Guiana.

N. folia Jones. Forewing brownish ochre mixed with green and strewn with black and brown, black *folia*. at the base with green hair; behind the indistinct anterior transverse line follows a dark shadow forming a spot in the cell; a very dark postmedian shadow towards the apex is much narrower above the centre, bordered distally by a dentate line. Hindwing yellowish brown. Rio de Janeiro (Corcovado).

N. forfex Dogn. (143 h). This species, described as a *Tachuda*, is one of the smallest; brownish-grey, *forfex*. partly dusted with green and strewn with brown, marked like the preceding species, with a large brown spot before the double anterior transverse line at the inner margin, a double red-brown transverse shadow behind the cell, followed by two blackish-brown spots, the upper one being much larger. Hindwing brownish, lighter towards the base. French Guiana.

N. lophocera Dyar is somewhat larger than *forfex*, with narrower wings and similarly marked as the *lophocera*. preceding species, grey with green spots, brown in the basal area at the costal margin, with black dots in the cell and spots at the inner margin, the distal transverse line quite indistinct, brownish, a blackish subapical spot behind it at the costal margin. Hindwing greyish-brown, lighter towards the base. Expanse of wings: 44 mm. Panama.

N. longicornis Fldr. (= *picta* Dogn.) (143 h). Basal half of forewing greyish-green, white behind it, *longi-* brownish at the apex, with double antemedian and median transverse lines, and rusty yellow spots between *cornis*.

- griseescens*. them. Hindwing whitish-grey, veins and margin brownish. — f. *griseescens* Dogn. lacks the rusty yellow colour on the head, collar and metathorax, and at the inner margin of the forewing. Expanse of wings: 43 mm. French Guiana.
- ocellata*. **N. ocellata** Rothsch. (143 i) is presumably the most gaudy species. Forewing brown, with red-brown, reddish-yellow and violet transverse striae, a red-brown transverse shadow in the centre, and two violettish-pink lines at the end, followed by a light blue spot, with 3 or 4 dentate dark transverse lines; a round velvety black subapical spot looks like an eye in a reddish-yellow corona, a submarginal row of small slaty blue spots. Colombia, Guiana, Peru.
- scintillans*. **N. scintillans** sp. n. (143 i). Palpi brownish black; head and thorax deep blackish-brown, intermixed with silvery blue scales and hairs, abdomen dark greyish-brown, darker analwards with single silvery blue hairs; ventrum yellowish-grey. Forewing deep brownish-black, strewn with silvery blue, with velvety black markings consisting of a thick oval spot in the base of the cell and longitudinal stripes as far as the antemedian line which is situated almost in the centre and is undulate-dentate, followed by a twice as thick black dentate line between the costal margin and vein 2; behind it there is an irregular reniform macula, followed by the indistinct postmedian line which extends obliquely towards the anal angle between veins 3 and 1; the notched subterminal line is shaded dark red-brown inwards; a blackish-brown submarginal dentate line forms two thick black lunular spots bordered with silvery blue outside, between veins 2 and 1. Hindwing blackish-brown, yellowish-white basally and at the inner margin. This uncommonly beautiful species was captured by WERNER HOPP on the Rio Dagua (West Colombia), at an altitude of 1000 m, in May. Type in the Berlin Museum. Veins 7, 8 and 10 of forewing not stalked.
- squamosa*. **N. squamosa** Btlr. (143 i) forms the transition to the next species; forewing greyish-brown, transversely irrorated dark especially behind the centre of the costal margin, with very indistinct transverse lines, only the very deep notches of the anterior one are somewhat more distinct; from a lighter reniform macula at the cell-end a light longitudinal patch extends into the apex; undulate line irregular, lighter, shaded with dark inwards; feeble dark internerval dots before the margin, a larger round black subapical spot. Hindwing brownish-grey. Brazil.
- virgula*. **N. virgula** Fldr. (143 i). Forewing densely dusted with steel-black and violettish-red on the yellowish-grey ground; thus the ground-colour remains only below the lower cell-end and at the apex and it is connected with a basal spot below the median vein, forming a longitudinal patch which traverses the whole wing as far as below the apex; all the other markings are rather indistinct except a very pointedly notched anterior and a flatly undulate posterior transverse line; the latter is followed behind the cell by a black lunula, with a red-brown lunula above and below it, with fine white vein-dots below the centre. Hindwing yellowish, grey at the margin. Larva exactly like a *ziezac*-larva, grey with longitudinal lines directed obliquely forward below, and slender humps, the two posterior ones of which are orange-brown like the last segment; it lives on oaks. Most widely distributed from Mexico to Argentina and Paraguay.
- superciliosa*. **N. superciliosa** Gn. (143 i) is also very widely distributed and common, coloured somewhat like *virgula*, but larger and with broader wings, without the light longitudinal patch, transversely watered with numerous fine black and brown postcellular lines, with a black dot in the lower cell-angle. Mexico to Brazil and Colombia.
- drucei*. **N. drucei** Schs. (= *sabella* Dre., part.) (143 i) has light grey forewings, darker in the basal half, and with scanty darker transverse striae; the double black median line is most distinct below the cell; its interior portion is stronger, the posterior transverse line is dentate, with black vein-dots behind it; a small reniform macula, finely surrounded with dark, is at the cell-end, a black lunar line is before the margin. Hindwing whitish, smoky at the margin. Panama.
- nyseus*. **N. nyseus** Cr. (= *guttiplena* Wlr.) (144 a) is one of the best known species of a wide range. The whitish-grey ground of the forewing often shows a violettish-blue tint, dusted with red-brown, especially at the inner margin and subterminally, densely strewn with white and black on the veins, with indistinct double transverse lines which begin with intense red-brown double streaks at the costal margin, with a thicker black short transverse streak in the median line below the cell, black and white vein-dots behind the postmedian line, and 3 black dots below each other in the long narrow reniform macula which is basally extended into a fine streak. Head and thorax ochreous, hindwing iridescent diaphanous whitish, with a broad brownish-grey band at the margin. A most variable species from Mexico to Brazil. — f. **collaris** Schs. (144 a) has a dark brown or blackish-brown head and prothorax. Described from Costa Rica, but some specimens are also from Mexico.
- quaesita*. **N. quaesita** n. sp. (144 a) is very similar to *nyseus*, but it has much narrower wings of a yellowish-grey ground-colour without any violettish-grey tints and without the blackish-white irroration of the veins, whereby it is much more regularly marked; the red-brown inner-marginal colouring is entirely absent and is only feebly visible in the interior border of the light subterminal line; all the transverse markings are very feebly darker yellowish-grey, the brown double beginnings at the costal margin finer and more distinct, the black transverse spot below the centre of the cell is very prominent, also two spots below and above vein 3 in the

centre of the treble postmedian line; the distinct and small steel-black submarginal spots of the preceding species are much larger here, but of a duller colour. Hindwing yellowish-grey with a broad dark marginal band, not whitish, iridescent. Head and prothorax light yellowish ochre. According to 1 ♂ from Misantla (Mexico), taken in June 1809; type in the Coll. DRAUDT.

N. discalis Schs. (144 a) resembles very light whitish-grey specimens of *nyseus*, with finer and clearer *disca* markings, especially the reniform macula is composed of a very fine black line shaped like a triangle with a fine appendage towards the base. Hindwing much darker, only a small basal area somewhat lighter. Costa Rica.

N. kayei Schs. (144 a) is likewise allied to the preceding species, but smaller, darker, more intensely mixed *kaye* with brown, and more extensively reddish-brown at the inner margin, with a black transverse spot in the centre of the cell, a brown line bordered with black behind it; a double row of white dots behind the postmedian line; a large irregular spot surrounded with grey is at the cell-end; the black undulate line is strongest at the interior angle, before which, at the costal margin, there is a large reddish-yellow spot enclosing a velvety black streak. The whitish hindwing is brownish-black in the distal half. British Guiana. — f. **flavescens** Dogn. shows a *flavescens* brownish ochreous ground-colour strewn with olive with markings of the same colour, excepting the lighter yellow subapical spot with a very distinct black streak in it. Brazil.

N. striata Schs. (144 b). Forewing dark violet-brown with a silky gloss, darker brown internerval *striata* streaks, the threefold transverse lines are only distinct at the margins, an irregular brown spot is in the cell-end; a long light brown subapical spot, striped reddish, is at the costal margin. Hindwing brownish-grey, lighter towards the base. Costa Rica.

N. inchoans Wkr. (144 b) is very similar to *striata*, but much smaller and of a duller greyish-brown *inchoans* colour, the inner margin of the same colour, not lighter reddish-yellow; the beginnings of the threefold transverse lines are more distinct at the costal margin, the other scheme of markings is the same; the light, oblong, apical costal-marginal spot is not defined inwards, but gradually vanishes in the somewhat lighter costal-marginal area; submedian fold brown, narrowly edged with yellowish-white on both sides. Hindwing much more extensively whitish, narrower brownish-grey at the margin. Panama (Chiriqui).

N. analeptis sp. n. (144 b) is also allied to the preceding species. Forewing much lighter red-brown, *analeptis* especially light in the inner-marginal half, scantily strewn with black and white on the veins, with somewhat darker stripes between them; transverse markings only visible at the costal margin, very long pointed dents of a reddish-brown antemedian line are very feebly marked in the inner-marginal area; the basal half of the costal margin is very dark brown, it encloses, 3 mm behind the base, a very conspicuous yellowish-white longitudinal spot of 3 mm length; a black dot behind the lower cell-angle and double black antemarginal dots. Hindwing light yellowish greyish-brown, somewhat darker at the margin. According to 1 ♂ in the Senckenberg Museum; habitat unknown.

N. arimathea Schs. (144 a) differs considerably from the other species and copies certain species of *arimathea*. *Dasylophia*; forewing cinnamon-reddish with a yellowish tint, a fine dark line on the distal half of the median vein, and a black dot at the origin of vein 2; the cell is shaded darker, a curved whitish postmedian shadowy stripe is edged with ochre distally, another fine white line farther towards the margin, the apex behind it blackish-brown, traversed by a chestnut brown line edged with reddish-yellow inside, with whitish-grey outside. Hindwing greyish-white, broadly darkened at the margin. A small species from French Guiana.

13. Genus: **Pentobesa** Schs.

Rather near to the preceding genus and chiefly separated by the longer abdomen with a bipartite fish-tail at its end. Head behind with a tuft of hair-scales; vein 5 of forewing arises from the centre of the cross-vein. Only 2 species are known:

Type of genus: *P. xylinoides* Wkr.

P. xylinoides Wkr. (= pinna Drc.) (144 b) is a well known and very widely distributed species of a most *xylinoides* variable colouring. The light yellowish-grey ground-colour of the forewing shows more or less a reddish tint and is strewn with brown, especially in a longitudinal shadow through the centre; below and above it the ground-colour is purest; rather indistinct double dentate antemedian and postmedian transverse lines are filled with light, a blackish dot is in the lower cell-angle. Hindwing yellowish-grey. Tegulae whitish-grey, mesothorax red-brown. The ♂ exhibits an area of modified scales in the lower half of the median area. From Mexico to Brazil and Colombia.

P. valta Schs. (= placida Schs., roberto Dyar) (144 c) is smaller than *xylinoides*, lighter, greyer, scantily *valta* strewn with black, without the transverse lines, instead of which there is a subterminal row of black dots, the black discal streak is very prominent. Hindwing white, narrowly smoky at the margin. Mexico to Colombia.

14. Genus: **Heorta** Wkr.

Distinguished from the preceding genus by the shorter and broader wings with a rounded distal margin and sharp apex; the neuration is the same as that of *Pentobesa* except vein 6 arising a little above the upper cell-angle from the accessory cell, and besides the costal branch of the hindwing arises from the centre of the subcostal branch; in *Pentobesa* farther at the cell-end.

Type of genus: *H. roseoalba* Wkr.

roseoalba. **H. roseoalba** Wkr. is a pure white insect, the marginal area is slightly tinged with pink, the veins finely striped pink, and two notched broad pink transverse stripes, the anterior stripe is distally angular in the cell and on the submedian fold. Hindwing white with pink fringe. This pretty and considerably deviating Notodontid species has been described from Brazil.

cilla. **H. cilla** Dogn. (*oculata* Dogn., *mitis* Schs.) (144 c). The olive green ground-colour is dusted with red-brown in some places, the ♂ is more intensely strewn with black, with double black transverse lines, the posterior one being dotted white: a blackish oblique shadow extends from before the centre of the costal margin towards the anal angle which it does not reach, stopping before a thick black dot. Hindwing greyish-brown, lighter and more yellowish towards the base. Colombia, Bolivia, Brazil.

viridans. **H. viridans** Dogn. (144 c) is very similar to *cilla*, slightly larger on an average, with broader wings, lighter olive green, less intensely strewn with dark, with more scanty and finer markings, so that the black dot above the anal angle is more conspicuous. Hindwing somewhat lighter. Bolivia, Brazil.

carema. **H. carema** Schs. is smaller than *viridans*, the reddish-yellow ground is mixed with olive green and shows a large triangular brown area mixed with lilac, green and white, edged by the two velvety brown double transverse lines which are united above the centre of the inner margin; two dark brown spots are before the upper distal angle of this area; a black subterminal shadow is dusted with white distally. Hindwing dark brown. Expanse of wings: 27 mm. French Guiana.

15. Genus: **Theroa** Schs.

This genus had been originally established for the only species *zethus*, but it was cancelled again, and *zethus* ranged with the genus *Litodonta*; I leave the genus in its original form and range *zethus* as the type of it. Vein 6 of the forewing arises from the upper cell-angle, in *Litodonta* from the centre of the areole; the two lower subcostal branches arise on a rather long stalk from the end of the areole; vein 5 arises far above the centre of the cross-vein, about midway between the upper cell-angle and the centre of the cross-vein, in *Litodonta* rather exactly from the centre of the cross-vein. The lower larger half of the cell is quite open, only the upper short portion is closed and extends rectangularly to the subcostal vein; the costal vein arises directly from the upper cell-angle; vein 3 arises separated from 4, 5 is very feeble, 6 on a long stalk with the subcostal vein. The cross-vein on the hindwing of *Litodonta* is closed altogether, although the lower, very oblique part is feeble, the costal branch arises far before the cell-end. Only 1 species:

Type of the genus: *Th. zethus* Drc.

zethus. **Th. zethus** Drc. (144 c) is light whitish lilac grey on the forewing, strewn with brownish, the two median transverse lines are marked by rows of vein-dots edged with whitish, a red-brown reniform macula centred with reddish-brown is at the cell-end, and an antemarginal row of small red-brown internodal spots edged with reddish-yellow distally, then narrowly with red-brown. Hindwing of ♂ whitish, smoky at the margin, of ♀ brownish-grey, somewhat more whitish towards the base. Mexico.

16. Genus: **Euhyparpax** Beut.

This genus contains but one North-American species the ♂ of which has the antennae not pectinated to the tips and very short palpi. Forewing very slightly concave in the middle of the costal margin, the areole is very narrow and short, the other neuration very similar to that of *Heorta*. The costal branch of the hindwing arises near the cell-end. Only one typical species.

Type of the genus: *E. rosea* Beut.

rosea. **E. rosea** Beut. (144 c) is easily recognizable by yellowish pink forewings with a very indistinct darker curved postmedian line; traces of a yellowish spot are at the cell-end. Hindwing pink with lighter fringe. This rare species is only known from Colorado so far.

17. Genus: **Bardaxima** Wkr.

Antennae of ♂ tuftedly ciliated, the third joint of the palpus long. Distal margin of forewing dentate; areole long and narrow, the two lowest subcostal branches not stalked from the end of it.

Type of the genus: *B. lucilinea* Wkr.

B. lucilinea Wkr. (= *fulgurifera* Wkr., *demea* Drc.) (144 d) is a large, common and well-known species *lucilinea*. with greyish-brown forewings which are transversely irrorated in a darker colour, a jet-black longitudinal streak on the discal fold extends to the margin and is interrupted in the middle by a silvery white streak; a dark brown posterior transverse line is more or less completely marked, above the inner margin, near the base, there is a brown spot which is distinctly bordered by a twice angular velvety brown line distally; a spot of whitish clouding is above the anal angle. Hindwing brownish-grey with lighter yellowish fringe. Mexico to Brazil and Bolivia.

B. hippoides Schs. is much smaller than *lucilinea*, dark violet-brown, dull brown towards the base, a *hippoides*. short, dark velvety brown streak edged with white below the cell near the base, a greenish spot behind it before the brown anterior transverse line; a dark velvety brown lunar spot is in a brown spot at the cell-end, a similar, wedge-shaped spot behind it, a white streak above the latter spot along vein 5, bordered by a short white line, both bordered by dark brown, the apex is parted by a light brown oblique shadow. Hindwing brownish-grey. Expanse of wings: 45 mm. Costa-Rica.

B. perses Drc. (= *demera* Schs.) (144 d). Forewing grey, shaded with brown subterminally and at the *perses*. costal margin, with darker grey double transverse lines, the posterior one with lighter spots bordered with black, followed by a series of black spots; a velvety black strigiform spot at the cell-end, a grey spot below it; a black strigiform spot is in a whitish apical spot which turns reddish-brown distally. Hindwing brown with lighter fringe. Guiana, Amazons.

B. belua sp. n. (144 d) is a large species with broad wings; the whitish ground-colour of the forewing *belua*. is reddish-violet at the inner margin and behind the lower cell-end, otherwise light green, broadly dusted with olive green and strewn with blackish at the costal margin, the double transverse lines are blackish, undulate-dentate, rather inconspicuous; a blackish-brown crescentiform spot is at the cell-end, before it, from the costal margin, a broad curved olive green shadow which extends to vein 2 down to the posterior transverse line, behind which — between the costal margin and vein 4 — a broad blackish-brown shadow is situate, forming a broad distal concavity between 5 and 7, a greyish-brown spot is below it before the undulate-dentate subterminal line; the anal-marginal half is purer whitish. Hindwing greyish-brown, fringe whitish, speckled blackish-brown on the veins of the forewing. Abdomen brownish-grey with a broad light grey dorsal stripe. 2 ♀♀. 1 ♂ from Pachitea, Eastern Peru, and Santarem. Types in the Berlin Museum.

B. molossus Rothsch. is a very large species, peculiar for the double preapical excision of the costal margin *molossus*. of the forewing; forewing greyish-brown, densely transversely striated darker, the distal three fifths of a more yellowish tinge, the striae arranged in such a way that, especially in the distal half, they make the impression of dentate transverse lines; a double, slightly bent blackish-brown median line extends through the centre; a large chestnut-brown subapical spot. Hindwing greyish-brown with lighter fringe. Expanse of wings: 73 mm. Amazons.

B. marcida Fldr. (144 d). Forewing dark brownish-grey, dusted with white behind the centre towards *marcida*. the inner margin, with double dark transverse lines, the anterior line strongly curved, the posterior line dentate, with a black cellular dot and discal streak. Hindwing greyish-brown with lighter fringe. Colombia and Brazil.

B. terminalba Jones (144 e). The brownish ochreous forewing dusted with dark grey is greyish-white *terminalba*. at the base and in the lower two thirds of the marginal area; the double transverse lines are reddish-brown, the anterior line is darker; a subterminal row of black internodal dots, and two short black streaks at the cell-end. Hindwing yellowish-brown. South-Eastern Brazil.

B. dissona sp. n. (144 e) has narrow wings. Basal area of forewing narrowly yellowish-grey, spotted *dissona*. reddish-yellow towards the black defining subbasal line, a glaring silvery white crescentiform spot distally bordered with black behind this line below the cell; light greyish-brown and irrorated with blackish-brown as far as the posterior transverse line, a reddish-yellow spot behind the anterior transverse line at the costal margin, a black streak at the cell-end; posterior transverse line black, undulated, projecting far distally behind the cell; the distal part of the wing is densely strewn with brownish-black on the white ground, a black lunular line before the margin. Hindwing greyish-brown. 1 ♂ from Iquitos; type in the Berlin Museum.

18. Genus: **Phedusia** Mschlr.

Distinguished by uncommonly long antennae which may be almost as long as the forewing, provided with terminal bristles in the male; palpi long, also the third joint, and densely clad with short hair. The long abdomen exhibits an anal tuft; the legs, inclusive of the tarsi, are densely haired. Neuration of forewing like

that of the preceding genus, but vein 5 arises much nearer at 6; the cell of the hindwing despatches all its branches without a stalk. Only two species are known.

Type of the genus: *P. turbida* *Mschlr.*

turbida. **P. turbida** *Mschlr.* (= *apicenotata* *Dogn.*, *castaneobrunnea* *Rothsch.*) (144 e) has yellowish-brown forewings densely strewn and dusted with red-brown, with indistinct double transverse lines and a greenish spot before the anterior one below the cell; a double reniform-macular streak at the cell-end is closed above, a large dark red-brown subterminal crescentiform spot near the costal margin encloses black longitudinal striae, a small light reddish-yellow subapical spot at the costal margin is bordered with deep velvety brown distally. Hindwing dark brown. Guiana.

riachuela. **P. riachuela** *Jones* (144 e) is much smaller than *turbida*, brown, with double darker transverse lines filled with ochre, the posterior line quite indistinct, the upper distal half of the median area strongly darkened in a triangular shape, enclosing 2 yellowish-white triangular spots which are similarly shaped as in the very well-known *Didugua leona* (146 a), but somewhat larger. Hindwing brown with lighter fringe. Brazil, Bolivia.

19. Genus: **Elymiotis** *Wkr.*

Structure very similar to that of the preceding genus, but with shorter antennae and also shorter palpi. Neuration almost the same, but vein 5 arises somewhat deeper, but above the centre of the cross-vein.

Type of the genus: *E. notodontoides* *Wkr.*

notodontoides. **E. notodontoides** *Wkr.* (= *sericea* *Wkr.*, *phaleroides* *Wkr.*) is similar to the two next species, but considerably larger; forewing somewhat more brownish, without the intense transverse speckling, the double dentate transverse lines are more distinct; the black transverse streak below the cell is absent, but there is more blackish shading in the median area; a plain reniform macula in a somewhat lighter ring is in the cell-end, followed by dark longitudinal lines between the darkened veins; the silvery white longitudinal streak is absent. Hindwing greyish-brown. Brazil.

attenuata. **E. attenuata** *Wkr.* (= *ancora* *Fldr.*) (144 e) is a very common, widely distributed species with greyish-brown forewings with darker transverse speckling, indistinct double dentate transverse lines which begin more distinctly and very obliquely at the costal margin; a very characteristic jet-black transverse streak below the cell is slightly interrupted by the submedian fold and bordered on both sides by erect, partly lighter scales; one black dot in a somewhat lighter ring at each cell-angle, some fine blackish-brown longitudinal lines behind it, the lowest being interrupted in the middle by a silvery white longitudinal streak which bifurcates a little distally. Hindwing greyish-brown. Mexico to the Amazons.

corana. **E. corana** *Schs.* (144 f). This species is found in the collections partly as *longara* *Stoll* which, according to the figure and description, has pectinated antennae, or as *attenuata* *Wkr.*, or *ancora* *Fldr.*, both of which are smaller species. Forewing silvery greyish-brown, the markings blackish-brown; transverse lines double, the anterior one angled on the median vein, where it is defined inwards, with erect velvety black scales as far as vein 1; a velvety black spot in the lower cell-angle, a smaller one above it farther outside; median vein and vein 4 shaded with dark above, with whitish beneath; a small triangular white postmedian spot between 4 and 5; marginal area between 4 and 6 brownish-grey, veins 5 and 6 and the space between them, as well as above and below them striped black; a black undulate-dentate line before the margin. Hindwing brown, lighter towards the base with white fringe and a small double anal spot. The ♀ is more monotonously greyish-brown with less prominent marking. Expanse of wings: 48—54 mm. Mexico to French Guiana.

alata. **E. alata** *Drc.* (144 f) is differently coloured and marked; smaller and lighter coloured, especially the inner-marginal area is lighter, more yellowish, less marked, all the transverse markings finer, the black antemedian streak below the cell distinctly double; a distinct whitish patch before that streak to the base; the light forked longitudinal streak in the lowest longitudinal line before the margin is not white, but contrasts only slightly with the yellowish ground-colour, another similar streak is above it. Hindwing greyish-brown with light yellowish fringe. Distal margin of forewing less strongly notched. Honduras, Panama.

purpurascens. **E. purpurascens** *Btlr.* (144 f) is very similar to *attenuata*, but decidedly darker and more red-brown on the whole, the black antemedian streak below the base is much less prominent, the fine longitudinal linear marking in the subterminal area is less pronounced owing to a dark brown shadowy blotch above it; the lower one of the two discal dots is much thicker, spot-shaped and in a distinct lighter ring, the posterior transverse line is more distinct, more spotted, especially strong at the costal margin. Hindwing darker brown. From Panama to the Amazons.

plechelm. **E. plechelm** *Schs.* is somewhat similar to *purpurascens*, from which it differs in the absence of the white forked longitudinal streak: the ground-colour is more cinnamon reddish grey, but much lighter, Isabel-coloured

on the median vein, in a basal area below the cell, in a spot below the lower cell-angle and along the costal margin, the shadow behind the cell as far as the margin purple brown, a whitish line dusted orange is subapically above it. The hindwing is white in the basal half, cinnamon-brown with a bronze gloss outside, with white fringe. Peru.

E. audax *Drc.* is much lighter yellowish bay on the forewing, yellowish at the inner margin, the black *audax*. spot at the lower cell-end very large, the transverse line behind it composed of black dots; the cell is traversed by a white longitudinal streak; otherwise similarly marked as *plechelm*. Hindwing light yellowish-brown, darker outside. Expanse of wings: 40 mm. Described from Panama.

E. morana *Schs.* (144 f). Head and thorax red-brown, abdomen brownish-grey. Forewing brownish *morana*. sand-coloured, the base and the discal veins strewn with greenish and black, light greenish scales are also below the distal half of the cell; transverse lines double, the anterior one velvety black, interrupted below the fold, a triangular dark shadow before the middle line in the lower half; a round velvety black spot is in the lower cell-angle and a smaller streak bordered with white above towards the base, and a vertical streak above it; a black longitudinal line with a fine short silvery white Y-mark extends through the cell and behind it; the double posterior transverse line is brown, filled with a lighter colour, a white line is before it at the inner margin; blackish-brown subterminal streaks above 5 and 6. Hindwing brown, whitish towards the base with a small double anal spot. Expanse of wings: 42—50 mm. Mexico to French Guiana and Colombia.

E. glaucula *sp. n.* (144 f). Head, collar and mesothorax rusty yellowish, tegulae light violet-grey, border *glaucula*. of collar and metathoracal tuft more blackish-brown; abdomen brownish-grey. Forewing brownish-grey in the basal half — in the anterior half as far as the cell-end, below the median vein only as far as the strong antemedian double streak — covered with light greenish-grey scales behind the subbasal area, the distal half of the wing light violet-grey, more greenish at the costal margin and in the proximal half of the median area; a whitish patch behind the submedian red-brown double streak; the two black fine dots at the cell-end, a fine black longitudinal streak between these dots extends to the very fine arcuate submarginal line, interrupted on the posterior undulate-dentate transverse line, but not white; a double row of black dots behind the transverse line; subterminal line feebly shaded with rusty brown inwards; fringe rusty brown. Hindwing light brownish, broadly darkened at the margin. Type: 1 ♀ from Mexico (Colima) in the Coll. DRAUDT; 1 ♂ from Guatemala in the Berlin Museum.

E. lupicina *Schs.* Forewing light brownish-grey, the veins strewn with black and white, double undulate *lupicina*. transverse lines, a whitish brightening behind the anterior line between the cell and the inner margin; a short vertical line before the median line is composed of erect velvety black scales, with an appendage towards the base on the fold; a large round velvety black spot; in the lower cell-angle, and a smaller one above it; the posterior transverse line is punctiform with an indistinct undulate line behind it between the costal margin and 5, and a triangular silvery spot between 5 and 4; blackish-brown velvety subterminal spots below 7 and 6, and a large duller spot below 5 at the silvery spot. Hindwing white, veins and margin brown with an anal double strigiform spot. Expanse of wings: 39 mm. Paraguay.

E. donatian *Schs.* Head and shoulders whitish, thorax brown, abdomen brownish-grey. Forewing *donatian*. brownish cinnamon-coloured, suffused with grey, basal area and costal margin lighter; a vertical velvety black antemedian line between the cell and the inner margin; median line in the cell light brown, silvery white scales behind it above the median vein as far as the cell-end, a small black spot on the cross-vein; end of median vein black, continued along 5 as far as the margin, interrupted by a silvery white streak behind the double postmedian line, a brown shadow behind the latter between the cell and the inner margin; the whole forewing is transversely striated darker. Hindwing white, narrowly brownish at the margin. Expanse of wings: 46 mm. British Guiana.

E. complicata *Dogn.* was described as *Gisara*, but it belongs near to *donatian*. Forewing earth-brown, *complicata*. yellowish-white in the basal and anal areas, watered violet or greenish along the costal margin, on the submedian vein and behind the cell as far as the margin, traversed by indistinct double blackish-brown transverse lines which are edged with yellowish ochre, the posterior line forms a yellowish inward point between 4 and 5, black longitudinal streaks are behind it; two black dots at the cell-end, the lower dot is much thicker, two more dots before the upper dot in the cell. Hindwing blackish, lighter towards the base, with whitish fringe and a black anal spot divided by light. Expanse of wings: 51 mm. French Guiana.

E. longara *Stoll* has not yet been undoubtedly diagnosed, but according to SCHAUS it is to be ranged *longara*. here; it almost resembles a *Dasylophia*, forewing yellowish-grey, darkened grey in the marginal area, broader towards the apex, with fine brownish double transverse lines, the posterior line surrounding the cell-end in a large bow, a fine black dot in its lower angle; veins finely striped darker, dark longitudinal streaks between them in the marginal area. Hindwing brownish-grey. Surinam.

E. cretosa *Dogn.* Forewing light yellowish, strewn with red-brown, with double chestnut-brown trans- *cretosa*. verse lines proceeding from intense costal-marginal streaks, a black double streak at the end of the cell which is dusted with brown; the double subterminal line filled with white forms a bow from near the apex to the anal angle, one white dot or streak each is before and behind it. Hindwing red-brown, base and fringe yellowish-white. Expanse of wings: 46 mm. Ecuador.

boisil. **E. boisil** Schs. Head and thorax blackish-brown, only the collar and metathorax brownish cinnamon-coloured. Forewing light brownish cinnamon-coloured; dark undulated double antemedian lines, a thick velvety black line behind them at the inner margin, bent up to the cross-vein and extending along 5 almost to the margin, where two small black spots are above it; the line has yet a triangular continuation downward across the median fold, and a tiny silvery white spot near the end with a continuation towards the base; discal veins strewn with black and white; white marginal dots on the ends of the veins. Hindwing white, broadly cinnamon-brown at the margin. Expanse of wings: 45 mm. French Guiana: Amazons (Teffé).

20. Genus: **Ctianopha** Schs.

Structure like that of *Elymiotis*, but with broader wings which show a distinct angle at the somewhat dentate distal margin on vein 3. The second joint of the palpus is longer than in *Elymiotis*, and the collar exhibits tufts of scales. The neuration is the same, but vein 6 of hindwing is always more distinctly stalked with 7. 4 species are known so far.

Type of the genus: *C. argyria* Btlr.

argyria. **C. argyria** Btlr. is similar to the species of the genus *Calledema*; forewing reddish-brown, with indistinct darker double transverse lines, a dark dot at the cell-end in the lower angle, a silvery stripe extends from this dot to the centre of the distal margin and cuts the lighter undulate linear shading which comes down in 3 inwardly curved bows; the latter shading despatches downward three branches to the 3 lowest marginal veins. Hindwing brownish-grey. Brasil.

argenti-linea. **C. argenti-linea** Schs. is yellowish bay on the forewing, strewn with darker brown, dusted with green at the costal margin, in the distal half of the cell and in a spot before the centre below the cell; transverse lines marked darker; a streak on the distal half of the median vein and the cross-vein are silvery white, a submarginal row of black spots, brown internerval streaks on the margin. Hindwing red-brown, lighter towards the base with a black anal spot which is parted by white. Expanse of wings: 32 mm. French Guiana.

serena. **C. serena** Schs. is similar, with the same green spots, but the ground-colour is lilac grey, only the brown cross-vein is narrowly bordered with silvery white outside, with yellow inside; the transverse lines are much less distinct, only formed of darker strewing; a brown spot is before the lowest black submarginal spots. Hindwing as in *argenti-linea*. Expanse of wings: 32 mm. British Guiana.

lilacina. **C. lilacina** sp. n. (144 g). Forewing light lilac grey, strewn with blackish-brown, double undulate-dentate transverse lines are marked by denser strewing, the posterior line is followed by black and white vein-dots; a narrow, brownish-grey reniform macula bordered with white is at the cell-end, a darker spot before it in the cell; dense blackish-brown strewing before the undulate line; a fine light crescentiform line in the marginal area which is more densely strewn with blackish-grey. Hindwing greyish-brown, a black spot parted by white is at the anal angle. 1 ♂ from Thomar: Berlin Museum.

21. Genus: **Proelymiotis** Schs.

Separated from the closely allied *Elymiotis* by a very high tuft of hair-scales on the frons; palpi porrect, with a longer middle joint. The neuration scarcely differs from that of the two preceding genera. A number of species with a very different exterior have been described.

Type of the genus: *P. aequipars* Wkr.

aequipars. **P. aequipars** Wkr. (= *seminiva* Wkr., *divisa* Mschlr.) (144 g) is a very characteristic, common and widely distributed animal with yellowish whitish-grey forewings, dark blackish-brown in the basal half and a costal spot behind the centre, the distal portion traversed by numerous double fine dark transverse lines; a finely margined irregular reniform macula; small slate-black spots before the margin. Hindwing brownish, dark brown on the margin and veins. Mexico to Peru and Brazil.

similis. **P. similis** sp. n. (144 g) is exceedingly similar to *aequipars*, easily discernible by the white, thinly scaled hindwings with a narrowly smoked margin and veins; basal area mixed with a somewhat lighter reddish-brown colour, the border-line distally extending more vertically to the inner margin; distal area purely silvery white, scantily strewn with blackish, with a narrow reniform macula which shows three distal notches, at the cell-end; a fine notched white subterminal line is before the very distinct fine black submarginal line, fine black pointed arrow-shaped spots are on its proximal side, similar pointed spots are before the fringe, the points extending into the fringe. 1 ♂ from Petropolis, type in the Berlin Museum.

severina. **P. severina** Schs. Frons white, spotted black, thorax black except the collar, which is cinnamon-brown in front, and the similarly coloured basal tuft of the antenna. Basal half of forewing of a deep slaty brown

colour, the black linear markings in it are finely edged with a brownish sand-colour, costal margin black with a fine double white antemedian line; a small reddish cinnamon spot at the inner margin in the dark basal part; distal half reddish, turning cinnamon-brown at the margin, an oblong brownish-black spot at the costal margin, from a black dot before it a reddish-yellow line extends to the inner margin; 3 fine indistinct postmedian lines, the first undulate-dentate, all of them with dark vein-dots; subterminal line whitish, edged with cinnamon-brown, a small dark spot behind it at the anal angle. Hindwing reddish-yellow, apex and margin suffused with a brownish cinnamon-colour, with a small dark anal spot. Expanse of wings: 63 mm. Brazil (Rio Purus).

P. nystalina *sp. n.* (144 g). Wings shaped exactly like those of *Nystalea*, but according to the neuration *nystalina*. it is a *Proelymiotis*. Head and thorax light reddish yellowish-brown; collar light dove-coloured, abdomen brownish-black, creamy beneath. Forewing light dove-coloured at the base, in the distal half of the costal margin and in a broad transverse band through the cell-end, the rest reddish-yellow, with extraordinarily high pointed notches of a red-brown double antemedian line; double red-brown transverse lines before the cell-end border on the light grey median band, a narrow reniform macula feebly filled with yellowish, a blackish line above it and below it; the grey band is distally defined by a thick double red-brown line, black-white vein-streaks are behind it and oblique slate-coloured internerval streaks before the margin. Hindwing scantily covered with whitish scales, veins and margin smoky. 1 ♂ from Blumenau (Brazil), type in the Senckenberg Museum.

P. lignicolor *Mschlr.* (= *exusta* *Btlr.*, *arpia* *Schs.*) (144 h). Colouring and marking very similar to that *lignicolor*. of certain species of *Dasylophia*, as which it was also described. Forewing brown, mixed with olive yellow, inner margin yellowish-white, a dark brown longitudinal stripe above it extends to the margin in a double bow; the clay-coloured area extends between the lower radial branches to the margin, a round blackish-brown spot is below it near the anal angle, the margin is darkened grey in some places. Hindwing brownish-grey, darker at the margin with yellowish fringe. Guiana to Brazil.

P. lavana *Dogn.* is very closely allied to *lignicolor*, the forewing is more light brown, the median area *lavana*. partly shows a reddish pink tint, grey dusting is at the cell-end and behind it, brown at the end of the median vein and below it; brown spots are behind the undulate line, followed by white striae which extend less high towards the costal margin in *lignicolor*. Hindwing blackish, lighter towards the base, with whitish fringe. Expanse of wings: 37 mm. French Guiana.

P. xylophasioides *Btlr.* (144 h) is allied to the two preceding species; forewing bone-coloured white, *xylopha-* striped reddish-brown on the veins and between them, darkened somewhat greyish-brown at the inner margin, *sioides*. the characteristical dark brown longitudinal stripe above it; a contrastingly red-brown undulate linear shading is before the light bluish-grey margin, terminating before the anal angle, where it is replaced by a large, black spot which is encircled with white and yellow. Separable by much lighter, dingy white hindwings. Brazil.

P. joanna *Schs.* (144 h). Forewing grey, reddish-yellow in and behind the cell, the inner margin and *joanna*. distal margin light brown, with darker spots in the centre of the costal margin, at the apex and below the centre of the distal margin; transverse lines double, the two anterior ones indistinct, the posterior one dark brown, filled with a lighter colour; the light brown hindwing is violet-brown at the distal margin, fringe yellowish. French Guiana.

P. serrata *Schs.* Forewing reddish-yellow in the basal half, dusted with brown at the base and margins, *serrata*. with fine grey veins, grey behind them, the darkest area below the cell-end, cross-vein striped white; a fine reddish-brown line before the brown median line, a blackish-brown line behind it; the fine undulate blackish-brown posterior transverse line is followed by a reddish-yellow shadow with black and white vein-dots; the white undulate line is darkened above the centre by dark shading. Hindwing greyish-brown with whitish fringe. Expanse of wings: 42 mm. Guatemala.

P. manacoides *Schs.* Forewing lilac brown. Basal area and basal half of cell white strewn with brown; *mana-* white are besides: a basal streak above the submedian line, the anterior transverse line with a blackish-brown *coides*. cellular spot before it, finally a short thick streak behind the cell, which is continued obliquely towards the apex by a fine line; a dark brown discal shadow extends to the margin; small blackish-brown internerval spots are before the margin. Hindwing light greyish-brown. Expanse of wings: 43 mm. Guatemala.

P. argolarma *sp. n.* (144 h) has metallic brass-coloured forewings finely strewn with brown, some parts *argolarma*. being more densely strewn so that fine notched transverse lines and a narrow reniform cell-end macula are produced which are difficult to distinguish in the strewn ground; costal margin and subterminal area dusted somewhat lilac; a tear-shaped narrow silvery drop bordered with black below is behind the upper cell-angle along the middle radial branch; a fine blackish-brown, scalariformly notched submarginal line, a roundish, purely light yellow subapical spot before it at the costal margin. Wings broader than in the typical representatives of the genus. Hindwing brownish-grey. 1 ♂ from São Paulo de Olivença: type in the Senckenberg Museum.

22. Genus: **Lysana** *Mschlr.*

Distinguished by a long hair-tuft at the base of the antenna, the long erect palpus shows a very short terminal joint, the front legs are very thickly haired. The broad forewing is entirely margined with a rounded

apex and a very slight concavity before it at the costal margin; vein 5 arises above the centre of the cross-vein, 6 from the areole, the subcostal branches from its end; the cellular branches of the hindwing are stalked by twos, the upper ones longer, the costal vein arises near the base of the cell.

Type of the genus: *plexa* *Mschlr.*

plexa. **L. plexa** *Mschlr.* Forewing reddish-brown, shaded with violettish-grey at the inner margin and distal margin, with a white eostal margin; the two broad dark brown transverse stripes are confluent above the submedian fold and together extend from here to the inner margin, producing a Y-shape; a black double dot at the cell-end; the undulate line is only marked by the contrast between the grey marginal area and the reddish interior part; dark internerval streaks are before the margin. Hindwing brownish-grey, a black spot divided by white is at the anal angle. Brazil, Guiana.

parvipuncta. **L. parvipuncta** *Dogn.* has yellowish-brown forewings with somewhat darker veins and a brown oblique line extending from the first quarter of the costal margin to the centre of vein 2, from where irregular, partly double red-brown strigiform spots run to the apex; a white triangular spot is behind the cell, its point showing towards the cell; brown internerval streaks are before the margin. Hindwing blackish with lighter fringe. Expanse of wings: 37 mm. French Guiana.

plusiana. **L. plusiana** *Schs.* (= *postpicta* *Dogn.*) (144 h) differs from the diagnose of the genus in the smoothly scaled anterior legs; a very small species, the forewing lilae grey mixed with olive brown, with an oblique white line from the submedian vein to the cell-end with a copper-brown shading behind it and a golden triangle in the centre of the inner margin, another shorter similar line below it at the inner margin; a blackish stripe extends from the cell to the distal margin, an oblique white stripe is behind it; the distal margin is brownish in the upper two thirds, mixed with eoppery. Hindwing of ♂ white with a brown margin, of ♀ quite brown. Panama; Venezuela; Guiana; Brazil (Goyaz).

minasensis. **L. minasensis** *Schs.* Anterior body white, mixed with a lighter and darker brown. Forewing reddish-yellow with a brownish einnamon-coloured subbasal line, shaded with brown below the median vein, with a fine white line extending through the cell to the base of vein 4; an olive brown double antemedian line from the costal margin to the white cellular line, another line close behind it extends to vein 1, despatching a branch to the white cellular line, bordered with white above inside and below outside; a broad olive brown shadow behind it is partly bordered with blackish-brown, distally with a short blackish-brown line to the lower cell-angle with a dark oblique streak above it, and a velvety black dot in the cell before it, bordered with white; above it, at the costal margin, there is a double olive brown line bordered with white on both sides; the double postmedian line is olive brownish; a white crescentiform line in the centre of the inner margin, and a fine blackish-brown line above vein 4 does not reach the margin; subterminal line white, spotted olive brown on vein 5 on both sides, and with oblique white, brown-edged marginal streaks below it. Fringe spotted dark. Hindwing reddish-yellow, brown at the margin, with a dark anal spot parted by silvery white. Expanse of wings: 52 mm. Minas, Brazil. Larger and lighter than *plusiana*, without its golden brown marking.

23. Genus: **Pseudantiora** *Ky.*

Antennae tuftedly eiliated as in all the preceding genera, the upturned palpi long, the second joint twice as long as the third; long hair-tufts between the antennae on the head as in the preceding genus. The neururation does not differ much from that of the species of *Lysana*.

Type of the genus: *P. contingata* *Mschlr.*

contingata. **P. contingata** *Mschlr.* (144 h). Forewing greyish-white with a slight olive tint and a straight broad blaekish-brown longitudinal stripe from the basal third of the costal margin to the centre of the distal margin, a similar trapezoid spot above it subapically, and two small spots below the centre of the cell; traces of undulate transverse lines. Hindwing light brownish-grey, darkened at the margin. Guiana to Colombia and Brazil.

rufescens. **P. rufescens** *Schs.* (144 h) resembles *contingata*, but it is easily distinguished by the lighter red-brown colour of the longitudinal stripe which widens towards the base to almost the whole width of the wing and is more distinctly separated towards the costal margin by a white line from the light grey ground-colour; another black dot between the subapical costal-marginal spot and the longitudinal stripe. The range is the same.

irregularis. **P. irregularis** *Dogn.* is likewise very similar to *contingata*, the forewing is yellowish-white, the blaekish-brown longitudinal band does not extend straightly and horizontally to the centre of the margin, but from the costal margin, where it occupies the whole basal quarter, obliquely rounded with a very irregular border to the margin between 2 and 4; the spots below the centre of the cell form a branch narrowing down towards the inner margin; another preapical eostal-marginal spot is as large as the first; blaekish-brown internerval spots on the margin. Hindwing blaekish-brown with yellowish-white fringe. Expanse of wings: 38 mm. French Guiana.

P. laurena Schs. lacks the characteristic dark longitudinal stripe through the forewing which is coloured *laurena*. white, strewn with brown, and feebly shaded with greenish at the base of the costal margin, in the cell above the median vein and above the inner-marginal vein; inner margin and costal margin brown in the centre, with numerous transverse lines, the antemedian ones composed of spots, the hinder ones of double rows of lunae, a short double postmedian line above the inner margin, before the double postmedian line there is another single line, two of its lunae above the inner margin are much stronger than the others; apex dusted brown, containing a large black spot at the distal margin, which extends down to vein 5, smaller black spots below it, being strigiform at the anal angle. Hindwing light brown, darkened at the margin, whitish in the disc. Expanse of wings: 35 mm. French Guiana.

P. indiscreta Dogn. has also white forewings densely strewn with brown, more purely white behind the *indis-* centre, with numerous irregular and interrupted double transverse lines, a dentate line behind the postmedian *creta*. line, the dents of which are particularly prominent behind the cell; opposite to them there are black internerval spots on the yellowish-grey ground, above which black shading extends to the costal margin; a longitudinal row of 7 black dots in the cell, cross-vein white, above with a black streak. Hindwing white with a black costal margin and distal margin which narrows down analwards. Expanse of wings: 40 mm. Amazons (São Paulo de Olivença).

24. Genus: **Cottobara** Wkr.

This genus and the following genera are without the vertical tuft: the ♀♀ antennae are finely ciliated, the rising palpi densely scaled with a very small terminal joint. Neuration exactly the same as in *Lysana*, but the costal branch arises near the cell-end. Only 1 species:

Type of genus: *C. concinna* Wkr.

C. concinna Wkr. is a large red-brown insect intensely strewn with whitish, the inner-marginal area *concinna*. shaded with violettish-grey; the two darker brown transverse lines are crenulate, connected by a broad dark longitudinal shadow on the submedian fold; one round dark ring each surrounded by a lighter colour is in the cell and at the end, whereby a Noctuid marking is produced; the sharply notched light undulate line is shaded somewhat darker inside and shows dark internerval streaks behind it. Hindwing dark brownish-grey with lighter fringe. Expanse of wings: 56 mm. Brazil.

25. Genus: **Marthula** Wkr.

Chiefly distinguished from the preceding genus by the longer abdomen with a fan-like or fishtail-like anal tuft in the male. The neuration differs in the vein 5 of the forewing arising from the upper cell-angle, not from the areole, and the veins 3 and 4 of the hindwing arising separately. Numerous similar species are known.

Type of genus: *M. quadrata* Wkr.

M. quadrata Wkr. (144 i) is one of the most insignificant species with brownish, darker strewn forewings *quadrata*. with 3 straight oblique lighter-edged transverse lines, the two anterior ones of which do not reach the costal margin, and a reniform macula at the cell-end above the median transverse line. Hindwing whitish with a narrow dark margin. Collar and mesothorax darker brown, contrasting with the light tegulae and head. Brazil.

M. multifascia Wkr. (= *nora* Schs.) (144 i). Markings similarly arranged as in *quadrata*, but more *multi-* gaudily coloured, forewing brown in the upper half, more lilac grey in the larger inner-marginal half, broadly *fascia*. rusty yellow or chestnut-red in the centre of the costal margin and in a spot in the centre of the distal margin. Hindwing white, brownish on the veins and margin. Brazil.

M. rufescens Schs. resembles *multifascia*, but it is at once separable by the dark, brown hindwings; *rufescens*. forewing brown, dusted with lilac basally, at the inner margin, in and below the centre of the cell, and in the lower half of the distal margin, broadly red-brown at the costal margin, without the red marginal spot, the partly double transverse lines are edged with lilac, small dark internerval spots are before the margin. The larger ♀ is more monotonously dark brown, and not red-brown at the costal margin. Expanse of wings: 35—40 mm. Costa Rica.

M. thoreda Schs. is allied with *quadrata*; forewing rusty reddish-brown, broadly suffused with brown *thoreda*. at the costal margin and distal margin down to vein 3, and also at the inner margin before the lines; the latter are fine, light reddish grey, the antemedian line double, the inner portion in the cell interrupted by a dark round spot, a smaller cellular spot behind the exterior portion; the oblique reniform macula is long and narrow surrounded by light; small black subterminal lunules. Hindwing brown, whitish in the disc. Expanse of wings: 37 mm. French Guiana.

M. cynrica Sch. is similar to *hirsuta*, genitally different. Forewing light reddish grey in the median *cynrica*. area and at the margin downward from vein 3, the margin above it and the costal-marginal area suffused with

orange; the lines are shaded with deep brown inside in the lower half, subterminally with narrow black internerval streaks, bordered with light distally. Hindwing white. veins and margin cinnamon-brown. Expanse of wings: 34 mm. Guatemala.

pleione. **M. pleione** Schs. (144 i) is at once recognizable by the two large yellowish-white costal-marginal spots reticulately marked with red-brown lines, the basal spot being smaller than the one situate in the centre of the costal margin; the inner margin of the brown forewing is broadly dusted with grey; the other marking is the same as that of *cynrica*, but the transverse lines are only distinct at the inner margin. Hindwing brown, somewhat diaphanous towards the base. Brazil (Rio de Janeiro).

grisescens. **M. grisescens** Schs. (144 i) resembles *quadrata*, but the colouring is a purer lilac grey, slightly dusted brown only at the costal margin; transverse lines similarly arranged as in the preceding species, the antemedian line double, convergent towards the inner margin, with small reddish-brown costal spots above it; a large quadrangular blackish-brown spot in the narrow median area at the inner margin; a double row of small dark internerval spots at the distal margin. Hindwing white, narrowly brownish on the veins and margin. French Guiana.

castrensis. **M. castrensis** Schs. (144 i) likewise belongs near to the preceding species; forewing brown, reddish at the costal margin, with a lilac tinge at the inner margin, a round black spot before the cell-end, a dark-edged reniform macula at the end itself; the lilac grey distal transverse line is bordered with ochre inside and arises near the apex, extending obliquely to the centre of the inner margin; the distal margin behind it is intensely dusted with lilac. Hindwing white with a golden brown marginal shadow. Brazil.

hirsuta. **M. hirsuta** Schs. differs from the other species in the marking, the violettish-brown forewing showing a broad red-brown shadowy stripe from the centre of the costal margin to the distal margin near vein 3, bordered with blackish-brown below; the transverse lines, excepting the posterior line, are as usual only visible at the inner margin. Hindwing light gregish-brown, veins and margin darker. Expanse of wings: 34 mm. French-Guiana.

albopunctata. **M. albopunctata** Dogn. on the whole shows the same colouring and marking as the other species, but it is easily distinguished by a subterminal row of white dots which are bordered with black only inwards; the lowest of the 3 black dots at the cell-end, which form a triangle, is also marked white; forewing otherwise chestnut-brown in the costal half, lilac brown in the inner-marginal half, the transverse lines bordered with yellowish ochre. Hindwing blackish with light fringe. Expanse of wings: 28 mm. French Guiana.

luteopunctata. **M. luteopunctata** Dogn. (= *aurea* Drc.) (144 i). Forewing very dark chestnut, more reddish in the costal-marginal half, dusted with lilac in some places of the inner margin, with 4 almost straight oblique somewhat lighter transverse lines and 4 small yellow subcostal spots, two of which are before the anterior transverse line, the two others at the upper cell-end; the small black subterminal internerval spots are partly edged with lilac. Hindwing white, brownish on the veins and margin, quite brown in the ♀. Peru and Bolivia.

minna. **M. minna** Schs. (144 i) is the smallest species known and very different. Forewing orange brown in the costal half, on the head and collar, light brownish-grey below it, dusted with lilac in some places, with light reddish-yellow inconspicuous transverse lines and two small round black spots at the cell-end and one in the centre of the cell. Hindwing blackish-brown. Guiana, Colombia.

26. Genus: **Odoxia** Dogn.

Allied to the following genus from which it differs in a frontal hair-tuft, the antennae being shortly ciliated also in the male, the legs densely haired with a pair of long spurs on the hind tibiae. Wings longer and narrower, vein 5 arises from the upper cell-angle, 6 from the centre of the areole; the cell of the hindwing is uncommonly short. Only 1 species:

Type of genus: *O. concocta* Dogn.

concocta. **K. concocta** Dogn. Forewing chestnut-brown, without any markings except a series of very irregularly shaped darker lunules distally accompanied by a darker shadow; it ends at the inner margin near the anal angle and is dusted somewhat white behind it towards the apex. Hindwing monotonously dark chestnut-brown with lighter fringe. Expanse of wings: 32 mm. French Guiana.

27. Genus: **Antiopha** Schs.

♂ antennae very long, dentate, with long ciliary tufts; palpus erect with a very short terminal joint; legs smoothly scaled. Forewing broad and short with a rounded distal margin and long areole, vein 6 arises from it near the upper cell-angle, the subcostal branches, except the uppermost, from its end. Hindwing: veins 3 and 4 arise from the same place, 6 on a short stalk with the subcostal vein.

Type of genus: *A. multilinea* Schs.

A. multilinea Schs. (144 i) has dark lilac brown forewings dusted with grey, with dark red-brown veins *multilinea*, and internerval stripes; a submarginal row of small somewhat lighter, yellowish spots edged with dark brown inside. Hindwing brown with white fringe. Common and widely distributed from Brazil and Colombia.

A. albolinea Schs. is larger than *multilinea*, forewing dark brown mixed with olive and lilac, broadly *albolinea*, lighter and dusted with lilac at the costal and inner margins; veins and internerval stripes darker, as in *multilinea*, distinguished by a white line extending from the centre of the cell along vein 6 to half its length, and thickened behind; traces of a lighter anterior transverse line, antemarginal and marginal rows of small black spots. Hindwing scantily scaled, brownish. Expanse of wings: 47 mm. French Guiana.

A. excelsa Schs. (144 k) is much larger still than *multilinea* and of a more gaudy ground-colour: two *excelsa*, thirds of the costal margin, the basal area and the basal half of the inner margin are brownish-grey, striped darker, the cell and behind it lilac, striped red-brown, the apical third of the costal margin red-brown, the distal half of the inner margin greyish-brown with oblique red-brown streaks; a blackish-brown shadowy stripe along the median vein and its upper branch to the distal margin, before which there are forked red-brown streaks outside, each of which encloses a white dot. Hindwing brownish-grey, lighter towards the base. Costa Rica.

A. collaris Schs. has reddish-brown forewings, being whitish and strewn with red-brown at the inner *collaris*, margin and from there up to vein 4, with an indistinct double darker brown antemedian and postmedian transverse line filled with a lighter colour, the light marginal part with small brown lunules. Hindwing whitish, red-brown at the margin. Expanse of wings: 38 mm. Brazil.

A. modica Schs. Forewing whitish, strewn with brownish ochre, with white veins and very indistinct *modica*, undulate darker transverse lines and two small dark brown spots above the anal angle. Hindwing dull brown. Expanse of wings: 40 mm. Guatemala.

28. Genus: **Marthantia** Schs.

Very closely allied with the preceding genus from which it chiefly differs in the somewhat shorter and not serrated antennae which are ciliated only to the middle, and in dorsal tufts on the 3 first abdominal segments. The areole of the forewing is considerably shorter and narrower than in *Antiopha*, the other neurulation the same; the cell of the forewing beneath is clothed with long hair, the costal-margin of the hindwing is covered with long erect hair. Only 1 species:

Type of genus: *M. stelligera* Schs.

M. stelligera Schs. (144 k). Forewing dark brown in the basal half, reddish-yellow distally, with dark *stelligera*, veins and a brownish apex, with reddish-yellow transverse lines edged with a darker colour, the posterior line much less distinct and followed by a row of white vein-dots, the upper half of which is situate in a darker brown shadow; a double blackish-brown median shadow is fused in the cell, then it separates again, the interior branch being bent back towards the inner margin as far as the base; rows of white dots at the costal margin and before the distal margin. Hindwing brownish-grey. French Guiana.

29. Genus: **Eragisa** Wkr.

This genus comprises mostly large species with thick woolly hair, tuftedly ciliated antennae, thickly scaled rising palpi with a very short terminal joint and especially thickly haired front legs. The neurulation of the broadly rounded wings is the same as that of the two preceding species; base of hindwing beneath very densely scaled.

Type of genus: *E. lanifera* Wkr.

E. lanifera Wkr. (145 a) represents the genus very well also in the colour and marking; the white ground *lanifera*, of the forewing is densely dusted with a mealy grey; the double notched black transverse lines exhibit a course by which the genus is characterized: the anterior line extending obliquely to the centre of the inner margin, the posterior line returning a little distance between the veins 4 and 5; thick black double dots obliquely arranged in the lower half are before the margin between the veins. Hindwing dark brownish-grey with light fringe. Brazil, Colombia.

E. juvenis Schs. has greyish-white forewings, scantily strewn with dark, with fine dark transverse lines, *juvenis*, the anterior line being dentate with an ochreous dot subcostally, the posterior line introangular on vein 2, with bright yellow spots distally; a small white strigiform spot at the cell-end, a dark spot behind it before the postmedian line. Hindwing brown with white fringe. Expanse of wings: 48 mm. Costa Rica.

E. sabulosa Schs. (= *garleppi* Drc.). Forewing greyish-green with double undulate-dentate transverse *sabulosa*, lines, with black and white vein-dots behind the distal line; a large olive green spot is before the white-edged

reniform macula in and below the cell, behind which there is a black spot strewn with red-brown; a larger black and olive green preapical spot at the costal margin, the white undulate line below it. Hindwing brown with a yellowish base and distal margin. Panama.

barnesi. **E. barnesi** Schs. (145 a) has olive green forewings shaded darker, with undulate-dentate fine transverse lines which are accompanied by rusty brown bands, the distal band extending to the anal angle and partly dusted with white and bordered with dark brown, another dentate dark olive line follows behind the latter; darker vein-streaks are in the dark marginal shadow, the darkest between the veins 4 and 5; the brown marginal line is distally bordered with white. Hindwing brown, distal margin narrowly yellow like the fringe, with a darker median line and a dark anal spot which is parted by white. Costa Rica.

nox. **E. nox** Sch. (= *tenebrosa* Rothsch.) (145 a) is one of the largest species and quite different, with bluish-black forewings, feeble brown transverse lines and small costal-marginal spots, the reniform macula surrounded by light brown; velvety black spots partly centred with brown are behind the centre and at the distal margin. Hindwing brown, with yellow hair at the base and at the inner margin, the anal spot parted by light. The ♀ is browner, more contrasting, the reniform macula ochreous, with a postmedian row of white dots. Costa Rica.

ligata. **E. ligata** Schs. was described as a *Heterochroma* (Noctuid), but it belongs to this genus here. Forewing brown, mixed with a lighter colour and reddish-yellow, and shaded darker brown before and behind the cell-end, the veins strewn grey, with brown transverse lines which are bordered with a darker tint; reniform macula large, crescentiform, distally bordered with white, a whitish twice excurved undulate line before the margin; the marginal line is also white, bordered with brown on both sides. Hindwing brown, reddish-yellow at the base, distal margin and fringe. Costa Rica.

bocra. **E. bocra** Schs. (= *indiscata* Dogn.) has dark brown forewings with lighter transverse lines at the costal margin and distal margin, a broad blackish basal band and a dark brown shadow below the median vein; 3 fine black postmedian transverse lines behind which there are 2 round black spots above and below vein 3; a light brown spot traversed by black is at the cell-end, black internodal spots are before the margin. Hindwing blackish-brown with a black anal spot parted by white, and yellow fringe. Expanse of wings: 40 mm. French Guiana.

fassli. **E. fassli** Dogn. has the broadest forewings, reddish-yellow with 4 lighter, partly pale red transverse lines; the large reniform macula is incompletely surrounded with black and in a white ring, a black quadripartite spot is behind it, a double row of white dots on black veins behind the postmedian line. Hindwing blackish with a narrow yellowish distal margin and fringe. Colombia, at altitudes of 2000 to 2200 m.

viridis. **E. viridis** Schs. (145 a) is a very conspicuous light leek-green species with a white cell-end dot and extremely fine black undulate transverse lines. Hindwing brownish black, lighter at the costal margin. Brazil.

30. Genus: **Crinodes** H.-Schäff.

A number of rather large representatives numbering among the largest *Notodontidae*, with ciliated antennae, short, thickly scaled palpi and a small conical tuft on the frons. Mesothorax with a high tuft, abdomen at the end with a tuft of long spatulate hairs. The neuration differs from the preceding species only in veins 3 and 4 of hindwing arising separately.

Type of genus: *C. bellatrix* Stoll.

bellatrix. **C. bellatrix** Stoll (145 b) is the most variegated species and unmistakable for its reddish-yellow forewings and the defined costal margin which is bent down to the end of the discal cell and terminates in a pointed guttiform spot. Guiana and Colombia.

besckei. **C. besckei** Hbn. (= *abseondens* Dr., *dissimilis* Grt.) (145 b, d) is smaller, violettish-brown with a large crescentiform spot which is concave towards the inner margin and situate above the inner margin, dying away distally and bordered inside above by a yellowish line which terminates into another longitudinal line arising from the basal third of the costal margin and extending to the centre of the distal margin; a dark shadowy stripe above this line cuts the acute angle of a subterminal shadowy band before which 2 parallel lines extend. Hindwing yellowish ochreous with a broad brown marginal band. Mexico to Brazil.

ritsemae. **C. ritsemae** Btlr. (145 b) is much larger than the preceding species and combines sooty blackish-brown colour with the scheme of markings of *bellatrix*, but the guttiform spot at the cell-end is transformed into a small dark brown discal streak bordered with light inside; the angled transverse shadows and lines of *besckei* are marked in the distal part, the subterminal line mostly shows yellowish-white vein-dots. Brazil, Colombia.

schausi. **C. schausi** Rothsch. (145 c) differs from *ritsemae* in the more reddish chocolate forewings, a longer stigma — ROTHSCHILD describes it to be not reniform, but numbers of specimens before me frequently also exhibit a

reniform shape —, and in a more longitudinally striped basal costal-marginal area; moreover, the light reddish wedge at the inner margin is much narrower and longer. Mexico to Costa Rica. — **intermedia** *form. n.* (145 d) *intermedia*. may be a form of it, which is much darker blackish-brown with a coppery gloss; the basal costal area is much darker, red-brown, partly shaded with slaty blackish, with the longitudinal stripes of *schausi*; the light wedge at the inner margin is also long, but decidedly higher than in *schausi*. Abdomen much greyer than in the latter form, where it is distinctly ochreous. Hindwing yellowish blackish-grey with ochreous fringe, broadly ochreous at the margin of the ♀ the ground-colour of which is somewhat more reddish and which has also a more purely ochreous abdomen. West Colombia, Rio Dagua (W. HOPP); and Upper Rio Negro (FASSEL leg.); types in the Berlin Museum.

C. mülleri *sp. n.* (145 c) is a new large species distinctly separated from its allies by the ground-colour *mülleri*. being olive grey and not brown, while the marking is more similar to *besckei*. The light area at the base and costal margin is broad, distally contrasting with the dark median area by a light line; discal spot rather inconspicuous, bordered below by the light basal border-line which is continued at the costal margin; behind the discal spot a dark longitudinal shadow extends above vein 4 to the subterminal line; the shadowy lines which are situated here are similarly shaped as in *besckei*; the light inner-marginal spot is prolonged at the inner margin as far as into the basal area and shows a narrow spur above vein 1 towards the margin. Hindwing yellowish olive grey with a darker postmedian line in a flat W-shape. West Mexico (Colima); types in the Coll. DRAUDT.

C. biedermani *Skinner* is probably only a northern form of *schausi*; the marking is almost the same *biedermani*. in both the species; the large light costal-marginal triangle is of a somewhat greyer tint at the base, not so reddish-yellow, its lower border-line is continued almost to the apex and contrasts with the brown part of the wing by a black line; a dark brown discal streak at the cell-end is bordered with light inside; marginal marking quite similar to that of *besckei*. Hindwing brownish-grey with yellowish fringe. Arizona.

C. guatemalena *Drc.* (145 d) has dark brown forewings thickly strewn and watered with a darker colour, *guatemalena*. with a light brown distal margin narrowly bordered with black; an undulate black postmedian transverse line extends upwards again at the inner margin and towards the base; a black spot is at the cell-end. Hindwing similar to those of the preceding species. Guatemala.

C. striolata *Schs.* (145 c). The brown forewing is striated velvet-like darker, especially in the median area *striolata*. and behind the cell, almost black at the inner margin, lighter brown in the basal area and the basal third of the costal margin, bordered below by a light line which forms 2 long pointed dents at the costal margin, which are pronounced by black bordering; a dark transverse streak is at the cell-end, a darker transverse shadow behind it. Distal margin dusted with violettish-grey. Hindwing light brown with a broad subterminal shadow. Brazil. — f. **fuscipennis** *Rothsch.* differs from the nomenclatural form in darker forewings and monotonously *fuscipennis*. greyish-brown hindwings. Venezuela, Costa Rica, and Peru. — f. **insularis** *Rothsch.*, from the West Indies (Trinidad), is suffused with dark cinnamon brownish and thus makes a damaged impression. *insularis*.

C. alector *Drc.* (= *crenulata* *Schs.*) has been introduced in many genera, but it certainly belongs to *alector*. this genus. It is a small, inconspicuously coloured species with brownish-grey, darker striated forewings, with a black inner-marginal streak near the base, a W-shaped shadow at the cross-vein; a light brown spot at the apex and some blackish spots along the distal margin. Hindwing yellowish-brown with a dark subterminal band and small anal spot. Mexico.

C. nebulosa *Schs.* (145 d) is somewhat similar to *alector* and just as small and inconspicuous. Forewing *nebulosa*. light grey strewn with brownish, darker in the subterminal area, a dentate line before the latter, and some small dark spots in the cell; a larger blackish spot is at the upper end of the subterminal area, but it does not reach the costal margin. Hindwing pale grey with a darker median line and marginal band. Abdomen yellowish. Described from Argentina (Tucuman).

31. Genus: **Strophocerus** *Mschlr.*

This genus which is also known as *Poresta* *Schs.* has ciliated antennae in the male like all the preceding genera, smoothly scaled straightly porrect palpi with a long terminal joint, and a large frontal tuft. The broad forewing has a straight costal margin and a pointed, often almost falcate apex. The venation scarcely differs from that of the preceding genera. Most of the species have red-brown forewings provided with a broad grey inner-marginal stripe.

Type of genus: *flocciferus* *Mschlr.*

S. flocciferus *Mschlr.* (= *striolata* *Dogn.*) is the chief representative of this group: forewing brown, *flocciferus*. with lighter transverse striae and a large darker discal macula; the inner-marginal stripe is pinkish-white, its upper border lilac; the brown oblique line which is edged with yellowish inside extends from the inner margin rather straight upwards, bends distally on the uppermost radial branch and terminates below the apex into

the distal margin which exhibits a series of black, distally white internerval dots. Hindwing brown, fringe white, brown at the anal angle. Guiana.

albo-notata. **S. albonotata** Drc. (145 e) resembles *flocciferus* in the red-brown forewings with yellowish-white transverse striae, though it has no discal spot, but a thick white basal dot; the inner-marginal stripe is grey, the marginal dots are absent. Hindwing red-brown with white fringe. Peru and Bolivia.

striata. **S. striata** Drc. The transverse striae of the dark brown forewing are black here instead of whitish, the inner-marginal stripe and the discal spot are absent, only a light brown oblique line from the apex to the centre of the inner margin is present. Described from Eastern Peru.

thermesia. **S. thermesia** Fldr. Like the following species, it has unicoloured red-brown, not transversely striated forewings with a broad blackish-grey inner-marginal stripe which is bordered with white above and bends upwards at the anal angle; discal macula absent, the fine oblique stripe is rather straight. Guiana.

punctulum. **S. punctulum** Schs. (145 e) differs from the very similar *thermesia* in the black cell-end dot, the inner-marginal stripe is white above and has a greenish tint, the black oblique line is shaded with dark violet distally like the distal margin, which shows black, grey-dusted internerval dots and analwards a curved marginal line distally edged with white and grey. Hindwing blackish-brown with a reddish-yellow inner-marginal stripe. Costa Rica.

sericea. **S. sericea** Schs. is also very similar to the preceding species, but the forewing is lilac brown with a silky gloss, the darker brown costal-marginal stripe is broad, narrower towards the apex; the inner-marginal stripe is light lilac, strewn with red-brown, dark grey at the inner margin itself; a large triangular black linear marking at the cell-end approaches the red-brown oblique line which is edged darker outside, reddish-yellow inside; black, white-centred dots at the margin. Hindwing blackish-brown, yellowish towards the base, fringe white. Expanse of wings: 43 mm. French Guiana.

rectilinea. **S. rectilinea** Dogn. (145 e) resembles *sericea*, but it is more red-brown, the discal spot is much smaller, more quadrangular and remote from the brown oblique line which does not proceed from the centre of the inner margin, but only from the distal second third; the inner-marginal stripe is glossy white, red-brown at the inner margin. Hindwing red-brown, lighter towards the base. French Guiana.

orbipunctata. **S. orbipunctata** Dogn. Forewing rusty yellow as far as the oblique stripe behind which it is dusted with lilac, the inner-marginal stripe is violetish-brown, white above, in its continuation at the distal margin near the anal angle there are two white crescents bordered with red-brown inside, dusted with brown outside, 5 fine black internerval dots above them; a circular red-brown macula in the lower cell-end. Hindwing red-brown, lighter yellowish towards the base. Guiana.

cossoides. **S. cossoides** Schs. (145 e). Forewing dark brown, dusted with olive in the median area, with lilac in the marginal area, reddish-yellow at the base and inner margin, and with a long narrow reddish-yellow area at the costal margin behind the centre; posterior transverse line only traceable; two silvery white spots bordered with brownish-black are below and above vein 2, the upper spot being larger; an interrupted black line is above them. Hindwing dark brown, lighter towards the base. From British Guiana.

chliara. **S. chliara** sp. n. (145 e) represents a very different type. Forewing olive grey with an intense silky gloss, with double subbasal, antemedian and postmedian curved transverse lines composed of blackish crescents, reddish-yellow spots strewn with red-brown below the cell before the antemedian line and in the centre of the inner margin, the former spot being small; a somewhat obliquely W-shaped reddish-yellow reniform macula at the cell-end is strewn with red-brown, and a small silvery white spot at the lower end outside and inside; this spot is followed outside by a black oblique shadowy line extending from the centre of the costal margin to the distal margin between veins 2 and 3; a subterminal row of red-brown, inside yellow spots, small red-brown, inside yellow dots behind them. Hindwing light brownish-grey. Head and collar reddish-yellow, thorax and abdomen olive grey, base of abdomen with a red-brown tuft mixed with yellowish-red; middle and hind tibiae light scarlet. The magnificent species is described according to 1 ♂ from West Colombia (Coll. NIEPELT). type in the Berlin Museum.

32. Genus: **Lepasta** Mschlr.

On the whole, it differs very little from the preceding genus; separable by its somewhat narrower wings, vein 6 arising a little deeper near the upper cell-angle; palpi more slender and erect, middle and last joints almost of the same length.

Type of genus: *L. bractea* Fldr.

bractea. **L. bractea** Fldr. (144 k). Forewing light pink mixed with greenish olive and strewn with black, very dark olive-brown along the submedian fold and before the fine double undulate submarginal line, broadest towards the costal margin; a yellowish-white longitudinal stripe along the discal fold is finely bordered with

blackish-brown below and terminates with a point towards the apex before the subterminal darkening; the marginal area is lightest, pink inside, olive brownish outside. Hindwing brownish-grey, darker towards the margin. Mexico to Brazil. — f. *majorina* Dogn. (= *gigantea* Rothsch.) is a much larger race (the ♀ has an expanse of almost 5 cm) from Ecuador and Colombia, in which the black subterminal line is more dentate and 3 white costal-marginal striae are very conspicuous in the distal third.

L. brabilla Dogn. (144 k) is allied with *bractea*; forewing greyish ochre, with a pink subcostal and submedian tinge, 3 yellowish-white longitudinal stripes, the thickest being below vein 5 as far as half its length, the two other thinner ones below the median vein and between its lower branches; black strewing is condensed into internerval stripes as far as the regularly dentate subterminal line; a white lunule is at the lower cell-end, the apex is parted by a whitish patch. Hindwing blackish. French Guiana.

L. omaiensis Schs. is greenish olive on the forewing, dark grey at the inner margin, with traces of pinkish-white median and postmedian transverse lines, connected by a broad pink blotch along vein 5; black internerval streaks behind them, condensed towards the costal margin into a black shadow; distal margin broad grey with a black undulate-dentate subterminal line which is shaded with dark olive inwards. Hindwing greyish-brown, darker distally. British Guiana.

L. viridis Schs. has bright moss-green forewings with a broad dark grey stripe at the base of the costa and 4 white costal-marginal dots behind the centre; a dark grey shadowy stripe begins narrow near the apex at the costal margin, extends curved and much broader to vein 2, where it is connected with the centre of the cell by a dark green and grey spot, with whitish dusting above it; distal margin dark green, spotted grey. Hindwing violettish-brown, lighter towards the base. Expanse of wings: 33 mm. French Guiana.

L. marcella Schs. has reddish-yellow forewings dusted with grey and strewn with brown, a brown shadowy stripe is angled on the median vein and grows more distinct towards the inner margin; a white longitudinal stripe at the cell-end forms a long crescent behind it, a broad brown shadow is behind it, its upper half is dusted with white distally. Hindwing blackish-brown, more thinly scaled at the inner margin. Expanse of wings: 34 mm. Costa Rica.

L. pittieri Schs. is very similar to *marcella*, but smaller, of a brighter colouring and with white fringe on the hindwing. The whitish ground of the forewing is thickly strewn with brownish and olive grey, with a dark spot below the base of the cell, distally bordered by a white line, a costal spot behind it extends down to the median vein; anterior transverse line white, partly edged with yellowish, more thickly towards the inner margin; a large olive grey spot in the lower cell-end is bordered with blackish-brown, a white line above it; behind it follows a broad dark, distally white-edged shadow in the apical half to the apex, an interrupted line at the margin is dotted white at the ends of the veins. Hindwing whitish greyish-brown with white fringe. Expanse of wings: 27 mm. Venezuela.

L. branda Schs. Anterior body white mixed with brown, abdomen wood-coloured brown. Forewing somewhat similar to that of *marcella* and *pittieri*, costal margin brown, base of cell and inner margin as far as vein 2 white strewn with olive brown; a short thick black streak before the centre above vein 1; a purely white line in the distal half of the cell is bent down below vein 5, then bent up to 7 and descends again as far as 6 to the subterminal line, an olive brown shadow above it and below it, reaching the margin at vein 3; the black subterminal line is undulate-dentate; the marginal cellular areas above 5 and 7 are white, strewn with olive. Hindwing brownish-grey. Expanse of wings: 30 mm. Amazons (São Paulo de Olivença).

L. lanassa Drc. (= *parvipuncta* Dogn.) (144 k) is a differently coloured and marked type with somewhat narrower forewings of an olive green ground-colour strewn with violet-brown, the most densely so in a triangular postmedian area which is bordered above along the discal fold by a yellowish stripe which is expanded distally into a small triangular silvery white spot; above it follows a yellowish-ochreous splinter-spot to the margin, traversing the black dentate subterminal line. Hindwing brownish-grey, lighter towards the base. Panama to Brazil.

L. mixta Mschlr. (= *calophasioides* Kaye) (144 k). Forewing red-brown mixed with darker brown, lightest at the base, darkest towards the cell-end, a whitish lunule behind it; a dark brown postmedian transverse band is brightened distally and exhibits 2 or 3 undulate transverse lines subterminally; inner margin brown except base. Hindwing brown. Trinidad, Guiana; West Colombia.

L. maonica Schs. is allied with *mixta*, but much darker. Forewing red-brown with black veins edged with dark violet on each side, violettish-grey at the distal margin, with a velvety black dentate line interrupted by the veins; a dark shadowy stripe before it extends along the inner margin to the base; a short white streak above the distal half of the inner margin; the lower third of the distal margin is dusted with yellowish-green. Hindwing dark brown with yellowish fringe. Expanse of wings: 39 mm. Guiana.

L. lignistriata Schs. (145 f) is a very inconspicuous species with grey forewings strewn with brown, with a darker costal margin and darker internerval streaks; a grey and black small spot is at the base of the costa,

4 white striae at the distal third of the costal margin, a series of black dots before the margin. Hindwing reddish-brown, lighter towards the base. Rio de Janeiro.

conspicua. **L. conspicua** *Btlr.* (145 f) has dark olive brown forewings with a broad reddish-white costal-marginal stripe which is strewn with dark brown upwards and bordered with white below, the marking is similar as in the well-known *grammodes*, but the centre of the wing shows only two broad yellowish-white longitudinal stripes which are bordered with black and almost connected by a small oblique white spot at the cell-end; the lighter reddish-brown marginal area, beginning from vein 4, is alternately traversed by white and black lines. Hindwing brownish-grey. Brazil.

concordens. **L. concordens** *Dyar* is very similar to *conspicua*, but it has longer wings and less oblique markings, quite pink in the subcostal area, the white band below it is broken; the submarginal band is also pink, white colour is only traceable at the margin, it extends along the submedian fold inwards and meets the basal band obliquely, not rectangularly, and is separated from it by a fine line of the ground-colour. Mexico (Chiapas), Costa Rica.

magnistriata. **L. magnistriata** *Dogn.* resembles *concordens*, but the oblique striae of the forewing are still finer and longer; forewing olive brown, subcostally pink with a white streak at the base of the costal margin; 4 brown parallel lines before the margin are separated by pink dusting, the third, counted from the distal margin, is bordered with white inside. Hindwing brownish, base and fringe lighter. Expanse of wings: 40 mm. From the Rio Songo (Bolivia).

grammodes. **L. grammodes** *Fldr.* (145 f) shows the same type of marking as the preceding species, forewing olive brown with a broad reddish-white subcostal stripe strewn with dark towards the costal margin and bordered by a yellowish-white line below, which extends slightly widened to the base of the inner margin and shows a slight indentation behind the cell; a yellowish-white streak at the base of the costal margin; 3 broad yellowish-white wedges in the centre of the wing are bordered with black, the lowest along the submedian fold is striped reddish-brown; an oblique white lunule behind the cell-end; subterminal area reddish violet-brown with a yellowish-white, distally black line. Hindwing greyish-brown. Brazil.

argentilinea. **L. argentilinea** *Drc.* is allied with *grammodes*; forewing dark brown with a broad pink costal-marginal band, bordered below by a silvery line; the submarginal line extends from the anal angle still farther along the fold to the base; the 3 light wedges are silvery stripes, another yellow line is before the margin. Hindwing light brown. South-Eastern Peru.

maltha. **L. maltha** *Schs.* (145 f) is quite dissimilar to the other species, with olive grey forewings, brown at the costal margin, with a white spot at the base of the costal margin, an olive brown cell with a white spot in it and one behind it, distally bordered by a yellowish posterior transverse line; the dark cellular colour forms a dent along vein 2 downwards distally to the postmedian line, where there are two small dark spots; inner margin more greyish-white with a dark triangular spot before the centre and a whitish triangular spot behind it; distal margin dusted with lilac grey, with a dentate black submarginal line. Hindwing red-brown, darker at the margin. Guiana, Colombia.

33. Genus: **Tachuda** *Schs.*

Distinguished by still longer, narrower forewings which are just as broad behind the base as at the distal margin; base of inner margin hairy; veins 3 and 4 arise distinctly separated, 5 close above the upper cell-angle from the short areole. Hindwing as in *Lepasta* and the preceding genera. Antennae tuftedly ciliated, palpi erect with a short terminal joint. The spurs of the hind tibiae are very long, the legs hairy. Half a dozen of species are known, partly difficult to separate.

Type of genus: *T. albosigma* *Drc.*

albosigma. **T. albosigma** *Drc.* (145 f) has violettish-brown forewings strewn with blackish, with 3 green spots in the median area subcostally, below the median vein and at the inner margin, a lilac whitish area in the distal half of the cell, and numerous mostly double undulate black transverse lines behind it; a black streak dotted white above and below is at the cell-end, a thick yellowish-white dot at the apex. Hindwing brownish-grey with white fringe. Mexico to Brazil.

discreta. **T. discreta** *Schs.* (145 g) is similar to *albosigma*, but without the green admixture, of a more greyish-brown ground-colour, with a double cell-end streak which is dotted white above and below; behind the postmedian black vein-dots follows a dark brown line, then 2 dark brown transverse shadows; lilac dusting before the submarginal spots. Sometimes a larger purely light grey area is in the centre of the inner margin. Hindwing dark brown with light fringe. Guiana, Brazil, Trinidad, West Indies.

nefanda. **T. nefanda** *sp. n.* (145 f) is very similar to *albosigma*, but it has still narrower and apically more pointed forewings without the variegated lilac admixture in the median area; all the three green spots of the median area are present, but darker and narrower; a fourth elongate spot of green dusting is at the base of the costal

margin, which is absent in *albosigma*; all the transverse lines are much finer black, mostly interrupted in the centre of the wing, the large black spots in the subterminal area are altogether absent, the white dots below and above the cell-end streak and at the apex are extremely small; a regular row of fine black submarginal dots, irregular in *albosigma* and with larger spots; both species exhibit a small lighter rusty brown spot behind the cell-end. Numbers of both sexes from Mexico (Misantla, Tabasco). Type in the Coll. DRAUDT.

T. lignea Schs. (= *angustipennis* Schs.) (145 g). Forewing grey mixed with moss-green, with a dark *lignea*. brown nebulous stripe from the cell to the apex, often also another one along the inner margin, with double black transverse lines, another one behind the distal transverse line, so that 4 are together there, but the latter often interrupted in its centre; a black streak at the cell-end with a white dot below it; 3 large steel-grey spots before the margin, followed by a row of black marginal dots, a white dot at the apex. Easily separable from all the other species by dingy white hindwings with a brownish-grey marginal band. Expanse of wings: 32 mm. French Guiana.

T. nigella Dogn. Forewing greyish-brown, irregularly strewn and striated darker and scantily strewn *nigella*. white, with a white submedian dot at the base, a red-brown spot bordered with white below the median vein at the origin of vein 2, and with two large black oblong spots, the first at the cell-end, the second subterminal at the same height; black internerval angular streaks edged with white inside are before the margin. Hindwing blackish. Expanse of wings: 45 mm. Guiana.

T. sagittula Dogn. Forewing blackish mixed with red-brown, with an ochreous tinge in the cell and *sagittula*. behind it, blackish submedianly as far as the cell, a black streak in the distal half of the cell, with 4 or 5 red-brown, parallel, interrupted postmedian transverse lines. Hindwing light brownish-grey. Expanse of wings: 37—44 mm. Colombia (Tolima, Quindiu).

T. stellata Dogn. (145 g) with especially long and narrow forewings of a red-brown colour, greenish or *stellata*. bluish white at the base of the costal margin, around the lower cell-angle and in the centre of the inner margin, with black veins thickly dotted white; 3 large white dots at the cell-end, two subcostal ones, and one at the lower cell-end; 3 large round black spots in the subterminal area, followed by a row of fine black internerval dots bordered above inside with white. Hindwing whitish, brownish on the veins and margin. Guiana to Brazil.

34. Genus: **Contrebia** Wkr.

Distinguished from the allied preceding genus by the porrect palpi with a longer terminal joint. Forewing just as long and narrow, but apex pointed, almost falciform. Both the cellular branches of the hindwing are stalked. Only one species:

Type of genus: *C. extrema* Wkr.

C. extrema Wkr. has light reddish-brown forewings, lighter yellowish-white in the costal-marginal area, *extrema*. shaded with dark brown at the inner margin; both the almost straight transverse lines are distinct only near the inner margin, the posterior line extends obliquely to the apex; the median line is striped black and is continued along vein 4 to the margin, but it is interrupted at the cell-end by a large white reniform maenla; no undulate line. Hindwing scantily scaled, brownish-grey, with a black spot parted by white at the anal angle. Brazil.

35. Genus: **Eumaschane** Schs.

♂ antennae pectinated to the tips, the second joint of the palpus is very long and expanded at the end, the last joint short. Forewing with a straight costal margin, a falciformly pointed apex, a slight indentation below the apex and a large lobate projection at the inner angle; areole long; vein 3 of hindwing separated from 4. Only one species:

E. laura Schs. (145 g) is a small pretty lilac grey species with a silky gloss, a white-edged oval around *laura*. the distal half of the cell, with a whitish angled line before it, another one below it as far as the submedian vein and a curved cell-end streak, as well as a similar posterior transverse line which is bent around the cell and extends undulated to the submedian vein; some black striae at the margin. Hindwing reddish-yellow, brown at the margin. French Guiana.

36. Genus: **Hyparpax** Hbn.

Allied to the preceding genus and chiefly distinguished by the very broad wings with a rectangular apex and a convex distal margin. ♂ antennae most strongly pectinated, the slender long palpi porrect. Neuration

scarcely different from that of the preceding genus. A few pretty North-American species mostly coloured pink are known.

Type of genus: *H. aurora* Abb. & Sm.

- aurora.* **H. aurora** Abb. & Sm. (= *rosea* Wkr., *venusta* Wkr.) (145 d) has ochreous forewings dusted with pink in the basal and terminal areas, the yellow median area edged by two darker pink lines. Hindwing white with a pink marginal line. Distributed in the Atlantic States. — Larva somewhat like that of a *Cerura* owing to the green colour with a brown saddle-spot, a raised 4th segment and an upright end of the body, though with but one point; it lives on various species of oak and pupates in a thin case in the earth.
- venus.* **H. venus** Neum. (145 g) is quite pink, only the head is yellowish, the forewing with whitish antemedian and postmedian transverse lines. Hindwing white with a pink marginal line, abdomen yellowish with a pink anal tuft. This typical form seems to be known hitherto only from Colorado and is scarcely variable, whereas
- minor.* the much smaller form — **minor** B. & Benj. is of a much greater variability, the ground-colour being somewhat less pink, the two transverse lines much nearer together. Described from Texas (Kerrville).
- perophoroides.* **H. perophoroides** Stkr. (= *tyria* Sloss.) resembles *aurora*, the forewing is yellowish red-brown, more or less dusted with red, with 2 fine elaret-coloured transverse lines and a third oblique line between them. Hindwing white, suffused with elaret-colour in the distal quarter. The live insects are said to exhibit a bluish-green gloss on the thorax and the base of the forewing, which disappears immediately in the dead insect. Florida and Texas. — f. **aurostriata** Graef shows broad golden yellow longitudinal stripes in the cellular areas of the forewings.
- aonides.* **H. aonides** Stkr. likewise resembles *aurora*, but the forewing is still much more brownish, though with a somewhat olive tint, the pink colour being only traceable on the fringe; transverse lines red-brown, broad and faded, a small paler reniform macula at the cell-end; the median area between the two transverse stripes is not more yellow than the other ground. Hindwing dingy white. Described from Texas.

37. Genus: **Kalkoma** Schs.

Separated from the preceding genus by the shorter pectinated antennae and the longer shape of the wings with a rounded apex and distal margin. The areole of the forewing is long and narrow, vein 3 of forewing arises together with 4 from the same base, in distinction from *Hyparpax*.

Type of genus: *K. alba* Drc.

- alba.* **K. alba** Drc. (145 g) has white forewings densely strewn with black, with an undulate dentate black posterior transverse line and a more intensely notched black submarginal line. Hindwing white, with yellowish hair at the base and inner margin. Panama.
- pylaon.* **K. pylaon** Drc. (146 a). Forewing olive grey, white at the costal margin with small black spots from which darker olive green transverse lines proceed; two black spots parted by white are at the anal angle, a series of black dots before the margin. Hindwing brownish yellow. Honduras.
- cynedryda.* **K. cynedryda** Schs. (146 a) is similar to *pylaon* in the marking, but the ground-colour is light cinnamon-brown, dusted with whitish at the base, the costal spots and the transverse lines proceeding from them are chestnut brown, the anterior ones more broken up into spots; the double postmedian line is very strong inside, very fine outside, chestnut brown internodal spots behind the latter; undulate line dusted with whitish. Hindwing light yellowish reddish-brown. French Guiana.
- zapata.* **K. zapata** Schs. is a small species dissimilar to the others, with grey forewings, white at the base, defined by a double black basal line; the area from here to the double black antemedian line is dusted with pink; the cell-end is lighter grey, a pink shadow parted by dark is at its end; a broad blackish-brown costal-marginal shadow is behind the fine black postmedian line, the black undulate line is irregular, bordered with white inside. Hindwing white with a dark central luna and a transverse line behind it, as well as a broad apical shadow. Mexico (Sinaloa).

38. Genus: **Eudmoe** Hbn.

This is probably the strangest Notodontid genus and may be ranged as *Noctua* in some collections. The typical representative is a rather large, slender insect with long palpi projecting far beyond the tufted vertical hair, with a densely haired middle joint and an almost just as long thin terminal joint; tegulae with long projecting hair. The rather long forewing is very slightly excurved below the apex, the two branches proceeding from the lower cell-angle arise separately, vein 5 comes out a little above the centre

of the cross-vein, 6 arises very near to the base of the long and narrow areole; neuration of hindwing like that of *Kalkoma*.

Type of genus: *E. arne* Cr.

E. arne Cr. (146 a). Forewing blackish-brown, lighter at the margin, more yellowish, with fine yellowish *arne*. subcostal, median and submedian veins, as well as the branches proceeding from the lower cell-angle and two fine acutely angled transverse lines, the anterior one angled near the lower cell-angle, the posterior one on 5. Hindwing black with a white apical spot. Abdomen and hind tibiae scarlet, the former above on the first 4 segments and at the anal end black with a blue reflection. Guiana.

E. aparta sp. n. (146 a) is somewhat like *arne*; forewing greyish-black, somewhat lighter towards the *aparta*. margin, the median vein as well as 3 and 4 greyish-white like the transverse lines, the anterior line only distinct below the cell, the two parts distantly separated, the space between them filled with velvety black, a fine median line is acutely angled at the cell-end, the posterior line parallel to it, double, filled with black and almost reaching the margin on 4, interrupted by the interspace of the veins 3 and 4, which is filled with velvety black; the upper half of the marginal area and the fringe are white; three oblong black subapical spots are in the white submarginal area, the lowest spot being the smallest, a short black marginal line behind them. Hindwing black with a narrow white margin and fringe. Body black, ventrum except the two last rings, hips and tibiae light scarlet. 1 ♂ from West Colombia (Bella Vista), type in the Coll. NIEPELT.

E. carrieta Schs. Head and thorax dark brown, abdomen as well as middle tibiae and hindlegs light red, *carrieta*. only the base and the anal segment blackish-brown. Forewing dark brown, margin broad cinnamon brown; the feeble subbasal line is darker, strewn with grey, a small cinnamon spot behind it below the cell; anterior transverse line double, grey, filled with white towards the inner margin; a cinnamon-brown spot surrounded by white and strewn with white is at the cross-vein; the fine double postmedian line cuts a broad grey oblique shadow from the apex; subterminal white strewing between the dark marginal veins. Hindwing brownish-black. Expanse of wings: 45 mm. Brazil.

39. Genus: **Didugua** Drc.

The ♂ antennae are not pectinated to the tips, the palpi very long, the second joint just as long as the terminal joint, a high hair-tuft on the head. The neuration on the broad forewings and hindwings is not different from that of the preceding genus.

Type of genus: *D. argentilinea* Drc.

D. argentilinea Drc. (146 a). Forewing brown, lighter and more yellowish below the median vein, with *argenti-* darker longitudinal stripes, broadly dusted with lilac grey at the costal and inner margins, with two very *linea*. characteristic yellowish-white, harpoon-shaped spots in the cell and behind it; a brown, pointedly notched subterminal undulate line is bordered with a lighter colour on both sides, the margin is yellowish grey, traversed by two broad lilac grey undulate lines between which there are two very fine blackish-brown ones. Hindwing brownish-grey with light fringe. Mexico.

D. leona Drc. (146 b) is very similar to *argentilinea*, but larger and much darker brown, particularly the *leona*. hindwings blackish brown; the distal appendage of the exterior harpoon-spot is shorter than in *argentilinea*, the almost straight, variably light and dark marginal lines are absent, replaced by a fine black lunulate line. Mexico, Panama.

D. modica Dogn. is a very small species with dark brown forewings, an oblique antemedian line below *modica*. the cell and a white guttiform spot with its apex towards the upper cell-angle. Amazons (Obidos).

40. Genus: **Dasylophia** Pack.

This genus comprises a large number of partly very similar species of a uniform exterior. ♂ antenna pectinated as far as two thirds of its length, last joint of palpus short, a tuft of scale-hairs on the vertex. The forewing has a mostly distinctly dentate distal margin, vein 5 arises from the centre of the cross-vein, 6 either from the upper cell-angle or from the areole close next to it; veins 3 and 4 of the hindwing arise close beside each other from the lower cell-angle, 6 is stalked with the subcostal vein.

Type of genus: *D. anguina* Abb. & Sm.

D. anguina Abb. & Sm. (= cucullitera Herr-Schäff., punctata Wkr., cana Wkr., signata Wkr.) (146 b). *anguina*. Forewing ash-grey, strewn with white basally, scantily strewn with black on the veins, with fine black basal rays and 3 fine subapical longitudinal stripes; a feebly curved double postmedian transverse line contains fine black dots, two thick black dots are in the subterminal area just below the centre, followed by a blackish-brown

punta-gorda. lunular line behind them. Hindwing whitish, brownish at the margin, quite brownish-grey in the ♂. — f. **punta-gorda** *Sloss* is a smaller form with more sharply contrasting black markings on a very light whitish-grey ground. *saturata*. From Florida. — f. **saturata** *Barnes* is a rare western race from Colorado (Denver), with a light reddish-yellow ground-colour, somewhat grey only at the inner margin, and without the black basal ray. Hindwing yellowish-white with slightly smoked veins. The typical form is distributed from Maine and Massachusetts to Florida and Texas. — The larva is straw-coloured before the last moult, then flesh-coloured with a raised black knob on the 8th segment, a fine black dorsal line and 3 fine black lateral lines; with its claspers raised, it sits on different Papilionaceae such as Indigo, Clover, moreover on *Lespedeza capitata*, *Baptisia tinctoria*, and other plants, and makes a web between leaves and earth.

thyatiroides. **D. thyatiroides** *Wkr.* (= *interna* *Pack.*, *tripartita* *Wkr.*) (146 b) is more brownish than the preceding species, with a contrastingly light median area and a darkened base defined by an anterior transverse line which is absent in *anguina*. Hindwing light greyish-brown. Its range seems to be confined to Maine, New Hampshire and New York. The larva is reported to live on *Carya*.

guarana. **D. guarana** *Schs.* (146 b) is allied to *thyatiroides* by the light median area, but the basal area is light, too; the ground-colour is almost yellowish white, strewn with black, without the black basal ray, with a more or less distinct median line which is distinctly double especially below the cell and extends very obliquely towards the base; postmedian line slightly bent, broad, light, parted by dark, forming an inward angle in the submedian area and spotted thickly black behind it, the subanal area behind it almost white; the distal area is otherwise very dark blackish-grey with rather inconspicuous light and dark undulate-linear sagittae and 2 larger black spots above the white anal angular spot; hindwing whitish-grey, smoky at the margin. Mexico to Brazil.

basitincta. **D. basitincta** *Dogn.* (= *nigrescens* *Schs.*) is allied to *guarana*; distinguished by somewhat darker brownish-grey forewings with an entirely blackened basal area which encloses two black basal rays in and below the cell, lighter brownish behind it with a black median line, and a whitish subcellular brightening behind it; the triangular black subterminal shadow is very broad at the costal margin, ending pointed on the lower median branch; otherwise like *guarana*. Expanse of wings: 43–47 mm. Mexico, Costa Rica.

goraxa. **D. goraxa** *Schs.* (146 b) differs from *basitincta* in the basal area not being entirely blackened, only below the base there is a distally rounded black spot which narrows down basad obliquely to the inner-marginal vein; the veins behind the centre are distinctly striated black; the triangular subcostal shadow grows narrower already on the lowest radial branch, widening again a little below it. Hindwing whitish with brownish veins as in the preceding species. Expanse of wings: 38 mm. Mexico.

colimata. **D. colimata** *Dyar* (146 b), from the same affinity of the 3 preceding species, is more greyish-white in the ground-colour, yellowish at the costal margin, with a brownish tint in the cell and in the costal half of the marginal area; with brown internerval streaks; the black basal ray is absent; a fine black dot is in the lower cell-angle; the triangular dark subterminal shadow is feeble, brownish-grey, and terminates on the lowest radial branch, 2 jet-black spots are below it; the posterior transverse line is fine double, feebly angled submedianly, without the black dot of *guarana* behind it. Hindwing light brownish-grey, broadly darkened at the margin. Mexico.

placida. **D. placida** *Schs.* is likewise very similar to *guarana*, but the male has plain antennae, while *guarana* has pectinated ones. Ground-colour of forewing light brown, feebly strewn with lilac grey, grey in the distal half of the inner margin with black-strewn veins and dark basal rays; a darker median shadow extends very obliquely to the inner margin and has here a fine red-brown shadow before it; a larger velvety black spot is in the lower cell-angle; red-brown dusting above the anal angle behind the double postmedian shadow, the black spots are here as in the preceding species. Hindwing whitish, brownish on the veins and margin. Expanse of wings: 40 mm. Costa Rica.

ligea. **D. ligea** *Dogn.* Forewing greyish-brown as far as the postmedian line which has the same shape as in *colimata*, with olive internerval stripes, blackish-brown behind it, mixed with olive, the black veins striped white on both sides, otherwise marked as the preceding species, but without basal rays and black anal spots. Hindwing blackish, lighter towards the base. Expanse of wings: 43 mm. Argentina.

robusta. **D. robusta** *Jones* (146 b). Forewing light brown, dusted darker, the anterior double transverse line more distinct than in the preceding species, otherwise of the same course, with a long black ray below the median vein, a still longer brown longitudinal streak above it, a fine black dot behind it in the lower cell-angle; inner margin darkened brown as far as the postmedian line which has the same shape as in *guarana*, with the same black anal spots behind it. Hindwing brownish ochreous, darker at the margin. Brazil.

lupia. **D. lupia** *Drc.* (146 c) is smaller and lighter than the preceding species with the same, but very fine markings as *guarana*, a quadrangular brownish spot in the distal cell-end, with a black basal ray or without it, and black filling may be below it before the anterior transverse line, as in *goraxa*; the small subterminal black

sagittal spots are connected by blackish dusting and form a continuous line with the distal black shading of the postmedian line not reaching, however, the inner margin. Hindwing whitish with fine brown veins and marginal line. Mexico.

D. mocosa *Dogn.* (146 c). Forewing dark yellowish-brown with darker brown veins, traversed by a brown longitudinal shadow from the base of the inner margin to the apex; no other marking than a submarginal row of small brown internerval wedges. Hindwing light brownish-yellow. Expanse of wings: 52 mm. Ecuador.

D. riparia *Drc.* has light grey forewings, longitudinally striped brown as far as the cell-end, behind which it is blackish-brown as far as the apex and distal margin, with a fine notched light grey submarginal line. Hindwing white, veins and inner margin light brown. Peru.

D. grenadensis *Schs.* Forewing reddish yellowish-brown, the veins strewn with black in the distal half, with long dark internerval streaks in the upper half of the marginal area; a dark longitudinal stripe in the cell and a spot behind it, followed by a red-brown transverse shadow not reaching the inner margin; dark marginal dots are most distinct at the apex. Hindwing smoky grey, whitish towards the base, with black veins. Expanse of wings: 44 mm. Grenada (West Indies).

D. inca *Schs.* has dark brown forewings brightened in the centre of the costal margin and at the anal angle, crossed by indistinct transverse lines in the median area; small velvety brown, inwardly reddish-yellow wedges are before the distal margin. Hindwing whitish, broadly smoked on the veins and margin, with traces of a transverse row of vein-dots. Peru.

D. obscura *Dogn.* is allied to *inca*, forewing monotonously brown, strewn with yellowish, two black dots above each other in the cell-end, and the usual light postmedian line behind them, followed by two black subanal spots in lighter yellowish surroundings, a series of black internerval wedges above them, bordered with yellowish in the upper half. Hindwing white, smoky at the margin. Expanse of wings: 37 mm. Argentina.

D. jaliscana *Schs.* (146 c) has somewhat shorter and broader wings, greyish-white strewn with blackish, with fine black veins and double transverse lines of the same characteristic course as in the preceding species, the anterior line especially distinct and extending almost vertically from the costal margin to the submedian fold, where it makes a very sharp curve towards the base, the costal margin before it and behind the postmedian line more intensely darkened in a triangular shape; only a very thick black spot is between the median veins. A black streak on the cross-vein. Hindwing yellowish-white, broadly darkened at the margin. The ♂ is beautifully tinged with chestnut-brown before and behind the median area. Mexico.

D. abbreviata *Schs.* has somewhat shorter and broader forewings than *jaliscana*. Forewing reddish yellowish-brown, densely shaded with brown and olive green, especially at the inner margin, with two distinct transverse lines filled with white, and a black cellular spot between them; the usual two black subanal spots. Hindwing yellowish-white, the ♂ brown with a lighter median band. Expanse of wings: 32—40 mm. Brazil.

D. seriata *Drc.* (= *melanopa Barnes*, *indecoris Schs.*) (146 c) has greyish-brown forewings with black veins and double brown internerval stripes, rather indistinct lighter transverse lines which are nearer together, a black basal ray and a very thick black spot between the lower median veins, the one above it being very small; high red-brown submarginal angular streaks are filled with grey. The larger ♀ shows a somewhat steel-grey reflection at the inner margin and it lacks the black basal ray, but it has a large oval reddish-yellow basal area instead of it. Hindwing blackish-brown. Mexico to Panama.

D. russula *Dogn.* Forewing reddish yellowish-white which colour is brighter in the anterior half with numerous blackish-brown longitudinal streaks and similar lighter transverse lines as in *seriata*; a white subanal spot is parted by black and above it there is a series of dark internerval streaks which are thickened towards the apex and distally followed by white streaks. Hindwing diaphanous whitish. Expanse of wings: 45 mm. Guiana.

D. blaizea *Schs.* is separated from the two following species by the white hindwings. Head and collar wood-brown, thorax almost white, abdomen light brown, the two terminal segments more whitish. Forewing light reddish brown, strewn with brown in the costal-marginal third, a row of black dots below the costal margin in the centre; median line brown, double as far as the lower cell-angle, a reddish-brown shadow before it at the costal margin, the said line bends below the cell inwards to a black spot above the submedian fold, which spot is at the end of a fine black line; inner margin, except at the base, strewn with black; the postmedian line extends to the black spot, then to the centre of the inner margin, a fine double line is behind it, a dark spot below 2; a light brown shadow behind it between the costal margin and 5, with black veins and white, black-edged internerval streaks; a blackish-brown marginal spot between 2 and 4. Hindwing white with light brown marginal veins. Expanse of wings: 58 mm. Guatemala.

D. xylinata *Wkr.* (= *pythia Drc.*) (146 c, d) is one of the most common species; forewing reddish yellowish-brown, dark brown in the basal third of the costal margin and a large subapical triangular spot, broadly blackish-brown at the inner margin; the anterior transverse line is double and very oblique, only marked

below the cell, the posterior line broad, lighter, parted by a red-brown line, an oblique dark brown line behind it in the lower half, followed by a black area edged with white inside, between the lower median veins, the margin behind it blackish-brown, with acute dark triangles above it. Hindwing brownish-grey with light fringe. Mexico to Colombia and Venezuela.

- maxlla.* **D. maxlla** Schs. (146 d) is very similar to *xylinata* in every respect, but the ground-colour is a much lighter clay-colour, the blackish-brown inner-marginal darkening is almost entirely absent, the hindwings are much lighter, too. Mesothorax, being deep blackish-grey in *xylinata*, is just as light loamy yellow as the rest of the thorax. Mexico.
- terrena.* **D. terrena** Schs. (= *dares* Drc.) (146 d) is still more similar to *xylinata*, distinguished by its coarser blackish-brown strewing which effects a darker total colouring and, especially in the ♂, almost extinguishes the ochreous areas, the veins in the distal area are more intensely dotted black and white, the other markings the same. Hindwing darker blackish-brown. Mexico.
- rufi-tincta.* **D. rufitincta** Dyar is likewise closely allied to *xylinata*, with brighter red-brown forewings, somewhat lighter only towards the base, broadly shaded with blackish at the apex, with black-striped veins and double blackish-brown internerval stripes bordered with ochre, discernible by dingy white hindwings which are only smoky at the margin, and the uncommonly long and narrow shape of the forewings. The ♀ is more yellowish, less red, and an unmarked lighter oval basal spot similarly shaped as in *seriata*, shaded darker distally. The hair-tufts at the base of the antennae are much shorter here than in the other species. Expanse of wings: 40—50 mm. Mexico (Cordoba, Orizaba).
- pocila.* **D. pocila** Fldr. (= *fulgens* Drc.) (146 d) is a much larger and more variegated species; forewing reddish-yellow, red-brown at the costal margin, inner margin and anal angle before which there is an oblong spot of greyish-white or greyish-bluish dusting; a red-brown oblique band from the base of the inner margin to the apex; hindwing light greyish-brown, darkened at the margin. Colombia to Brazil.
- dognini.* **D. dognini** nom. nov. (= *saturata* Dogn. nec Barnes) is very closely allied to *pocila*, but of a grey, not reddish-yellow, ground colour and with more intensely developed markings; the brownish-grey colour is intermixed with rosy-reddish, olive and white scales, an oblique white line begins behind the centre of the submedian fold and reaches the distal margin between the lower median veins, and extends from the fold vertically to the inner margin; bluish-white dusting in double blotches is above the anal angle as in *pocila*. The whitish hindwing is crossed by a dark postmedian line, a broad blackish band is at the margin. Expanse of wings: 43—45 mm. Colombia (Socorro, Cali).
- lucia.* **D. lucia** Schs. is a smaller species with reddish-yellow forewings, shaded darker at the costal and inner margins as well as at the veins in the distal area; a submarginal row of blackish wedges with small brownish spots before them, the posterior transverse line is hardly traceable, with small brown anal-angular spots behind it. Hindwing white with a brown marginal shadow. The ♀ is greyer with a large whitish oval spot near the base below the median vein, with more distinct markings. Expanse of wings: 34—47 mm. Sa. Lucia.
- angustipennis.* **D. angustipennis** Schs. is distinguished by remarkably long and narrow wings, similar as in *rufitincta*, forewing brown, lighter reddish-yellow at the base of the costa and at the inner margin, with a very oblique reddish-brown costal-marginal shadow through the centre of the cell, extending from the median vein inwards and finely dentate to the inner margin, behind it the usual double line extending very obliquely towards the inner margin; the lower half of the subterminal area is dusted grey as far as the anal angle, the veins above it are longitudinally striped dark, and with light internerval lines; a white and black spot is behind the traceable postmedian line between the lower median veins. Hindwing white, brownish-grey at the veins, inner margin and apex. Expanse of wings: 46 mm. Costa Rica.
- limbata.* **D. limbata** Dogn. is somewhat similar to *angustipennis*, but the forewings are not so long and narrow; the colour is brown, likewise lighter reddish-yellow at the base of the costa and at the inner margin, the marginal area behind the postmedian line intensely darkened blackish; the reddish-brown oblique shadow is scarcely traceable, the postmedian line behind it double but not so oblique as in *angustipennis*; blackish internerval stripes in the dark marginal area, the veins somewhat lighter. Hindwing whitish, brownish at the margin and veins. Venezuela.
- franzina.* **D. franzina** Schs. has light brown forewings, dusted with violettish-grey at the costal margin and in a shadowy stripe above the submedian vein from the base to the anal angle, a dark brown shadow below the anal angle at the base, an interrupted brown longitudinal stripe in the cell bends downwards as an oblique shadow to the broad whitish posterior transverse line which is bordered by small brown spots on both sides. Hindwing brown. Expanse of wings: 45 mm. Brazil (São Paulo).
- eminens.* **D. eminens** Schs. is a different species with greyish-white forewings, a dark brown costa and a small brown spot before the centre of the costal margin, a brown irregularly excurved median line behind it, which does not quite reach to the inner margin; a black basal ray below the brown median vein, a brown longitudinal streak above it is interrupted by the cross-vein and extends to the margin; an indistinct dark oblique shadow to

the apex begins below the cell-end; the veins of the lower half of the margin are white strewn with black; a fine black oblique line above the anal angle, a black spot behind that line. Hindwing white with brown veins and marginal band. Expanse of wings: 38 mm. Mexico (Sinaloa).

D. abnormis Schs. Forewing brown with a red-brown shadowy stripe extending from the base to the costal margin and from there to the lower cell-end, the area below it being strewn with dark red as far as a curved median line; a round black spot in the lower cell-end, a dot before that spot; a lilac shadow, indistinctly bordered with black above, extends from the cell-end to the anal-angular region; a dentate black postmedian line is only traceable in the lower half of the wing, with small brown marginal spots behind it. Hindwing dark brown with a red-brown anal spot which is parted by white. Expanse of wings: 32 mm. British Guiana.

D. improvisa Dogn. resembles *abnormis* by the brown forewing exhibiting a similar red-brown shadowy stripe which extends curved from the costal margin and traverses the cell, bending upwards at the cross-vein, enclosing a thick white dot before the centre of the cell; the shadowy stripe is continued towards the margin, where it widens towards the apex. Hindwing brown with a blackened margin and white fringe. Expanse of wings: 30 mm. Amazons (Para).

D. osmophora sp. n. (146 e) differs from the other species of the genus in an area of large broad flat reddish-brown scent-scales situate in the median band below and above the submedian fold; forewing light olive brownish with fine darker olive brown notched transverse lines which are bordered with a lighter colour on the averted sides and are very near together on the inner-marginal vein, extending closely together and sharply bent inwards almost to the base of the inner margin; a black dot in the lower cell-angle, another brown dentate line behind it vanishes in an olive brown area which forms the upper border of the scent-scale spot. Subterminal area light in the upper half, narrowly olive brown below the centre, reddish-brown anally with a thick black spot between the median veins, a small one below it and a streak in a brown area above it. Hindwing yellowish-grey, costal margin and distal margin darkened brownish olive, with an indistinct median shadow and light fringe. Described according to a ♂ from an unknown habitat, type in the Senckenberg Museum.

41. Genus: **Farigia** Schs.

A very characteristic genus of strong, medium-sized animals with rather broad rounded forewings which are uncommonly coarsely scaled especially in white and light green. The ♂ antennae are pectinated in the two basal thirds, the palpi are rather short, densely haired, the vertex tuftless. The neurulation is almost the same as in *Dasylophia*, but only two subcostal branches arise from the end of the very long and narrow areole, the second from above arises before the end of the areole. The costal vein of the hindwing branches off close at the cell-end.

Type of genus: *F. sagana* Drc.

F. sagana Drc. (146 e). Forewing whitish-grey from the base to the centre of the costal margin, the other part light yellowish red-brown, strewn with light bluish-green at the inner margin and in a large spot behind the cell; the markings in most of these similar and rather variable species are very inconspicuous in the irregularly strewn ground and consist of fine black, strongly interrupted, double transverse lines, a whitish discal streak and the usually most distinctly marked fine black lunulate line at the margin. Hindwing reddish-brown. Mexico to Brazil.

F. foliata Schs. (146 e) has extensively green forewings with a white, brown-strewn basal third of the costal margin as far as below the cell, bordered by a double antemedian line and a dentate basal line which defines the small green basal area; markings as in *sagana* with small darker shadowy spots in the subterminal area at the costal margin, below the centre and at the inner margin. Hindwing light brown. Costa Rica to Bolivia.

F. tulana Schs. is likewise similar to the preceding species, but the base is brown, followed by a large white costal-marginal spot as far as a little below the cell, bordered by a curved brown line which is darkest below the cell; only the inner margin is green, strewn with brown, the colour above it is greyish-brown with a dark spot at and behind the cell-end, which is strewn with green; the dark brown postmedian line is almost straight, darkest at the inner margin. Hindwing light brown, darker at the margin. The ♀ has a whitish-grey distal margin. Expanse of wings: 32—44 mm. Costa Rica.

F. nana Drc. is allied with *tulana*, smaller, with more light brown forewings, extensively strewn with green and grey, grey at the base of the costal margin, with a more prominent greenish-brown undulated band in the subterminal area. Hindwing light brown, yellowish towards the base. South-Eastern Peru.

F. medan Drc. (146 e) is still smaller, forewing brown, densely strewn with green in the median area, broadly grey in the basal area, the markings of the preceding species very indistinctly indicated. Hindwing darker brown. Colombia.

F. fragilis Schs. Body moss-green, mixed with lilac grey; forewing moss-green at the costal margin and below the cell, lilac in the cell and at the inner margin, broadly white at the distal margin; the dark olive green posterior transverse line is curved around the cell-end, an interrupted green shadow is behind it before

the margin. Hindwing whitish, strewn with lilac at the distal margin, with green hair at the inner margin. Expanse of wings: 27 mm. French Guiana.

- montana*. **F. montana** Drc. (146 e). Forewing whitish-grey, strewn with black and green, bright green in the basal area and the basal half of the inner margin, and in a more or less interrupted submarginal band; markings very indistinct except a somewhat raised white discal streak and a black submarginal lunulate line. Hindwing red-brown. Mexico to Costa Rica.
- vecina*. **F. vecina** Schs. (= *moresca* Schs.) (146 f) is of a more greyish-brown ground-colour, strewn with green, the most regularly and densely so along the two double black transverse lines, the posterior one of which is much stronger; the median area remains the purest brown; a large dark brown spot is usually behind the postmedian line at the costal margin. Hindwing dark brown. Mexico, Costa Rica.
- albicans*. **F. albicans** Schs. (146 f) has white forewings scantily strewn with brown, green at the base below the cell, narrowly green at the inner margin and behind the postmedian line; a large brown subterminal spot at the costal margin, below vein 4 a smaller spot intensely strewn with green, followed farther towards the margin by a larger brown spot. Hindwing brown with white fringe. The ♂ is greyer. Costa Rica to Bolivia.
- mina*. **F. mina** Drc. (146 f). Forewing light greyish-green, finely strewn with black, with a broad white subbasal band and numerous fine black transverse lines behind it, the lunulate line before the margin being most distinct. Hindwing light reddish brown. Colombia.
- peruana*. **F. peruana** Dogn. (146 f) is suffused with pink on the whitish forewings, purely white or light green at the base inclusive of the cell, also at the costal and inner margins; 4 fine brown parallel lines are behind the cross-vein, a blackish, white-dusted subterminal spot is above the upper median vein and a brown marginal line behind the white undulate line. Hindwing yellowish with brown fringe. Peru.
- liboria*. **F. liboria** Schs. (146 f). Body light brown, intermixed with white, ventrum reddish-yellow. Forewing red-brown, strewn with white and light green; a broad green antemedian band is bordered by irregular brown lines; a small black and white spot at the cross-vein; the double brown postmedian line is filled with green, a quadrangular brown spot is behind it at the costal margin; the irregular subterminal line is brown, the distal margin and inner margin strewn with green, the latter more densely so. Expanse of wings: ♂ 38, ♀ 43 mm. Amazons, French Guiana. The contrast between the light median area and the green markings is very remarkable.
- luicana*. **F. luicana** Schs. (146 f). Head and thorax light brown, intermixed with white, abdomen cinnamon brown above. The basal third of the costal margin on the forewing and the cell are white, scantily strewn with light brown, bluish greyish-green below the cell, like the anterior transverse line which is bordered with brown; the area behind it is light brown and white with greyish-green scales at the cross-vein and inner margin, the former marked with 2 dark lines; the somewhat spotted posterior transverse line is blackish-brown, excurved, a sulphur-coloured spot before it at the costal margin, traces of a lighter double line behind it; margin strewn with greyish-green, scarcely strewn between 4 and 6; subterminal line irregularly blackish-brown. Hindwing brown, ends of fringe white. Panama.
- theliana*. **F. theliana** Schs. (146 f). Head and thorax white, intermixed with brown, abdomen reddish-yellow with 3 small brown basal tufts. Forewing white, densely strewn with fawn, especially in the marginal third; from the chestnut-brown basal line a black line bordered with brown extends along the submedian fold to behind the postmedian line which is fine light brown and double, followed by dark spots between 3 and the inner margin; median line light brown, straight as far as 1, then double to the inner margin, behind which there is a narrow red-brown shadow; a black dot at the cross-vein; the irregular subterminal line is light brown, forming oblique streaks between 3 and 4. Hindwing brown with white ends of the fringe. Colombia, Bolivia (Songo).
- alicia*. **F. alicia** Schs. (146 g). Head and thorax cinnamon brown, intermixed with white, abdomen red-brown, scaled white. Forewing green at the base and inner margin, otherwise white, strewn with chestnut brown; transverse lines double, the anterior one dentate as far as the centre of the inner margin, a fine black line on the submedian fold; a small white and black spot at the cross-vein; oblique whitish brightenings behind the postmedian line between 6 and 2. Subterminal line fine, black, forming oblique white-edged streaks below 4. Hindwing light brown, darker at the margin, with white fringe. Bolivia (Songo), Colombia.
- gamarra*. **F. gamarra** Dogn. (= *baladan* Drc.) (146 g) has whitish-grey forewings partly shaded with green, with a violettish-brown median area which is traversed by black transverse lines filled with green, the anterior line double, the posterior line treble; the usual fine black lunulate line before the margin. Hindwing greyish-brown. Venezuela to Peru.
- curita*. **F. curita** Jones (146 g) is coloured like *gamarra*, but also the median area remains white and the transverse lines are quite indistinct; the inner-marginal area is more densely strewn with green, defined above by a black longitudinal stripe on the submedian fold, the space between the latter and vein 2 is more densely strewn with bluish and black; of the double posterior transverse line two lunae near the inner margin are thickest and followed by dark green colour; discal luna black, distally bordered by erect white scales. Hindwing brown, with yellowish hair at the inner margin. Brazil.

F. pallida Schs. is very different and was described as a *Lophodonta*. Forewing greyish-white, shaded with *pallida*. brown at the base, with dark brown double dentate transverse lines, 2 yellow spots distally bordered with brown behind the exterior line between the median branches and above them; a brown shadow in the cell is followed by a dentate line; the subterminal costal-marginal area is dark grey. Hindwing brown, mixed with white at the costal margin, with white fringe. Venezuela (Aroa).

F. catharina Dogn. (146 g) is somewhat similar to *pallida*, but it has longer and narrower forewings and *catharina*. a very long abdomen and is distinguished by an entirely white head and thorax and white hindwings which are brown only at the inner margin, with a small brown spot in the distal quarter of the costal margin. Forewing tinged with pink, scantily strewn with greenish at the base and inner margin, the whole surface rather monotonous, the transverse lines very fine and inconspicuous, a large, prominently white costal spot behind the exterior line. Brazil.

F. musara Schs. (146 g). The grey forewing is shaded with brown at the inner and distal margins, with *musara*. a pink tinge in the disk, double black transverse lines filled with greenish-yellow, the posterior line more prominent, forming a regular bow and broadly shaded with green distally except the area between the veins 4 and 6. Hindwing brown. Brazil (Castro, Parana).

F. benepicta Schs. Thorax brownish, yellow behind, with white shoulders; forewing brownish pink, *benepicta*. strewn with white, most densely so in the median area, with double red-brown transverse lines filled with yellowish-green, bordered in some places with bluish-green and yellow; a red-brown subapical triangular spot at the costal margin is bordered with white. Hindwing brown, fringe white at the ends of the veins. Expanse of wings: 40 mm. French Guiana.

F. larissa Drc. has dark brown forewings, the distal thirds being white; a large grey spot bordered with *larissa*. white at the cell-end and 2 subterminal red-brown spots between the veins 2 and 3 and above them; the usual black lunulate line is before the margin, the other transverse lines are rather indistinct and very fine. Hindwing brown with darker veins. Colombia.

F. xenopithia Drc. is a smaller species with blackish-brown forewings which are densely strewn with *xenopithia*. green; 4 green, black-edged spots are conspicuous at the costal margin, smaller black spots are at the inner margin, and 3 oblong brown spots at the apex. Hindwing red-brown. Trinidad.

F. hydriana Schs. (146 g) has greyish-brown forewings which are darkest at the inner margin, strewn *hydriana*. with light green at the base of the costal margin, with a brown cross-vein spot and a broad dark brown shadow below the cell as far as the undulate line. Hindwing brown. Mexico to Venezuela.

F. conspersata Dogn. (146 g) is allied to *hydriana*, the white forewings are densely strewn with black, *conspersata*. with a thick black cell-end dot, the double black transverse lines only distinct at the costal margin, the rest only indicated by denser strewing; 3 purely white spots in the marginal area. Hindwing quite light reddish-brown. Bolivia (Songo).

F. sennen Schs. (146 h) is somewhat like *magniplaga*. Body brown, intermixed with white. Forewing *sennen*. light brown at the base, strewn with green, reddish-yellow at the costal and inner margins, antemedian area and inner margin densely strewn with light green, bordered above by a curved black line between the transverse lines, above which there is a short similar line along 2; transverse lines brown, the interior line indistinct, the exterior line inwardly interrupted on 4, whitish brightening before it at the inner margin; a spot of white raised scales at the cross-vein, bordered inside with black; marginal area brownish cinnamon with white diffuse spots and a fine brown subterminal line. Hindwing brown, fringe white at the ends. Expanse of wings: 37 mm. French Guiana, Amazons.

F. magniplaga Schs. (146 h) is closely allied to the preceding species from which it is separable by dense *magniplaga*. black shading in the median area, which extends from the distal half of the inner margin into the cell to the subcostal vein; the distal portion of the posterior double transverse line is deep velvety black, distally shaded with dark green. Hindwing dark brown. Mexico to Guiana.

F. basiviridis Dogn. (= *malomen* Dyar) (146 h). Basal third of forewing green with white-strewn veins *basiviridis*. and a thick black, green-strewn basal spot below the cell, the brown median area with a black, distally white-edged discal spot and bordered by one white and two green postmedian lines; the brown marginal third is strewn with white and brown. Hindwing brown. French Guiana.

42. Genus: **Pseudodryas** Mschlr.

Also the ♀♀ antennae are pectinated in the basal two thirds, the erect palpi hairy with a short terminal joint. Forewing narrow with a rounded apex and almost the same neuration as in *Dasylophia*, but vein 5 arises a little above the centre of the cross-vein. The costal vein of the hindwing branches off in the basal third of the upper cell-margin. Only 3 species are known, since several species placed to this genus are to be reckoned to other genera.

Type of genus: *P. olivacea* Mschlr.

- olivacea*. **P. olivacea** *Mschlr.* has olive yellow forewings strewn with brown, shaded somewhat darker at the base and in the marginal area behind the postmedian line; both the transverse lines are indistinctly double, bordered somewhat lighter and dentate, the posterior one followed by 3 dark internerval spots; before the apex at the costal margin there is a dark brown triangular spot below which a light oblique line parts the apex; a few small olive greenish spots in the cell, a light lunar streak at the cell-end. Hindwing brownish-grey. Surinam.
- stragula*. **P. stragula** *Mschlr.* (146 h) is somewhat similar to *olivacea*, the forewing is yellowish olive grey, somewhat more yellow in the median area, edged by two indistinct dentate darker single transverse lines; a large guttiform olive brown preapical spot; the apex itself is not parted by light as in *olivacea*; small dark internerval spots before the margin, double dots at the base of the fringe between the veins. Hindwing brownish-grey. The abdomen exhibits a pear-shaped dark velvety brown spot on the last segments. The species was described from Surinam, but it occurs also in Colombia and Bolivia.
- albiluna*. **P. albiluna** *sp. n.* (146 h) agrees well with the diagnose of the genus, but it looks very different. The whitish ground of the forewing is densely strewn with brownish, more densely in the basal third of the inner margin, with finely black-striped veins; a broad black stripe extends from the basal fifth of the costal margin along the lower half of the cell, then behind it between the veins 4 and 5 almost to the margin, from where it bends round as a notched submarginal line into the costal margin before the apex, a long black wedge is detached from it between 5 and 6 towards the upper cell-end; the black longitudinal stripe is interrupted at the lower cell-end by a thick chalky white crescent; somewhat more whitish colour distally notched occurs subterminally in the lower half of the margin. Hindwing short and round, semi-diaphanous white, veins and marginal line narrowly brown, costal and inner margins brownish. Described according to a ♂ from Joinville (Brazil); type in the Senckenberg Museum.

43. Genus: **Hamidonta** *Dogn.*

The ciliated antenna shows a knotted thickening right behind the base with a hook-shaped appendage; the second very hairy joint of the palpus is upcurved on the vertex, the terminal joint is slender and bent backwards like a hook; the legs are uncommonly hairy. Forewing: vein 5 from the centre of the cross-vein, 6 arises from the arcole, 7 a little below its apex, the two next veins stalked from its centre, and 10 shortly before. All the cellular veins of the hindwing are not stalked. Only 1 species:

- unca*. **H. unca** *Dogn.* (= *muscosa* *Rothsch.*) (146 h) is somewhat like *Drugera morona*; forewing blackish strewn with greenish, with double transverse lines partly bordered or filled with white, a faded black median line between them, the posterior line broken up into small internerval lunae. Hindwing blackish with lighter fringe. Guiana.

44. Genus: **Eustema** *Schs.*

Here four fifths of the antennae are pectinated, the short palpi straightly porrect, the legs moderately hairy. The forewing shows the same neurulation as *Pseudodryas* except that vein 6 arises directly from the upper cell-angle, while the costal vein of the hindwing branches off close at the upper cell-angle. Only a small number of rather similar species.

Type of genus: *E. dara* *Drc.*

- dara*. **E. dara** *Drc.* (146 i) has plain mouse-coloured, scantily scaled forewings with a slight silky gloss, without any marking; anterior part of the body yellowish-brown, abdomen darker brown with yellowish bands. Described from Mexico.
- sericea*. **E. sericea** *Schs.* Body red-brown, with yellow transverse bands on the abdomen. Forewing silky grey, with somewhat darker veins, a feeble darker grey postmedian shadow which is slightly bent below the costal margin. Hindwing with brownish hair at the inner margin. Expanse of wings: 57 mm. Costa Rica.
- opaca*. **E. opaca** *Schs.* (146 i) is very similar to *sericea*, but darker purple brown, beside the abdominal segments also the collar is covered with yellowish ochreous hair. The forewing shows a strongly curved postmedian transverse line which is shaded with darker outside like a spot behind the cell, and bordered with lighter inwards; it is interrupted inwards on vein 4 and extends submedianly very obliquely to the inner margin. Brazil.
- rapana*. **E. rapana** *Jones.* The light brown forewing is greyer at the costal margin and in the anal half, otherwise strewn with dark brown; a darker undulated shadow extends through the centre, with an undulated transverse line behind it, which surrounds the cell, and a brown subterminal line; a white band proceeding from the base of the inner margin extends to the upper edge of the cell, from there to the upper cell-angle where it bends downwards on the cross-vein, forming a small discal luna; behind this band lies a triangular darker area extending to the anal angle; a white spot is shortly before the centre of the inner margin. Expanse of wings: 58 mm. Brazil (Parana).

E. roseilinea Schs. is all white, the inner margin and distal margin of the forewing with a pink hue, and *roseilinea*. a pink longitudinal line along the lower edge of the cell to the margin. Expanse of wings: 37 mm. Bolivia.

45. Genus: **Eustemides** Dyar.

Separated from the externally very similar preceding genus by a stronger vein 5 of the hindwing, the absence of the areole on the forewing and the 3 lowest subcostal branches being jointly stalked. Only 1 species:

Type of genus: *E. carama* Drc.

E. carama Drc. (146 i) is altogether very similar to *E. dara*. Body black, thorax and end of abdomen *carama*. set with long yellowish hairs. Wings light greyish-brown with darker veins and fringe. Peru.

46. Genus: **Tecmessa** Burm.

The ♂ antenna is shortly pectinated at the base, the ♀ antenna serrate, the hairy palpi are short. The rather broad forewing with a straight costal margin and inner margin and a rounded distal margin exhibits the same neurulation as *Dasylophia*, the areole is long and narrow.

Type of genus: *T. annulipes* Berg.

T. annulipes Berg (146 i) (= *phyllis* Drc., *cernata* Dogn.) has a grey body, white head and black collar, *annulipes*. the black legs show white rings. Forewing greyish-white with numerous black dentate transverse lines and speckled fringe. Hindwing purely white. South Brazil (Rio Grande do Sul).

T. elegans Schs. (147 a) is white, with a large black spot on the metathorax. Forewing dusted grey with *elegans*. irregularly dentate double black transverse lines, and a black spot behind the distal line at the anal angle. The white hindwing shows a smoky grey marginal band and a black anal-angular spot. Brazil (Castro Parana).

47. Genus: **Psorocampa** Schs.

Almost exactly like *Tecmessa*, but two thirds of the ♂ antenna are pectinated, serrate at the end, and veins 3 and 4 of the hindwing arise from the same place. Only 1 species:

P. denticulata Schs. (147 a) has greyish-white forewings with two finely dentate transverse lines which *denticulata*. are bordered with reddish-yellow outside. The colour of the hindwings varies from a pure white to slaty grey. Brazil (Castro, Parana).

48. Genus: **Phyllopalpia** gen. nov.

Distinguished from *Psorocampa* by vein 6 of the forewing arising below the upper cell-angle; the areole is very short, from its end vein 7 arises separated from the two next stalked veins; the basal two thirds of the ♂ antennae are set with pectinations gradually decreasing in length, basally with 2 large scale-hair tufts; palpi rather long, porrect, distinguished by the long flat leaf-like scale-hairs of the middle joint, the terminal joint being also rather long.

Type of genus: *P. triangulum* sp. n.

P. triangulum sp. n. (147 a) has whitish forewings strewn with olive brown, most densely so in the upper *triangulum*. half of the marginal area; a small olive brown spot in the base of the costal margin is traversed by the broad notched whitish subbasal line, a short thick black oblique streak is below it, obliquely rising distally from the base of the inner margin to the submedian fold; behind the costal-marginal spot follows a very large triangular spot the distal point of which almost reaches the apex, the lower point resting on the submedian fold behind its centre; it is distally edged by a white line, strongly mixed with white in the costal-marginal part and traversed by oblique costal-marginal streaks; a yellowish-white longitudinal spot is in the distal cell-end and, behind it and connected with it, a horizontal crescent, both being edged with black below; two darker subterminal dentate lines bordered with whitish, an irregularly scalariformly notched fine blackish submarginal line. Hindwing brownish-grey, darkened towards the margin, with light fringe. Described according to several ♂♂ labelled: "South America." Type in the Senckenberg Museum.

49. Genus: **Hippia** Mschlr.

A larger genus of species which are partly difficult to separate. Antenna of ♂ tuftedly ciliated, of ♀ plain, the terminal joint of the palpus thin and long. The forewing with a pointed apex and a broadly rounded

distal margin does not differ in the neuration from the preceding genus except that all the cellular veins arise without a stalk or on a very short stalk at most.

Type of genus: *H. mumetes* Cr.

- mumetes.* **H. mumetes** Cr. (= *albopicta* Dogn.) is a species known long ago and has been assigned to various genera. Forewing olive grey in the basal third, at the costal margin and in the inner-marginal half, distally with a broad white band enclosing a small black apical dot; inner margin dusted with brownish; the fine black dentate double transverse lines are quite indistinct in the upper portion of the wing and partly broken up into dots. Hindwing brownish-grey with lighter fringe. Expanse of wings: 33 mm. Guiana.
- pulchra.* **H. pulchra** Btlr. is somewhat like *mumetes*, but the forewing exhibits beside the white subterminal band also a broad white costal-marginal stripe which is strewn with brown towards the costal margin and connected from the apex with the subterminal band by a white oblique line; the black apical dot is still larger here; the inner margin is contrastingly dusted with pinkish brown, the black notched double lines are much more distinct; a large white spot is at the cell-end; hindwing greyish-brown. Ecuador.
- punctillum.* **H. punctillum** Dogn. (147 a) has greyish-brown forewings without distinct transverse markings, with a black dot before the cell-end and two behind it, the distal lower one of which is centred reddish-yellow; several reddish-yellow dots and streaks on the submedian fold and behind the cell, and a subterminal row. Hindwing brownish, lighter towards the base, with reddish-yellow fringe. French Guiana.
- insularis.* **H. insularis** Grt. (= *lignosa* Mschlr.) (~~147a~~) introduces a group of very similar species which are very difficult to separate. Forewing olive grey, thickly strewn with brown, with double dentate black transverse lines, the posterior one broken up into a double row of black dots and followed by a yellowish shadow; a dark streak at the cell-end is bordered with light only inwards and is distally followed by two black dots above each other behind the cell; the apex is feebly parted by light, the light undulate line is shaded darker inside, with small dark internerval spots before the margin. Hindwing brownish-grey; Cuba.
- vittipalpis.* **H. vittipalpis** Wkr. is probably homogeneous with *insularis* Grt. and seems to be merely a somewhat greyer form; DYAR combines it with *insularis* and *packardi* and leaves *vittipalpis* as the legitimate name.
- mandela.* **H. mandela** Drc. (= *nigricaput* Dogn.) (147 b) has brown wings strewn somewhat darker especially in the ♂, with double black transverse lines, the posterior one broken up into rows of dots, which are separated by yellowish dots, and preceded by a more or less complete row of internerval dots; a dark streak in a light ring is at the cell-end, an anal-angular blotch of darker strewing is before and below it; the apex is obliquely parted by light yellowish-white, the subterminal line is brownish, small blackish spots surrounded by a lighter colour are before the margin. Hindwing blackish with light fringe. The head, collar and mesothorax are blackish-brown in the ♂, light reddish-yellow in the ♀. Widely distributed in Mexico and Central America.
- packardi.* **H. packardi** Morris (147 b) is smaller and stouter of a greyer, less brownish colouring, without the subbasal line, with a small blackish spot proximally bordered with whitish, in the centre of the cell; the light apical blotch is more distinct, more sharply shaded with black below, the postmedian line is more linear, deeply concave inwards behind the cell-end streak. Texas.
- matheis.* **H. matheis** Schs. is also very similar, larger, darker greyish-brown, more plainly marked, with but one double anterior and posterior transverse line each; apical third yellowish-white, striped brown, with an undulate dark marginal line. Brazil (Petropolis). The species deviates somewhat from the genus, since a raised tuft of scales is at the base of the antennae.
- salandera.* **H. salandera** Schs. (147 b) is very similar to *matheis*; forewing dark velvety brown with a light yellow stripe from the centre of the cell to the distal margin above vein 6, interrupted on 5 by a brownline, subcostally strewn with lilac and brown, with a preapical black dot; basal third likewise densely strewn with lilac grey below the cell, the lower anal third of the distal margin light brownish; the anterior transverse lines are quite absent, the posterior one and the submarginal line are very indistinct. Hindwing dark brown. British Guiana; Amazons; Eastern Peru.
- pronax.* **H. pronax** Dogn. (147 b) has the same distinction of the antennae as *matheis* and resembles it except the apical spot. Forewing brown with subbasal and anal brightenings; the anterior transverse line is marked by 4 lighter lunulae, the cell-end streak is also light and only sometimes bordered with blackish; the postmedian line is indicated by double rows of black vein-dots, the undulate line by small brown, lighter ringed internerval spots; the ochreous apical spot begins in the upper half of the cross-vein, despatching a short hook towards vein 4 and narrowing down as far as the apex. Hindwing brown with light fringe. French Guiana, Eastern Peru; Trinidad.

H. undilinea *sp. n.* (147 b) is somewhat similar to the preceding species; head and thorax yellowish-grey, *undilinea*. only the base of the collar is blackish-brown. Forewing light brownish pink, only at the costal margin narrowly deep blackish-brown, and more widely so below the light subcostal line from the centre of the cell to the margin, intermixed with lilac white and greenish-yellow scales in the anal half of the margin and in the basal third; the light brownish-pink subcostal stripe below the dark costal margin is bordered by a yellowish-white line towards the blackish-brown area, which line begins in the centre of the cell, turning at the cell-end upwards around a dark round convexity, whereupon it extends straightly for some distance and then forming two steps terminates into the apex; the postmedian line is only visible towards the light anal area in some sagittiform pointed arches, behind it follow black subterminal angular streaks. Hindwing greyish-brown with light reddish-yellow fringe. 1 ♀ from Chuchuras (Eastern Peru). Type in the Berlin Museum (Coll. STAUDINGER).

H. schausi *Dyar* (146 k) chiefly differs from the similar *matheis* in the purer white costal band being *schausi*. fadedly continued to the base of the wing, bending in the centre of the cell, where it leaves the costal margin, downwards to the base of the inner margin, where it is more intensely strewn with brown than apicad; forewing greyer, shaded with blackish at the base of the costal margin, in the median area and anally; white vein-dots are behind the quite indistinct postmedian line. French Guiana to Peru.

H. astuta *Schs.* (= *anica* *Drc.*) (147 c) approximates *mandela*; it has longer, lighter, more brownish *astuta*. forewings, the costal-marginal part distinctly brownish-red, the inner-marginal part more yellowish-grey, all the transverse markings broken up into dots, with larger blackish spots before and behind the cell-end and inwards to the anal angle; the yellowish-white apical spot is very small, enclosing a black dot, the veins subapically are fine whitish-yellow. The larger ♀ is more monotonously blackish-grey, the inner marginal part not much lighter. Mexico to Venezuela, Peru.

H. undulata *Drc.* resembles *astuta*; forewing reddish-brown, the transverse lines are developed into more *undulata*. complete fine lines, only partly divided into small spots, a larger brown postcellular spot. In contrast with *astuta*, the ♀ is somewhat lighter with more distinct markings. Colombia.

H. cinga *Drc.* is likewise allied to *astuta*, larger, darker blackish-brown, strewn with black, with a long *cinga*. light apical spot strewn with grey and extending to the centre of the costal margin, the other markings as in *undulata*, but much more indistinct, only a submarginal row of brown light spots being more distinct. Hindwing dark brown with light fringe. Peru.

H. gracita *Schs.* Forewing grey, dusted with brown at the costal margin as far as the centre, broadly *gracita*. white behind it with light grey internerval shadows, with black double transverse lines, the posterior line broken up into rows of dots, with black and white dots behind them; an oblique dark streak at the cell-end and a white line to the light costal part which is bordered below by a triangular dark shadow; the undulate line is dark brown, black spots are at the anal angle; as in *mandela*, an oblique blackish shadow is in and below the cell-end. Hindwing blackish-brown, yellowish basally and at the inner margin. Expanse of wings: 39 mm. Guatemala.

H. talae *Berg* is externally somewhat like *mandela*, but the species is smaller, with narrower wings, the *talae*. colour of the forewings is a much more monotonous grey, less strewn with brown, with somewhat more distinct transverse lines; the cell-end streak, however, is very faded, without the light bordering on both sides; the apex is not parted by light here, the black submarginal spots are not in light rings; the light notched undulate line is not shaded darker on the inside and not very prominent. Hindwing brownish-grey. Argentina.

50. Genus: **Symmerista** *Hbn.*

Very closely allied to the preceding genus, also in the scheme of markings, but the terminal joint of the palpus is short and the ♂ antenna pectinated.

Type of genus: *albifrons* *Abb. & Sm.*

S. albifrons *Abb. & Sm.* (147 c) is a difficult species owing to the variety of its forms. The typical North- *albifrons*. American species is ash-grey, head and collar as well as mesothorax light reddish-yellow, turning whitish in front, mesothorax more or less brown; the forewing is strewn darker, shaded darker blackish in the median area and below the light apical stripe; the subbasal one of the black transverse lines is single, forming two bows, the anterior line is double, removed far into the middle, filled with whitish, the posterior line quite indistinct, shadow-like; the cell-end streak is red-brown, surrounded with light reddish-yellow; the yellowish-white costal-marginal stripe extends below with a small fine point to the antemedian line, being broadly dusted with lilac grey above it and forming, behind the cellular spot, a triangular pointed dent, which is turned downwards, and besides pointed distal dents on the two lowest subcostal branches; a fine black dentate line is before the distal margin, being almost scalariform below the centre. The whitish hindwing is smoky, darker in the ♀. This form occurs from Canada to Mexico. — f. **albicosta** *Hbn.*, occurring from New York to Florida, is somewhat smaller, *albicosta*. the white costal-marginal band is broader and shorter, and terminates obtuse at the apex; it ends inwards not pointed on the discal fold, but broad along the antemedian line in the cell, the dent behind the cell-end spot ends rounded below, not pointedly triangular, the cell-end is filled with a deeper red-brown colour, and the

- suavis*. arches of the submarginal line are much flatter. — f. **suavis** Barnes is the western form from Colorado; the ground-colour below the costal stripe behind the cell is much darker here, the cell-end spot much thicker, shorter and deep black; the collar is dark greyish-black, the ♂ hindwing white, only at the base of the fringe somewhat smoky, but like the type in the ♀; on account of its antennae being somewhat longer pectinated, the author considers it to be a distinct species. — Moreover, 3 well differentiated insects are before me from Mexico, partly in numbers, but as only the ♀♀ are known to me for the present, it cannot be decided whether they are distinct species, for which reason we range them here as forms of *albifrons*: — **jalapae** f. nov. (147 c) is a large, very light and delicately lilac grey form, not strewn darker, without any transverse markings except the fine double antemedian line which extends sharply distally below the median vein, then on the submedian fold more than 1½ mm inwards on to the inner margin; the costal-marginal stripe is very purely white below and bordered below by a deep and broad blackish-brown colour with a chestnut-red reflection, the dent behind the discal spot is short and broad triangular; the pointed arches of the submarginal line are transformed below the centre into fine black oblique streaks turned inwards above. Head and collar light reddish-yellow, abdomen and hindwings light brownish-grey. Jalapa. — **difficilis** f. nov. (147 d) differs from *jalapae* in the forewing being coarsely strewn with olive grey especially before and behind the lighter median area, the basal area is purely white, it contains the subbasal line forming two high pointed arches; the antemedian line forms quite equably rounded arches, its interior portion is olive grey, only the distal portion being thick and black, red-brown near the cell, the postmedian line is likewise distinct and forms distinct blackish lunulae interrupted on the veins; the area below the costal-marginal stripe is only slightly shaded with yellowish-grey, the submarginal line does not form any pointed arches, but only very flat uniform dull brown lunulae interrupted by the veins. Fringe more undulate and speckled light and dark, more uniformly rounded and unicoloured lilac grey in *jalapae*. Jalapa. The types of these two forms are in the Coll. DRAUDT. — **zacualpana** f. nov. (147 d) is the largest and darkest form, dark slaty grey, without any markings like *jalapae*, of the antemedian line only one double arch is visible below the cell, the posterior line is partly indicated by shadow-like black strewing, a black streak above it in the cell-end, which is strewn with red-brown, before the deep red-brown discal spot in a reddish-yellow ring; the yellowish ochreous costal-marginal stripe is somewhat more whitish below and only extends to the cell-end, in all the other forms it enters the cell, it forms strong triangular dents downwards, all of which are close together, and it is spotted cinnamon brown before the apex in the cellular spaces, crossed by the silvery white veins; towards the ground of the base it is feebly bordered with red-brown, towards the costal margin it is intensely dusted lilac grey. Hindwing less brown than in the other forms; the submarginal line forms flat arches, thickened between the veins. Zacualpan. Type in the Coll. DRAUDT. — The adult larva is orange brown or red with greyish-white dorsal and lateral bands which are finely longitudinally striped black, and a red protuberance on the 11th segment. It lives on oak and is gregarious in its youth.
- odontomys*. **S. odontomys** Dyar (147 d) is also extraordinarily similar to the preceding forms, but surely a distinct species on account of the ♂ antennae being at least thrice as broadly pectinated. Colour purple grey as in *zacualpana*, all the transverse markings distinct as in *albifrons*, the antemedian area lighter whitish-grey, the costal margin narrow and sharply darkened; the narrow and long yellowish-white costal-marginal stripe extends in its entire width to the uppermost round arches of the double antemedian line, the dent behind the small dark cell-end streak surrounded by reddish is very small and short, the next dent only follows shortly before the angular arches of the submarginal line. Head and collar dark brown, hindwing dark greyish-brown. Mexico (Zacualpan).
- tlotzin*. **S. tlotzin** Schs. (147 d) lacks the characteristical whitish-yellow costal-marginal stripe of the preceding species; forewing light grey with rather straight black transverse lines, two through the centre and one behind it, the submarginal line extends similarly as in the preceding species; between them, the wing is traversed by several notched shadowy stripes. Hindwing white, shaded with brown at the costal and distal margins. Described from Mexico.
- sigea*. **S. sigea** Schs. Body and forewing as in *tlotzin*. Hindwing white at the base and inner margin, suffused with light brownish, with brown veins, dark brown at the distal margin from the centre of the costal margin, narrower analwards, fringe white. Expanse of wings: 36 mm. Coary (Amazons).
- corcova*. **S. corcova** Jones. Forewing reddish ochreous brown, dusted with lilac, with double red-brown transverse lines, the interior part of the anterior line being very dark, enclosing a white spot at the inner margin, shaded with violettish-brown on both sides, the distal shadow extending at the inner margin as far as the anal angle, the posterior line strongly dentate, filled with a lighter colour; a dark V-shaped spot is at the cell-end, and red-brown submarginal spots surrounded by a lighter colour, those above veins 3, 6 and 7 being the largest. Hindwing yellowish reddish brown, darker at the costal and distal margins. Expanse of wings: 35 mm. Brazil (Rio de Janeiro).

51. Genus: **Arhacia** Herr.-Schäff.

This genus which used to comprise part of the genus *Lirimiris* is now confined to 4 large species with tuftedly ciliated ♂ antennae, feeble, rather short palpi with a somewhat longer second joint. Forewing long

and narrow with a completely rounded interior angle, a very long narrow arcole from the apex of which the veins 7 and 8 arise stalked, 10 arises above before its end. Hindwing as in the preceding species.

Type of genus: *A. combusta* Herr.-Schäff.

A. combusta Herr.-Schäff. (147 e) has light reddish yellowish-brown forewings with narrow dark red- *combusta*. brown margins, a scarcely darker longitudinal stripe through the cell as far as the margin, interrupted on the cross-vein by two reddish-brown transverse streaks which are bordered with light; a narrower darker, more olive longitudinal stripe below the cell stops in the subterminal area before a small black spot, with traces of a deeply dentate postmedian line before the margin. Hindwing lighter than forewing, dark red-brown at the anal angle with light lines. Brazil.

A. imitans Schs. is exactly like *combusta*, but easily discernible by the brown hindwing being only *imitans*. yellowish-white at the costal margin and in the upper half of the cell, and the forewing showing intermixed olive green colour before the fringe. Expanse of wings: 57 mm. Costa Rica.

A. lignaris Schs. is also very similar to the two preceding species, but easily separable from them by the *lignaris*. dark greyish-brown shading behind the cell as far as the margin between the veins 4 and 6; moreover, the frons is dark brown, only the vertex light. Hindwing light as in *combusta*. Expanse of wings: ♂ 54, ♀ 73 mm. Costa Rica.

A. postbrunnea Roths. likewise resembles *combusta*; forewing reddish-yellow, with an olive tint, brown *post-brunnea*. at the margins, with a brown longitudinal shadow below the median vein and a reddish-yellow reniform macula at the cell-end, enclosing two darker lines; the darker postmedian line is indistinct, double and filled with a lighter colour; 2 fine pink lines in the brown margin, a broader reddish-yellow line before them. Hindwing sooty blackish-brown, reddish-yellow with an olive tint in the basal two thirds of the costal margin, the basal third and the inner-marginal area; two pink lines at the anal angle. Expanse of wings: 56 mm. French Guiana.

52. Genus: **Lirimiris** Wkr.

Extremely similar to the preceding genus, only separated by the long double pectinations of the antennae, the apical quarters remaining plain. The apex of the long and narrow forewing is often somewhat truncate, the distal margin slightly concave above the anal angle. The mark of distinction hitherto assumed, i. e. the separate origin of veins 3 and 4 on the hindwing, has proved to be variable.

Type of genus: *L. lignitecta* Wkr.

L. lignitecta Wkr. (= *argentifera* Drc.) (147 d, e) has white forewings, the distal three quarters of the *lignitecta*. costal margin being deep blackish-brown; excepting the basal area, the larger inner-marginal half is scaled olive grey, a large clover-shaped reniform macula being open above, composed of erect scales, is at the cell-end, traces of a deeply notched dark posterior transverse line and of a white submarginal line are present. Hindwing white with a narrow brown margin. Widely distributed from Mexico to Brazil. — By the kindness of Mr. ARP there are large specimens before me from Brazil, which, in contrast with the Mexican specimens, have quite blackish-brown hindwings, — in the type they are white as in the ♂ —, the forewing being tinged with pink, the reniform macula of a yellow tint, and the collar intensely ochreous, dark brown in the typical form; the form may be named: — **arpi** f. n. (144 e, f); it is probably a distinct species. *arpi*.

L. auriflua sp. n. (147 f) is at once recognizable by the bright orange anal end. Forewing very narrow, *auriflua*. marked very much like the preceding species; forewing white, with a narrow blackish-brown stripe from the basal third of the costal margin, interrupted in the distal third by 3 white small costal-marginal hooks, dusted with light brown in the inner-marginal half into which the large white reniform macula extends; all the linear markings are very indistinct, a short black longitudinal streak in the basal part below the cell and short black, very oblique postmedian streaks, especially towards the inner margin more distinctly bordered with white and double here. Hindwing distinctly triangular, diaphanous white, narrowly bordered with blackish-brown only at the costal margin and analwards, the inner margin clad with smoky brown hair. Several ♂♂ from Brazil (Rio) and Eastern Peru (Chuchuras). Type from Rio in the Berlin Museum.

L. truncata Herr.-Schäff. (147 f) is the chief representative of an extremely difficult group, since my *truncata*. examinations have yielded no fewer than 3 specimens in Mexico alone, which are scarcely distinguishable externally, but which can be distinctly separated by the genital organs. As the type of this species I consider the form which occurs most commonly and is most widely distributed in Mexico. The costal-marginal part of the forewing is light brownish ochreous, warming into white towards the blackish-brown inner-marginal part, with 2 or 3 small brown or blackish dots at the cell-end; the apical area is slightly brownish and encloses a few fine black wedges and small light costal-marginal hooks; a light line before the margin, then follows a black fine line, another black line is at the base of the brown fringe. Hindwing white in the disc, smoky on the veins and margin, with smoky grey hairs along the inner margin. The ♀ has broader wings, the hindwing is quite greyish-brown. The hindwing of this species is shortly triangular and rather deeply concave before the anal angle.

The distal end of the valve is extended into a long fine point, almost like the beak of an ibis, which proceeds with a slight curve, almost geniculated in an angle of 75 degrees and is very intensely chitinized blackish-brown, the median lateral edge bearing a slight very bristly hunch; the penis is long and thin, chitinized deep blackish-brown. Common in Mexico (Orizaba, Misantla etc.).

inopinata. **L. inopinata** *sp. n.* (147 g) is somewhat smaller than the preceding species, of a somewhat greyer effect in its colouring, the light costal-marginal part being not so yellowish-ochreous, more brownish-white; at once discernible by much darker, blackish-grey hindwings, all the rest agreeing exactly with *truncata*. Hindwing broad, well rounded. The distal end of the valve is only of half the length and more than double the width of that in *truncata*, not geniculated, but bent in a uniform slight curve; in the centre of this curve there is inside a triangular pointed projecting dent with some bristles; the median lateral edge bears no hunch, but it is almost rectilinear; penis like that of *truncata*. Colima, numerous ♂♂ are before me, type in the Coll. DRAUDT.

guatemalensis. **L. guatemalensis** *Rothsch.* (147 g) is still more similar to *truncata*, larger, with relatively narrower forewings which are somewhat more convex before the apex at the costal margin, the slight projection of the distal margin on vein 4 seems to lie a little higher, and the part of the distal margin below it forms almost one straight line with the inner margin. Hindwing longer and broader, the concavity before the interior angle is very slight. The colour of the costal-marginal part is also less yellowish than in *truncata*, more ivory white. The colour of the hindwing is intermediary between the two preceding species, though much more smoky than in *truncata*. The genital organs are quite different, the valve on the whole at least twice as long as in the preceding species and all the parts very feebly chitinized light yellow; the distal end is produced almost in the shape of a vulture's head, its neck being slightly S-curved, so that it cannot be mistaken for any of the preceding species; the penis is also only feebly chitinized, shorter and comparatively thrice as thick as that of the preceding species. Guatemala and Mexico (Zacualpan).

supertruncata. **L. supertruncata** *Dogn.* is also very similar to the 3 preceding species, but much larger, its expanse being 77 mm. The border between the light costal-marginal part of the forewing and the dark part is not rectilinear, but it forms a dent before the lower cell-angle and extends from there to the margin on vein 7 and not on 5 as in the preceding species; the dark ground-colour brightens between 2 and 3 towards the margin as far as the black strongly dentate subterminal line. Hindwing covered with blackish scales, with a red-brown spot at the anal angle. Peru.

chimaera. **L. chimaera** *Rothsch.* is another ally of the very difficult *truncata*-group, with much longer, narrower and more curved forewings, the ♂ pectinations being extraordinarily long, red-brown. The costal-marginal part is light reddish-yellow, a longitudinal stripe below the median vein, the distal third of the costal margin and a subterminal band are rusty red, the interior part is chocolate brown dusted with olive. Hindwing dull white, dingy grey on the veins and inner margin, rusty brown at the margin and anal angle. Expanse of wings: 108 mm. South-Eastern Peru.

gigantea. **L. gigantea** *Drc.* has an expanse of almost 10 cm and is one of the largest of the similar species; forewing dark reddish-brown with a broad yellowish-white costal-marginal part and a double red-brown, strongly notched submarginal line. Separable from *truncata* by its larger size and white hindwings which are only feebly smoky at the costal margin, apex and inner margin, with 2 black spots at the interior angle and an interrupted yellow line at the margin. Peru.

corina. **L. corina** *Schs.* The broad blackish-brown shadowy stripe separating the light reddish-yellow costal-marginal part from the dark violettish-brown inner-marginal part begins at base of the costal margin, traverses the cell as far as below the median vein and terminates at the margin within the veins 4 and 6; the veins are marked darker here, the apical third of the costal margin is dusted with light brown; double transverse lines are traceable, a subterminal brownish-grey shadow is darkest in the lower half; a light reddish-yellow line at the margin, then an olive brown line. Hindwing whitish, smoky on the veins and margin, quite greyish-brown in the ♀. Expanse of wings: 35—42 mm. Costa Rica.

punctata. **L. punctata** *Dogn.* is somewhat similar to *corina*, still smaller, the forewing quite light brownish without the darker inner-marginal part, but the subterminal area between and above the veins 2 and 3 is whitish; the black longitudinal shadow is interrupted in the lower cell-angle by a white triangular dot and ends rounded postmedianly, bordered above by a black longitudinal streak between 5 and 6, which then turns to the apex before which there is a black dot at the costal margin. Hindwing white, broad at the costal and inner margin, narrowly brownish at the distal margin. Expanse of wings: 32 mm. Brazil (Joinville).

elongata. **L. elongata** *Schs.* (147 h) is a very large species with long, narrow wings being almost falcate at the apex, with a very oblique distal margin, reddish yellowish grey with a violet tint, shaded with dark grey in the basal half below the subcosta, with black dots before and behind the cross-vein; a grey shadow above vein 4 extends to the margin, the apical third of the costal margin is dusted with brownish; a fine dark postmedian line is irregularly marked. Hindwing greyish-black. — f. **postpallida** *Rothsch.* differs from the Peruvian type in its white hindwings and less grey forewings which are more suffused with reddish-yellow; this form has been described from Costa Rica. — f. **orientalis** *Rothsch.*, from Guiana and the Amazons, exhibits the forewing suffused with yellowish reddish-brown; hindwing darker than in *elongata*, but of a somewhat more yellowish tint.

L. euribya *Drc.* (147 g) is very similar, but much smaller, with a straight costal margin; forewing light *euribya*. yellowish reddish-brown, lightest at the apex and distal margin, with a dark brown longitudinal line through the wing from the base into the apex. Hindwing blackish-grey, darkest at the inner margin and apex. South-Eastern Peru.

L. fascis *Schs.* (147 h) introduces another group of species which look very much like *Arhacia combusta fascis*. from which, however, they are at once discernible by the antennae being strongly pectinated also in the ♀. Forewing light brownish-yellow, narrowly red-brown at the margins, with a lighter central line before the large reddish-brown reniform macula, the cell shaded darker olive and surrounded by a lighter border; traces of darker double transverse lines. Hindwing greyish-brown, narrowly yellowish at the margin, with double red-brown lines and a dark anal spot parted by white. Mexico to Brazil.

L. meridionalis *Schs.* (147 h) is considerably larger and darker than *fascis*, otherwise very similar; *meridio-* forewing olive brown, darker at the costal margin, dusted with red-brown in and below the cell. Hindwing *nalis*. darker blackish-grey with a double black marginal line. British Guiana.

L. lemoulti *Rothsch.* (148 a) is smaller and much darker than *meridionalis*. Head and thorax dark *lemoulti*. brown like the forewing, basal part somewhat lighter with very high pointed arches of the antemedian line, otherwise marked very much like *meridionalis*, the postmedian line more distinctly prominent than dark wedges which are distally bordered with light. Hindwing deep blackish-brown with traces of a lighter postmedian band, and a rusty brown anal spot bordered with black inside and outside. Guiana; the Berlin Museum contains also a specimen from Pará.

L. mirabilis *Rothsch.* (148 a). This peculiar animal is not to be mistaken for any other species, the *mirabilis*. long narrow curved forewing is concave in the lower two thirds of the distal margin; the colour is whitish reddish-yellow, slightly dusted brown in the distal half, with a large olive brown spot at the cell-end, enclosing a light reniform macula from which a light stripe extends below the apex; the distal half of the costal margin is sooty blackish-brown, with small chocolate-brown apical spots; a feeble dentate double postmedian line is visible. Hindwing white, brownish at the margin of the ♀. Peru, Venezuela.

53. Genus: **Arpema** *Schs.*

The genus contains only two large very similar species with broader wings than the preceding genus. Palpi and antennae as in the latter; vein 5 of forewing arises directly above the centre of the cross-vein, 6 before the centre of the areole from the end of which all the subcostal branches except the uppermost arise; the cellular branches of the hindwing arise without stalks and not separated by twos from the angles of the cell, the costal vein branches off from the subcostal vein before its centre.

Type of genus: *A. megalopia* *Schs.*

A. megalopia *Schs.* (= *bucephaloides* *Rothsch.*) (148 a). Forewing leaden grey in the small basal area, *megalopia*. bordered with white, covered behind it with very coarse white scales which are brown at the ends, greyer in the narrow median area; behind it follows a slightly distally concave white postmedian line which is edged with reddish cinnamon outside and borders on the darker lilac brown subterminal area; marginal area light violet-brown, traversed by two undulated lighter lines. Hindwing red-brown. Brazil.

A. phaleroides *Rothsch.* (148 a) is very similar to *megalopia* and differs in the triangular violettish-brown *phaleroides*. basal area which is distally bordered by a white oblique line; the dark subterminal area is lighter and narrower and is not bordered inside by such a distinct white line. Hindwing somewhat lighter. West Colombia; Peru.

54. Genus: **Cerura** *Schrk.*

Separated from the preceding genera by a very much shorter areole of the forewing, vein 6 arising almost from the end of the areole, 7 and 8 arising stalked from it. Vein 6 of hindwing stalked with 7. Antennae pectinated to the ends, palpi short. As to further particulars and the biology of this genus occurring also in the palaearctic region we refer to Vol. III, p. 285.

Type of Genus: *C. furcula* *Schrk.* from Europe.

C. scitisscripta *Wkr.* (= *platea* *Schs.*) (148 b) is the well-known American species with white forewings, *scitisscripta*. two antemedian and three postmedian black dentate transverse lines, the posterior one fourfold at the costal and inner margins, with a ring-shaped cellular macula in the centre. Hindwing white with black marginal dots. — f. **multisscripta** *Riley* is a somewhat darkened form, the transverse lines being filled with black scales, with *multi-* blackened hindwings. Larva of the usual pussmoth shape, light green, head and neck-spot on the thoracal *scripta*. segments blackish-brown, the saddle-spot on the dorsum lighter brownish, dusted almost entirely bluish-white

above. It lives on willows and poplars and on wild cherry. The darker form occurs in the Northern States, whilst the white form is found from Florida and Georgia to Kansas, also in Mexico.

candida. **C. candida** Lintn. (148 b) resembles the preceding species from which it only differs in the white thorax and entirely white hindwings without any black marginal dots. It was formerly regarded as a form of *scitisscripta*, but it is considered a distinct species now. From Florida.

rarata. **C. rarata** Wkr. (148 b) is relatively near to the preceding species. Forewing silvery white, with 2 antemedian and 3 postmedian black dentate transverse lines, the anterior ones distantly separated and enclosing two black rings, one in the cell, one at the inner margin; above them, at the costal margin, there is a small V-shaped mark, a similar more distinct mark is subapical. Hindwing white, with a small black anal spot which may also be absent. The type is widely distributed and occurs already in Texas; farther to the south the species has been observed as far as Peru, in most variable forms.

tehuacana. **C. tehuacana** sp. n. (148 b), in my opinion, is not a form of *rarata*, but a distinct species; more robustly built, more thickly scaled chalky, not so lustrous silky; all the black markings considerably thicker, of a more oblique course and partly confluent subapically and in the centre of the inner margin; thick internerval dots at the margin. Mexico (Tehuacan), types in the Coll. DRAUDT.

presidio. **C. presidio** Dyar is very similar to *tehuacana* and discernible by the olive grey filling of the interior band which lacks the inner-marginal ring; a black transverse line in the cell is surrounded by a circular line. Hindwing white, blackened at the base of the inner margin, with 2 oblique black lines at the anal angle and black-spotted fringe which is invariably purely white in *tehuacana*. A large species with an expanse of 44 mm. From Mexico (Presidio).

xiconia. **C. xiconia** Dyar (148 c) is most closely allied to *rarata*, but smaller and more delicate, without the ring in the cell. Hindwing white, only very tiny black dots in the fringe. Mexico (Zacualpan), taken in November.

trigonostigma. **C. trigonostigma** Dyar (148 c) has hardly any markings, it is white with fine black spots intermixed with yellowish scales; a small triangular spot between the subcosta and inner-marginal vein, a small bipartite spot in the centre of the costal margin, and one opposite at the inner margin, a submarginal line from the apex to vein 4 and a triangular spot at the anal angle; black internerval dots at the margin. The abdomen is intermixed with black hairs. Mexico (Colima), taken in June.

purusa. **C. purusa** Schs. Head and thorax white, the latter with a black dorsal line and 4 small spots; abdomen black above, base, anal segment, sides and ventrum white. Forewing silvery white, markings similar as in *trigonostigma*; a triangular basal spot, a small one in the centre of the inner margin, filled with reddish-yellow, a short line behind the centre of the inner margin, a round spot filled with reddish-yellow in the centre of the cell, and a forked line above it at the costal margin; distal line between 4 and the costal margin thick black, close behind it another line between 6 and the costal margin; reddish-yellow scales between 8 and 6 extend downwards along the first line; small black lunae at the margin. Hindwing white, diaphanous in the disc. Expanse of wings: 34 mm. Brazil (Rio Purus).

annulifera. **C. annulifera** Berg (148 e) looks somewhat like *rarata*, but the forewing is olive grey, with two antemedian and postmedian notched black transverse lines, the two anterior ones likewise distantly separated and with 2 black rings, one in the cell and one at the inner margin, the small V-spot at the costal margin is absent; of the undulate line only darker shading on the inner side is present, and a large black subapical spot at the costal margin. Hindwing dark blackish-grey, fringe speckled black and white. Argentina.

laqueata. **C. laqueata** Schs. (148 e). Forewing silvery white, with 4 antemedian and two postmedian black undulated lines, another short line from the costal margin behind the most exterior line; a large irregular cellular spot projects somewhat obtusely outside below; a straight line at the margin below the apex, short streaks below it are directed obliquely distad downwards. Hindwing white with a dark apical spot, a dark-haired inner margin and small marginal spot. Costa Rica.

gonema. **C. gonema** Schs. (148 e) is distinguished by brownish-grey hindwings; abdomen above also dark brown, only the two last segments with white bands; forewing silvery white with 6 similar transverse lines as in *laqueata*, the basal one bifurcating towards the costal margin, the third confluent with a black cellular spot, another black spot in the cell-end is confluent with one below it. French Guiana.

argentina. **C. argentina** Dogn. is similar to *gonema* but smaller and with white hindwings; the basal transverse lines on the forewing are broken up into vein-dots, followed by a black cellular dot with a white pupil, and a small costal spot above it, the double postmedian line is removed farther subterminally, indistinctly black above the centre; the oblique marginal streaks are replaced by internerval dots. Abdomen black above, with a white anal end and ventrum. Expanse of wings: 27 mm. Described from Argentina.

argynnis. **C. argynnis** Schs. The white forewing exhibits behind the two interrupted basal transverse lines three rings: at the inner margin, in the cell and at the costal margin, one above the other and centred greenish yellow; the two double subterminal ones are somewhat faded towards the apex and intermixed with greenish-

yellow scales. Hindwing of ♂ white with a black inner-angular dot, brownish-grey in the ♀, the fringe speckled black. Expanse of wings: 31–33 mm. Castro (Parana).

C. rivera Schs. (148 d) is extremely similar to *argynnis*, but larger and with a thick black pupil in the *rivera*, inner-marginal ring. The ♀ has quite black hindwings with grey fringe. The abdomen beneath exhibits a series of black dots, the ventrum of *argynnis* is all white. Brazil (Rio de Janeiro, Castro, Parana).

C. splendens Jones is still larger than *rivera*, similarly marked as *argynnis*, separable by the single *splendens*, black postmedian line which is very broad at the inner margin and confluent at the apex with a black costal-marginal spot, a yellow line follows behind it and is widened like a spot at the inner margin between 4 and 6 and subapically; fringe white with black internerval spots. Hindwing of ♀ brown, darkened at the margin. Abdomen silvery grey, with blackish-brown bands. Expanse of wings: 48 mm. Castro (Parana).

C. bratteata sp. n. (148 d) is much slimmer than the allies, with a longer and much more oblique distal *bratteata*, margin; forewing silvery white, with two fine antemedian transverse lines submedianly connected like a Y, and a double postmedian line the dents of which between 2 and 4 are connected with the same dents of the subterminal line, forming a threefold line; the yellow spots show a golden gloss, the spot at the inner margin confluent from two; other golden yellow spots are behind the postmedian line, subapically and between 4 and 6; the ends of the veins are traversed by black, hindwing white, slightly black-spotted only at the anal angle. West Colombia (Rio Mieay), type in the Coll. NIEPELT; East Colombia (Rio Negro).

C. lancea Schs. (148 d) represents another type of marking similar to that of the allies of the palaearctic *lancea*, *vinula*. Forewing dull white, not silvery, with brown markings, the marginal area showing the strongly notched lines of *vinula*, as well as its long internerval wedges, while the black-pupilled ring-spot of *bratteata* is before the centre at the inner margin. Hindwing smoky black at the inner margin, anal angle and apex. Guiana, Colombia.

C. duonummenia Dyar (148 d) is a small species showing resemblances to the species of *Harpyia*; fore- *duonum-*
wing densely strewn black, so that all the markings are covered except the double postmedian line which is *menia*, filled with whitish and removed far towards the margin; its distal portion is thicker black except the part between 2 and 4; thick black internerval dots on the margin. Hindwing scantily scaled, grey with whitish fringe spotted black between the veins. Mexico (Tehuacan).

C. dandon Drc. (148 d, e) forms quite a different group. Forewing glossy silky white, tinged with *dandon*, brownish olive in the cell and behind it as well as submedianly, with thick velvety black spots at the costal and inner margins, partly connected by fine brown dentate lines. Hindwing white with a black anal-angular streak. Mexico to Brazil. The ♀ is much larger and has brown hindwings. — **grandis** Schs. (148 e) is a larger, *grandis*, more robust form with very thick black spots and internerval marginal dots. Brazil.

C. bikasta sp. n. (Maass. i. l.) (148 e). This very peculiar insect may be best inserted here, although *bikasta*, 7 and 8 of the forewing arise without a stalk from the apex of the areole; it may also belong to the genus *Eucerura* (p. 950). White, presumably darkened somewhat brownish by age; antemedian and marginal areas broad black, both defined towards the white median area and the white basal area by fine black double lines; a black discal streak at the cell-end. Fringe grey, traversed by black. Hindwing white with a black marginal line, the fringe towards the anal angle traversed by blackish; veins blackened in the apical part. According to 1 ♂ from Chile in the Berlin Museum (Coll. MAASSEN).

55. Genus: **Harpyia** Ochs.

We append here this most closely allied genus which is also biologically very similar. It differs from the preceding genus only in the entire disappearance of the areole which is often very small also in *Cerura*; thereby the origin of vein 6 is removed to the upper cell-angle or to a short stalk close behind it. The larvae exhibit the same shape as the other "pussmoth-larvae" and also the same habits.

Type of genus: *H. bicuspis* Borkh. from Europe.

H. borealis Boisδ. (148 e) is very similar to the palaearctic *bicuspis* with its white forewings which are *borealis*, somewhat smoky in the ♀, with a black, centrally strangulated median band the edges of which are sealed ochreous; rows of black dots are before and behind it, and a black subapical spot may be continued to the anal angle as a more or less complete band. Hindwing with a black central dot and marginal dots. Metathorax with steel-blue scales. — Larva green with a deep red-brown neck-spot and saddle-spot on the dorsum; these spots are contiguous and very broad without a distinct border between them and the green colour. It lives on wild cherry, also on poplar and willow. The species occurs in the Atlantic States.

- cinerea*. **H. cinerea** Wkr. (148 e) is whitish-grey on the forewing with quite faded markings, a faintly visible median band and rows of dots which are thickest at the costal and inner margins. Hindwing whitish; the marginal dots on both wings are distinct and strong. — The larva differs from that of *borealis* in the neck-spot being distinctly separated by reddish and bordered with yellowish-white; the dorsal saddle is twice strangulated towards the end of the body. On willows and poplars. In the whole United States from Canada to Mexico and Guatemala. The variability of the species is great: — f. **wileyi** Dyar is the name of the large whiter race from Montana and Colorado, occurring yet down as far as New Mexico, with very distinct marginal dots on both wings. — f. **cinereoides** Dyar, on the contrary, is more intensely darkened blackish, with somewhat more brownish orange strewn around the transverse lines, the rows of dots, owing to shading, are more united into lines. — f. **paradoxa** Behr, according to the type, is a very light, whitish form, its exterior resembling that of *nivea*, but invariably with distinct marginal dots and it never attains the size of *nivea*. It originates from California (Nevada Mts.). — f. **placida** Dyar is an almost purely white form, the rows of dots are united into transverse lines, scaled orange on both sides; hindwing likewise more purely white, fringe speckled black and white. Described from Florida.
- nivea*. **H. nivea** Neum. (148 e) is a rare species very near to *cinerea*, but large, purely white and without any black marginal dots; all the markings are very scanty. Type from Utah. Nothing is known of its life. — f. *niveata*. **niveata** B. & Benj., from Arizona, is also large with broad wings, but more distinctly marked; the median band is distinct, strangulated on the median vein, occasionally divided into two spots, with distinct rows of dots. — f. *meridionalis*. **meridionalis** Dyar is a somewhat smaller, more blackened form, more scantily scaled, the median area not prominently darker, the transverse lines as indistinct as in the nomenclatural type. Texas.
- scolopendrina*. **H. scolopendrina** Bsd. (148 f) resembles *cinerea*, but it has much more distinct markings, the median band is narrow, strangulated, greyish-black, with intensely ochreous scales at the margins and on the subapical spot; 3 distinct dentate lines, the most distal one merging into the subapical spot. The greyish-white hindwing exhibits one or two grey postmedian shadowy bands; marginal dots small, but distinct. A variable species: — f. *pluvialis*. **pluvialis** Dyar has somewhat broader wings with more blurred markings, the 3 postmedian lines are not clear, but more or less broken up into dots. Oregon, Vancouver, in May. — f. *albicoma*. **albicoma** Stkr. is somewhat lighter, the remarkably narrow median band is very much strangulated. The type originates from Denver (Colorado). — f. *aquilonaris*. **aquilonaris** Lintn. is a somewhat lighter, whiter form with less black markings; it is the typical form of the Eastern States from Canada to Colorado and New Mexico, in dry and hot districts. — f. *modesta*. **modesta** Huds., on the contrary, shows more yellowish forewings which are almost brownish distally; median band and subapical spot intense, scaled steel-blue. It occurs in the cooler districts of the Eastern States. — The larva resembles that of *cinerea*, the neck-spot is connected with the dorsal spot, bordered with yellow. On willow. Widely distributed in the United States, numbers of the typical form also from Mexico City.
- occidentalis*. **H. occidentalis** Lintn. resembles *scolopendrina* in colouring and marking, but the median band is very broad, black, strewn with white, with distinct black straight border-lines; the same 3 postmedian dentate lines, but there is distinct white filling between the two exterior ones; 5 black dots in the basal area, only 4 in the other species. Hindwing white with a large faded black median spot. In the Atlantic States from Canada to Texas. — Larva of a bright green colour, neck-spot separated from the dorsal spot, distinctly lilac, mixed with green above, the dorsal saddle somewhat lighter than the anterior spot; intensely purple brown lateral spots. It lives on willows in September, October, and develops in April until June.

56. Genus: **Betola** Schs.

Distinguished from the similarly built *Cerura* by only two thirds of the antennae being pectinated or also serrated and ciliated, the short porrect palpi, a tuft of scales on the head and a much longer abdomen with a split anal tuft. Forewing broader with a longer distal margin and somewhat dentate here, not entire. Neuration scarcely different from that of *Cerura*.

Type of genus: *B. aroata* Schs.

- aroata*. **B. aroata** Schs. (148 f) has very light brownish-yellow forewings, scaled steel-grey and white at the costal margin and above the anal angle, olive brown before the centre at the inner margin and behind the notched postmedian line, the olive brown colour projecting behind the cell and extending obliquely to the apex; a black dot in the lower cell-angle. Hindwing scantily scaled, white with a narrow brown marginal line. Venezuela, Brazil, Panama.
- typhon*. **B. typhon** sp. n. (148 f) is very similar to *aroata*, but more than three times its size (expanse of wings: 60 mm), apex of wing more pointed, all the colours clearer, more contrasting, costal margin light bluish-grey like the anal angle; the olive brown apical blotch, which is contiguous with the longitudinal blotch in the cell

in *aroata*, is distinctly interrupted behind the cell by a small light luna; an almost quadrangular bone-white spot is above the antemedian black submedian wedge-spot. Hindwing purely white, feebly smoky at the inner margin. Antennae as in *densissima*. From Brazil (Sa. Catharina), type in the SENCKENBERG Museum, Frankfurt on the Main.

B. densissima Dyar is very similar, only half of the antennae are pectinated, the markings are finer *densissima*, and more irregular, the costal margin is not shaded dark, the light longitudinal stripe is absent above the olive brown shadow which extends into the apex. Hindwing brownish-grey, darker on the veins, inner margin and distal margin. Expanse of wings: 43 mm. Guiana.

B. apostatica Dyar has no pectinated but serrated and tuftedly ciliated antennae in the ♂. The light *apostatica*, yellowish longitudinal stripe from the base into the apex is distinctly reddish-brown, not tinted olive as in *aroata*, the markings are more scanty, broader, the light apical blotch is absent altogether. Hindwing greyish-brown as in *densissima*; size somewhat larger. Expanse of wings: 45 mm. Guiana.

B. empirica Dogn. (148 f). Forewing yellowish greyish-brown, strewn with grey at the costal margin, *empirica*, with brown veins especially above the centre; a brown longitudinal line traverses the wing from the base of the submedian vein, where it is crossed by white, to the distal margin between 5 and 6, forming long distal dents below it, dusted whitish-grey apically. Hindwing white, brownish on the veins and margin. Mexico to San Salvador.

B. schrottkyi Dogn. (148 f) has ash-grey forewings with a broad yellowish longitudinal band from the *schrottkyi*, base to the apex; white dusting above the anal angle, the light longitudinal stripe with a double brown and black border within this dusting; cellular branches partly marked brown; fringe speckled brown and yellow. Hindwing white, feebly brownish on the veins and in a narrow marginal line. Colombia, Bolivia, Paraguay.

B. tucumanata Dogn. is similar to *schrottkyi* in the marking, but the wings are not ash-grey, but yellowish *tucumanata*, greyish-brown as in *empirica* with darker fine veins; the forewing is traversed by a broad yellowish longitudinal band which begins at the base and terminates into the distal margin a little below the apex; above the anal angle there is likewise bluish-white dusting enclosing a black double spot; at the cell-end a dark-edged reniform macula before which there is a small spot. Hindwing white. Argentina.

57. Genus: **Peroara** Schs.

Very near to the preceding genus, but without a tuft on the head, with longer haired palpi and with an entirely rounded distal margin of the forewing which shows the same neuration. Abdomen shorter and without an anal tuft. Only 3 species.

Type of genus: *P. sylvestris* Schs.

P. sylvestris Schs. (148 g). Thorax brown with white tegulae; abdomen bronze brown. Forewing grey, *sylvestris*, strewn with brown, darkest in the basal third, white at the cell-end, traversed by a brown line; the posterior transverse line and a broad subterminal shadow are white, both bordered with brown inwards, a large dark subapical spot at the costal margin. Hindwing smoky brown. Guiana, Colombia, Bolivia.

P. discovata Schs. is very similar to *sylvestris*, but separated by a different genital apparatus: the costal *discovata*, projections of the harpe are shorter, stouter and irregularly dentate, while in *sylvestris* they are altogether smaller and more gracile, long, slender and smooth. Forewing strewn more greyish-brown, less intermixed with white, traces of an anterior transverse line bordered with whitish inside; brown streaks behind the postmedian line, irregularly spot-like below the centre, distally bordered by the white subterminal line. Hindwing whitish, veins and inner margin yellowish, margin broad greyish-brown. Expanse of wings: 37 mm. Guatemala.

P. caterina Schs. (148 g) is similar to *discovata*, but larger and much darker; basal part of forewing *caterina*, dark brown, intermixed with white scales; inner margin more whitish at the base, the rest white mixed with brown, with two dark median lines and a white, strongly notched postmedian and subterminal line; a large blackish-brown spot in the cell, a white triangular spot mixed with reddish-yellow is behind it; a dark costal-marginal spot before the subterminal line, with black longitudinal streaks; fringe red-brown, crossed by yellowish on the ends of the veins. Hindwing light brown, darkened at the margin. Brazil (Blumenau).

58. Genus: **Gopha** Wkr.

The male antennae are shortly pectinated in the basal two thirds, serrated and tuftedly ciliated in the ♀; palpi oblique, with a long middle joint and a short terminal joint. Forewing broad with a straight costal margin and a sharp apex, slightly concave below it, the rest of the distal margin straight. Neuration as in *Lirimiris*. Only few species are known.

Type of genus: *G. mixtipennis* Wkr.

mixti-
pennis. **G. mixtipennis** Wkr. (148 g) has light brownish-violet forewings, dark brown at the costal margin, in the upper half of the median area and in a triangular area behind it, strewn with green scales, with black, finely dentated, double transverse lines filled with green, and a snow-white longitudinal streak below the costal margin between the antemedian and subterminal lines. Hindwing light brown, darker at the margin. Brazil.

inquieta. **G. inquieta** sp. n. (148 g) is extremely similar to *mixtipennis*; the white subcostal stripe extends quite into the apex and proximally it does not reach quite so near to the basal area which does not represent a light spot as in *mixtipennis*, but is brownish-white, coarsely strewn chocolate brown, with a white subbasal line bordered with dark brown inside, distally bordered by the antemedian line which forms strong arches; inner-marginal area as in *mixtipennis*, but much less strewn green; the whole median and postmedian area as far as the subterminal line is darker chocolate brown, without green; undulate line similar as in *mixtipennis*, but the small green dentate spots are smaller and distinctly bordered with blackish-brown on both sides. According to 1 ♂ from Surinam; type in the SENCKENBERG Museum, Frankfurt on the Main.

albipuncta. **G. albipuncta** Schs. is somewhat similar to *inquieta*, but it lacks the silvery white streak which is replaced by a large white spot at the cell-end, distally continued along vein 6; no transverse lines except the antemedian line, a series of green spots shaded with black inside are before the margin. Hindwing dark brown with lighter fringe. Expanse of wings: 34 mm. Brazil (São Paulo).

niveigutta. **G. niveigutta** Schs. is very closely allied to *albipuncta*, but much darker; forewing blackish, mixed with dark moss-green in and below the cell and at the apex; two submarginal rows of dark moss-green spots, a black postcellular shadow, small velvety black spots before the distal row; the silvery white spot of the same shape as in *albipuncta*, the veins strewn somewhat whitish. Hindwing blackish-brown with similar fringe speckled with reddish. Expanse of wings: 36 mm. French Guiana.

praxia. **G. praxia** Schs. which is doubtfully ranged here has purple brown forewings, parts of the inner margin dusted lighter, with a dark brown anterior transverse line filled with grey, and a white spot at the cell-end with a short hook-shaped inward continuation, followed behind it by a large blackish-brown spot with a row of smaller spots behind it towards the apex; white postmedian vein-dots and small submarginal brown lunae distally bordered with white. Hindwing blackish-brown, whitish towards the base and at the costal margin, with a dark white-scaled spot at the anal angle. Expanse of wings: 25 mm. Guatemala.

59. Genus: **Malupa** Schs.

Separated from the preceding genus by porrect palpi, tuftedly ciliated antennae and long narrow forewings with a convexity at the costal margin before the apex; hindwing of a triangular shape with rounded angles and a straight distal margin. Neuration as in the preceding genus, but veins 6 and 7 of hindwing on a longer stalk. Only 1 species:

Type of genus: *M. elongata* Schs.

elongata. **M. elongata** Schs. Forewing light olive brown, bright red-brown at the inner margin, the lower half of the distal margin, and in the distal half of the costal margin; a velvety brown basal ray below the median vein extends to the centre of the cell, light reddish-yellow dusting below it, distally to it the median vein is light, shaded with dark brown below; reddish-brown dusting at the cell-end, a light reddish-yellow line along the upper radial branch extends to the apex, another submarginal line to the interior angle. Hindwing whitish, dark brown at the inner margin and anal angle. Expanse of wings: 48 mm. British Guiana.

60. Genus: **Pauluma** Schs.

Separated from *Malupa* by shorter and broader forewings with a very oblique distal margin and a very round apex and interior angle. Two thirds of the antennae of the ♂ are pectinated, the pectinations distinctly white-haired inwards, palpi short, erect.

Type of genus: *P. nubila* Schs.

nubila. **P. nubila** Schs. (148 g). Forewing reddish yellowish-white, inner margin and apical third of costal margin violettish-brown, lighter brown dusting extends from the base through the cell to below the apex; a curved dark brown transverse line is at the base and is continued in a stripe from the costal margin below the median vein; a similar nebulous stripe is above the anal angle. Hindwing white with a brown marginal line and a small spot at the anal angle. Brazil (Castro, Paraná).

P. minna Schs. is darker than *nubila*, light brown, striped-reddish-brown at the costal margin, with *minna*. a fine dark marginal line shaded reddish inside and, subapically before it, with 2 black internerval streaks in darker shading; a dark brown shadow extends below the cell to the centre of the margin, a shorter one above it from the base to the cell-end; traces of a darker dentate postmedian line behind it. Hindwing white, brownish at the inner and costal margins, with a dark brown marginal line, darker at the interior angle. Expanse of wings: 30 mm. Brazil (Castro, Paraná).

62. Genus: **Drugera** Schs.

Antennae of ♂ tuftedly ciliated, the erect palpi with a long middle joint and a short terminal joint; the extraordinarily hairy legs are clad with hair-tufts on the middle and hind tibiae. Forewing broad with a rounded distal margin, neuration the same as in *Pauluma*, but the uppermost radial branch arises from the centre of the areole, the lowest subcostal branch without a stalk from the end of the areole.

Type of genus: *D. morona* Drc.

D. morona Drc. (148 g). Forewing light greyish-brown, with a broad dark brown subbasal transverse *morona*. band, two postmedian rows of indistinct vein-dots, a series of small light spots before the interior row. Hindwing light brown, darker at the margin. Costa Rica and Panama.

D. mimica Drc. is allied with *morona* and has also light greyish-brown forewings, dark brown basally *mimica*. at the costal margin, striped black in the basal area; a postmedian transverse band of white lunulae bordered with black, and a row of black dots before the black marginal line. Hindwing dark reddish-brown, fringe lighter. Expanse of wings: 48 mm. Colombia.

D. pallidiflava Roths. (148 g) is exactly like a *Meragisa* in its exterior; forewing lustrous light reddish- *pallidiflava*. yellow, olive brown at the base, two olive brown transverse bands, the interior one very oblique, the exterior one distally concave extending from near the apex into the anal angle; it shades distally an indistinct double dentate postmedian line; marginal line interrupted red-brown. Hindwing light reddish-brown. Expanse of wings: 49 mm. South-Eastern Peru.

63. Genus: **Eucerura** Schs.

Antennae pectinated to the tips, with short broad forewings with a very small areole from the centre of which the uppermost radial branch arises, the middle one from the centre of the cross-vein; the other veins as in *Pauluma*, except the costal branch of the hindwing, which arises only shortly before the cell-end. Only 1 species:

Type of genus: *E. pica* Btlr.

E. pica Btlr. has purely white forewings with black thick markings almost like those of certain species *pica*. of *Eucereum*; the two transverse lines are broken up into irregular thick black spots before which there are yet 2 large black triangular spots basally; the median area between the lines is more purely white and without spots; instead of the undulate line there are again 3 large black, more or less triangular spots. Hindwing blackish-grey, fringe speckled black and white. Expanse of wings: 50 mm. Brazil.

64. Genus: **Salluca** Schs.

Chiefly distinguished from the preceding genus by the much longer areole; the uppermost radial branch of the forewing arises a little before the centre of the areole; the middle joint of the palpus is long and hairy, the terminal joint smoothly scaled, short. Several pretty, mostly green species.

Type of the genus: *S. moruma* Schs.

S. moruma Schs. (148 h) is moss-green, shaded with brown at the base of the inner margin, with double *moruma*. black transverse lines filled with reddish-brown, and black subterminal spots bordered with brown, the largest being above the upper median branch; the cell-end streak is also bordered with brown. Hindwing dark grey, brownish at the base and inner margin. Mexico.

S. herbida Mschlr. (= *möschleri* Schs.) almost recalls *H. biundata*; forewing olive green, the two trans- *herbida*. verse lines broken up into small red-brown spots centred yellowish; a large yellowish reniform macula centred with red-brown is at the cell-end; the undulate line is yellowish, notched and accompanied inside by a faint red-brown shadow; fringe speckled yellowish and red-brown. Hindwing brownish-grey, fringe speckled yellowish. Expanse of wings: 45 mm. Guiana.

- psittica*. **S. psittica** Schs. is allied to *herbida*, forewing bright grass-green, the double transverse lines dark green, strewn with black at the costal margin, the posterior line treble, with a broad dark green shadow behind it, distally bordered with light green; distal margin darker green with a still darker interrupted marginal line. Hindwing light brown, distally dusted with grey. Expanse of wings: 44 mm. French Guiana.
- psitticula*. **S. psitticula** Dogn. is a small image of *psittica* with bright grass-green forewings and darker moss-green transverse lines, but of a much smaller size; palpi and ventral side pinkish yellowish, light brown in *psittica*; transverse lines broad, faded, partly bordered with light green, the cell-end streak light green. Hindwing yellowish pink, distally brownish, partly dusted with green. Expanse of wings: 35 mm. French Guiana.
- ruptilinea*. **S. ruptilinea** Schs. is still smaller than *psitticula*, forewing green, the double transverse lines broken up into single brown spots, the spots in the cell being largest, small below it, partly connected to indistinct lines; an irregular brown postcellular shadow, divided by the green veins; a dark brown shadowy stripe is before the whitish undulate line. Hindwing dull greyish-brown. Expanse of wings: 32 mm. Costa Rica.
- virens*. **S. virens** Dogn. is the smallest species, expanse of wings only 29 mm. Forewing of a delicate light green colour, the black transverse lines single, broken up into internerval dots, the posterior one bordered with white inside. Hindwing yellowish-grey. Expanse of wings: 29 mm. British Guiana.
- pistacina*. **S. pistacina** Schs. (= *maricolor* Kaye) has light green forewings with a white basal transverse line and a large brown costal-marginal spot; a violettish-brown shadow is below the median vein below and behind the cell-end, a reddish-brown spot in the cell is partly bordered with black; the irregular fine black postmedian line is double, the undulate line consists of reddish-brown spots bordered with black and white. Hindwing smoky brown, lighter towards the base. Honduras. Expanse of wings: 33 mm.
- amathynta*. **S. amathynta** Dyar (148 h). Forewing light grey, dusted olive green at the base of the costal margin and subapically, the double brown transverse lines very indistinct; the undulate line consists of brown spots bordered with yellowish outside, with white inside, as in *pistacina*. Hindwing light grey, darker at the margin, fringe white. Mexico (Vera Cruz, Misantla).
- gramina*. **S. gramina** Schs. (149 h). Forewing olive green, strewn with black, brown and white scales which being accumulated form indistinct double transverse lines, instead of the undulate line a series of dark internerval spots. Hindwing blackish-brown. Expanse of wings: 38 mm. Mexico (Orizaba).
- tarupa*. **S. tarupa** Schs. (149 h) has dark greenish-brown forewings with a large white area strewn with brown, between the cell and apex; before and behind the dark cell-end streak, which is bordered with brown inside, with white outside, there are double dark transverse lines, the posterior one filled with white; instead of the undulate line there are small irregular black shadowy spots. Hindwing smoky brown, whitish towards the base, with a greenish-brown spot before the whitish apex, bordered by two black lines. Expanse of wings: 33 mm. South-Eastern Brazil (São Paulo).
- schausi*. **S. schausi** Dogn. is a larger species, forewing yellowish ochreous with an olive tint, marginal part lighter, the median area strewn with olive from the costal margin to the lower cell-end, from there obliquely to the inner margin narrower, without any other markings than a submarginal row of brick-red internerval spots. Fringe slightly tinged with pink. Hindwing yellowish-white, broadly dusted with pink at the margin. Expanse of wings: 48 mm. Brazil (Joinville).
- podrida*. **S. podrida** Dogn. Forewing whitish-grey with irregularly dispersed rusty brown spots, and scantily strewn with yellow and black scales. Hindwing whitish, dusted with red-brown at the inner margin and distal margin. Expanse of wings: 40 mm. Ecuador.

65. Genus: **Skaphita** Schs.

Only two thirds of the antennae pectinated, the pectinations set with dense hair, the short palpi hairy with a small terminal joint. Anterior tibia with a large, almost circular hair-tuft. Forewing long and narrow with an oblique distal margin; neuration as in the preceding genera, with separately arising veins 3 and 4 on the small hindwing with a convex costal margin. Only one very widely distributed common species.

Type of genus: *S. salona* Drc.

- salona*. **S. salona** Drc. (148 h). Forewing bone-coloured, lightest below the median vein as far as the margin, violettish-grey and brown at the costal margin, strewn with olive brown scales at the inner margin, with double indistinct and interrupted transverse lines and black longitudinal stripes submedianly and at the inner margin, before the centre, behind it, above and below the lower median branch, and between the lower radial branches;

a thick submarginal black line projects twice distally; two fine black transverse lines on the lighter margin and an interrupted lunular line before them. Hindwing whitish, smoky at the margin. The type was described from Central America. Farther to the south the species occurs in a much darker and more variegated form: — *meridionalis* f. n. (148 h) with a distinctly carmine costal-marginal part dusted with violet, and a green inner-marginal area and distal margin. Thorax violettish-red, head and margins of tegulae green. Brazil. meridio-
nalis.

66. Genus: **Dicentria** Herr.-Schäff.

This genus contains a great number of species of an uncommonly typical and uniform exterior with long and narrow forewings, a very oblique and somewhat dentate distal margin, the neuration exactly as in the preceding genus, with a more or less distinct dent of scales at the inner margin. The ♂ antenna is pectinated only in the first half or two thirds, the ♀ antenna plain; palpus very short, hairy, with a tiny last joint, the head bears a slight tuft of hairs. The two sexes are very different.

Type of genus: *centralis* Herr.-Schäff.

D. centralis Herr.-Schäff. (148 i) has yellowish brownish-grey forewings, dusted with whitish-grey in *centralis*. the median area at the costal margin, with yellowish olive behind it in the cell, with fine indistinct transverse lines, the posterior one double, a slight brightening behind it in the subterminal area; the veins before the margin are fine black, dark streaks are between them towards the apex, that above the uppermost radial branch being the thickest, the apex above it whitish-grey, obliquely cut off inwards; a thick black oval spot at the cell-end. Hindwing whitish with a brownish inner margin, marginal line and veins. — f. *sabella* Drc. (148 i) is by *sabella*. far more common and without the black discal dot. The wide range extends from Mexico to Brazil.

D. arpi sp. n. (148 i) may be another form belonging to *sabella*; it is smaller, more slender and much *arpi*. lighter, with yellow and greenish scales in the whole costal-marginal area, darkened lilac brown at the inner margin, the whole median area light yellowish without markings, only an olive green subbasal line and an antemedian line being visible, the latter rectangular on the median vein; the discal streak is feeble, brownish, the postmedian vein-streaks parted by light are scarcely prominent, only the subapical black internerval streaks and the whitish-grey apical blotch are distinct. Hindwing somewhat darker than in *sabella* and broader brownish at the inner margin. Brazil (Joinville), received from Mr. ARP. Types in the Museum SENCKENBERG, Frankfurt on the Main.

D. quirosia Schs. is very near to *centralis*, smaller, lighter, of a somewhat more reddish tint, dusted with *quirosia*. brown only at the base of the costal margin, with a dark grey stripe in the base of the cell, the velvety black discal dot smaller, two dark brown internerval stripes behind it extend to the margin between the radial branches, the light oblique apical blotch is absent. Expanse of wings: 37 mm. Guatemala. — f. *praealta* Dogn. *praealta*. is a smaller southern race from the Amazons (São Paulo de Olivença), forewing of a light brown colour, yellowish at the costal margin, still lighter in the distal half; a brown internerval stripe between veins 4 and 5 does not extend to the margin. Expanse of wings: 30 mm.

D. linita Schs. Forewing reddish-brown, dusted with lilac at the costal margin, broadly greenish- *linita*. yellow at the inner margin and grey at the distal margin, strewn with olive; markings as in the preceding species, but the olive transverse lines more distinctly double, with a fine brown basal ray below the median vein at the base, and a brown inner-marginal spot below it; at the cell-end there is a velvety black crescentiform streak from the centre of which a fine black short streak extends distally, a brightening behind it as far as the postmedian line; dark internerval streaks at the apex and inner angle. Hindwing grey, yellowish towards the base and at the inner margin, with a dark anal spot. The larger ♀ is greyer, veins strewn black and white, with much less distinct transverse markings. Expanse of wings: ♂ 37, ♀ 43 mm. Mexico (Jalapa).

D. muelleri sp. n. (148 k) has ash-grey forewings with a slight lilac tint, a fine black basal ray as far as *muelleri*. the centre of the median vein, and a velvety black distinct fine crescentiform streak at the cell-end; the anterior transverse line is hardly traceable, the posterior one double, sharply dentate, its distal part behind the cell red-brown; the apical part of the wing from the postmedian line down to vein 3 is light yellowish-white, the subterminal portion behind the cell particularly light, a red-brown longitudinal stripe in it extends above and below the median radial branch to the margin; the 3 radial branches are distinct and fine black behind the discal crescent as far as the postmedian line, a white wedge between the median branches is before the margin, broadly entering into the fringe and bordered with black behind; the light fringe is speckled red-brown on the ends of the veins. In another ♂ the light apical area of the type is entirely dusted with grey like the rest of the wing, and small dark subterminal internerval spots are noticeable here, whereby this specimen approaches the ♀ which looks like the ♀ of *linita* and is quite purple grey, with a red-brown tint towards the inner margin, the double postmedian line very feebly marked red-brown, dusted with whitish-grey at the apex and the distal ends of the subterminal streaks; fringe red-brown, the white subanal streak is absent. Hindwing white, with a slight yellowish tinge, a grey anal spot continued for a short distance as a marginal line, smoky in the ♀ at the

costal margin, apex, and distal margin. Thorax violettish-grey, the collar with intermixed greenish hairs, *cinescens*, abdomen yellowish-grey. Mexico City. — *cinescens* f. n. is the greyer form, from Zacualpan, in February and March. Types ♂♀ in the Coll. DRAUDT.

cerriben. **D. cerriben** Dyar (148 k) is bluish ash-grey, slightly dusted at the inner-marginal area, with a black basal ray and a black dot in the lower cell-angle, surrounded by brownish-grey dusting; the anterior transverse line is entirely absent, the posterior one is very oblique at the costal margin and then marked doubly at the inner margin, quadrupled here by black strigiform spots before and behind it, a white subanal streak edged with black inside is above it; subapical black streaks are at the costal margin, small less distinct internerval spots below them seem to be removed a little farther towards the margin. Hindwing white with a black inner-angular spot. Mexico (Zacualpan).

indepta. **D. indepta** sp. n. (148 k) is allied to *cerriben*, but much larger and darker grey, besides the basal streak also the median vein is finely black, and the discal dot is not in the lower cell-angle, but close below the origin of vein 5; the posterior transverse line is distinct and double not only at the costal and inner margins, but in its whole course, filled with light, and behind it, above and below the median radial branch, a blackish-brown stripe extends to the margin; the white subanal spot is broader and whiter. The white hindwing is broadly smoked at the costal margin. Mexico (Zacualpan, in September); type: ♂ in the Coll. DRAUDT.

vallima. **D. vallima** Schs. (148 k) has light brownish forewings dusted with greenish and reddish at the costal margin, the veins in the distal part strewn with black and white, the beginnings of the transverse lines at the costal margin marked by darker spots, besides only the double posterior line marked behind the cell; a greenish spot mixed with lilac before the dark cell-end streak is situate in the cell; the distal margin is broad darker brown, with dark velvety brown internerval streaks subapically and above the anal angle, the latter streak followed by a white streak; the light brown fringe is speckled darker on the ends of the veins. Hindwing diaphanous violettish-brown, dusted darker brown at the margin. French Guiana. Expanse of wings: ♂ 36, ♀ 42 mm.

patula. **D. patula** Schs. is somewhat like *muelleri*, but considerably larger, forewing violettish-grey in the basal half and along the submedian vein to the margin, light brownish olive below the cell and apically, with a dark brown basal ray and discal streak, shaded with brown behind the latter; a fine interrupted brown postmedian line is in a broad reddish-yellow shadowy stripe which extends from the costal margin to the lower median branch; vein 5 is broadly bordered with dark brown on both sides as far as the margin, a brown subanal spot encloses a light wedge. Hindwing white, brownish at the inner margin and the veins. Expanse of wings: 41 mm. Costa Rica.

obligata. **D. obligata** Dyar (149 a) is also similar to *muelleri* and as large as *patula*. Forewing grey, densely dusted with black in the basal two thirds, the cell-end streak in an oval light spot, with a brown internerval streak behind it between the veins 4 and 5; the light postmedian line is almost straight; apex light grey; the veins are striped black towards the margin and thickened on the fringe. Hindwing white with darker veins, narrowly grey at the costal and distal margins, with a blackish anal-angular spot. Mexico (Zacualpan).

marimba. **D. marimba** Schs. has brownish-grey forewings, darker at the base of the costal margin and in the cell, the veins strewn with black and white, with a light olive tint in the distal half of the cell and below it, fine double darker transverse lines, the posterior one dentate, the distal portion punctiform in the lower half; a brown, white-edged line is at the cross-vein, a dark brown stripe behind it extends to the postmedian line between the veins 4 and 5; small dark spots in the darkened distal-marginal part are behind a marked undulate line, white dots above and below vein 2 at the anal angle. Hindwing scantily scaled, white, with darker veins and marginal line, as well as a dark inner-angular spot and a chalky white spot above it. The ♀ shows the small dark marginal spots distally bordered with light, and a smoky margin of the hindwing. Expanse of wings: 36 mm. Guatemala, Costa Rica.

limosa. **D. limosa** Schs. Forewing blackish, strewn with light grey along the costal margin and at the apex, the transverse lines entirely covered by the ground-colour, only the undulate line is somewhat more distinct; a short black postcellular longitudinal streak. Hindwing white, smoked at the margins, a large blackish spot at the anal angle. Expanse of wings: 48 mm. A large species, described from a single ♀, from Rio de Janeiro.

limosoides. **D. limosoides** Schs. (= *claricostata* Dogn.) (149 a) is very similar to *limosa*, forewing dark brown, apex and cell lighter, dusted with yellowish and olive green, with a large olive green spot bordered with white at the cell-end; the double dentate indistinct posterior transverse line is partly broken up into vein-dots, small oblong dark subterminal spots are edged with white outside at the costal margin and anal angle, the ends of the veins speckled black. Hindwing white with brownish veins and marginal line, as well as an apical and anal-angular spot. Expanse of wings: 39 mm. Costa Rica, French Guiana.

fechima. **D. fechima** Schs. is allied to *limosoides* from which it differs in the more red-brown colour, head and thorax being cinnamon and chestnut brown, abdomen brown, the base and the last two segments reddish cinnamon. Forewing cinnamon brown in the basal and inner-marginal areas, black above it as far as the post-

median line, the costal area light reddish-yellow, broader at the apex; a cinnamon brown streak at the cross-vein; a blackish postmedian transverse shadow, bordered with cinnamon brown outside between 2 and 6, whitish scales on the veins here; marginal area brown, with small dark subterminal spots below the costal margin; fringe reddish yellow, speckled dark on the veins. Hindwing white, strewn with reddish cinnamon on the marginal veins as well as at the margin. Anal angle scaled dark. Expanse of wings: 37 mm. Brazil (Rio Purus).

D. ravana Dogn. has light yellowish reddish-brown forewings the disc broadly darkened blackish-brown, *ravana*. concave between the veins 4 and 6, a dent above them reaches the costal margin before the apex; besides only brown internerval lunules are visible, the lowest being thickened; the centre of the inner margin is slightly strewn with black scales. Hindwing dirty white, smoked at the margin. The ♀ has a less dark disc, more brownish margins, and greyer hindwings. Expanse of wings: 38 mm. San Salvador.

D. dela Drc. (149 a) is a large beautiful species the scheme of marking of which is similar to the following *dela*. large group. Forewing light brownish-yellow, brown at the costal margin, in the anal half of the inner margin and in a broad stripe between and above the veins 4 and 5, dusted with white and grey at the costal margin before and in the middle, feebly brownish in the cell and below it, with a brown basal ray. Hindwing yellowish-white, a black wedge-shaped spot at the anal angle. The ♀ shows a double dentate postmedian line, and the whole anterior part of the wing as far as the latter is blackish-grey, suffused more with red-brown towards the inner margin. Hindwing feebly smoked; thorax in both sexes intensely scaled whitish-grey. Mexico.

D. psamathe Schs. (149 a) is smaller, with an almost quadrangular dark brown spot at the base of the *psamathe*. costal margin and of the cell, a black spot in the cell-end before the brown discal streak which is surrounded with white; the brown anal-angular spot is removed higher between and above the median branches, and contains a small light wedge-shaped spot; the veins of the marginal area are blackened as far as into the fringe. Hindwing yellowish-white with a blackish anal spot which is obliquely traversed by white. Brazil.

D. lerma Schs. is allied to *psamathe*, forewing darker brownish-grey, the base narrowly blackish-brown *lerma*. with a fine basal ray below it; a fine black stripe in the cell is widened at the cross-vein and extends as a thick black line along vein 5 to the margin; the median area is shaded dark at the inner margin, the distal half of the costal margin is yellowish-white; white longitudinal stripes above and below the black radial stripe do not quite reach to the margin, dark longitudinal stripes are above the upper one and below the lower one. Hindwing as in *psamathe*. Expanse of wings: 38 mm. Guatemala.

D. rivalis Schs. (149 a) looks also like *psamathe*. Forewing light reddish-brown, shaded with red-brown *rivalis*. at the inner margin, with a dark brown spot at the cellular and costal bases; cross-vein as in *psamathe*, a darker shadow before it is continued after an interruption through the cross-vein to the margin; a postmedian transverse row of dark vein-streaks and dark subterminal spots behind them towards the apex, a brown oblique spot above the anal angle. The ♀ is greyer with more distinct dentate transverse lines, hindwing brownish at the distal margin, in the ♂ as in *psamathe*. Costa Rica.

D. palmita Schs. is allied with *rivalis*; the whole basal third of the cell on the forewing and the costal *palmita*. margin above it are blackish-brown, the cell behind it white, an oval dark red-brown spot before the light brown cross-vein, behind it a dentate blackish shadow; the whole postmedian area above vein 3 is light lilac brown, the distal and inner margins somewhat darker lilac brown; 2 submarginal rows of dark vein-streaks. Hindwing as in the preceding species. Expanse of wings: 40 mm. British Guiana.

D. stridula Schs. has reddish-brown forewings, dusted with lilac above the inner margin, in the cell and *stridula*. above the upper median branch; a dark brown stripe extends from the base of the costal margin through the cell and between the veins 2 and 3 to the margin, a similar stripe from the brown cross-vein to the margin, a shorter stripe above it, a greenish-grey spot in the cell-end; double dentate transverse lines are filled with somewhat lilac; a short velvety brown subapical strigiform spot, a white dentate subanal spot. Hindwing smoky brown. Expanse of wings: 37 mm. French Guiana.

D. missilis Schs. is near *stridula*, but smaller; forewing light brown, with a reddish tint in and below *missilis*. the cell and in the centre of the distal margin, with a velvety blackish-brown cross-vein streak and a stripe to the margin behind it; the cellular veins are fine dark brown towards the margin, vein 5 is broader and more olive brown; a dark basal ray extends to the anterior transverse line forming 3 bows; the dark brown subanal spot, as in the preceding species, between the median branches with a dentate white spot in it, the base of the 3 lower cellular branches is also shaded dark. Hindwing white with the usual dark inner-angular wedge. Expanse of wings: 31 mm. Costa Rica.

D. disparilis Schs. (149 b) is a small species with a scheme of markings very similar to that of *missilis*; *disparilis*. forewing very light yellowish-brown, somewhat darker in the inner-marginal half; the space between the basal ray and the median vein is filled with dark brown; double, strongly dentate transverse lines are distinct, the

posterior one followed by double rows of dots on the veins. Hindwing white, the veins finely brownish towards the margin, the inner angular spot indistinct or absent. The ♀ forewing is quite dark red-brown, without any longitudinal stripes, only the subapical black wedge is very distinct, the transverse lines more or less broken up into rows of dots; ♀ hindwing blackish-grey. Mexico.

moribunda.

D. moribunda Dyar (149 b) is extremely similar to *disparilis*, but larger and with broader wings, the black cell-end dot is entirely enclosed in the light cellular stripe, whilst in *disparilis* it coincides distally with the dark radial ray, the transverse lines are much less distinct, only the lower part of the distal one is more distinct. The anal-angular spot of the hindwing is larger and grey. Mexico (Zacualpan), taken in July.

phthimena.

D. phthimena Dyar is very similar to *moribunda* and is from the same habitat, but the forewings seem to be a little narrower, the space between the basal ray and the median vein is not dark, the white subanal spot is linear and more oblique; at once discernible by its brownish-grey hindwings which are only whitish in the disc. Expanse of wings: 38 mm.

trifasciata.

D. trifasciata Dogn. has light reddish yellowish-brown forewings with a slight pink tinge, dusted with moss-green at the costal margin, brown at the base, with 3 straight blackish-brown longitudinal stripes, a subcostal one, a median one as in *disparilis*, and a third below the median one which extends then indistinctly between the veins 2 and 4 into the margin; the lower half of the cell is strewn with white, the cross-vein moss-green and white. Hindwing purely white, feebly brownish at the anal angle. Expanse of wings: 36 mm. Argentina.

unifasciata.

D. unifasciata Dogn. (149 b) is coloured like *trifasciata*, but it has only the median longitudinal stripe through the cell and terminating obliquely between the veins 5 and 6 at the margin, blackish scaling below it at the margin between the lower median and radial branches; 3 fine dark antemedian transverse lines are indicated. The brown anal spot on the purely white hindwing is longer and extends at the inner margin upwards. Expanse of wings: 36 mm. Colombia (Muzo).

clarita.

D. clarita Schs. (149 b) forms the transition to the next group of better known species which are also represented in North America. The shape of the wings is somewhat more elongate, narrower; the ground-colour is the same as in the preceding species, the cell remains light, the discal longitudinal blotch begins only at the cross-vein, it is indistinct and narrows down towards the margin where it is bordered by fine dark brown veins on both sides; a black fine basal ray is present as well as a narrow oblique blackish diffuse spot above the anal angle and two fine grey longitudinal stripes above vein 6 as far as the margin; the costal margin is traversed by very oblique beginnings of dark transverse lines. Hindwing yellowish-white, spotted brown at the anal angle. Expanse of wings: 47 mm. Brazil.

drucei.

D. drucei Schs. (= *laciniosa* Drc. nec Edw.) (149 b) is a common and widely distributed species, with light reddish yellowish-brown forewings, mostly more intensely strewn with purple brown at the inner margin; the cell remains light, a fine olive brown basal ray is below it, a black cross-vein streak in the darker olive brown cell-end, before this streak fragments of a double black and brown median line; instead of the longitudinal stripe between the veins 4 and 5 there are only 2 fine feeble olive grey longitudinal shadows which are very inconspicuous, a white wedge-shaped spot is behind the black anal oblique spot. Hindwing diaphanous yellowish-white, brownish at the costal and inner margins, with a brown anal-angular spot. The very dissimilar ♀ shows a yellowish-brown ground-colour dusted with dark purple brown in the basal half except the inner margin and in the marginal quarter, as well as subterminally between the veins with 2 longitudinal streaks each. Hindwing light greyish-brown with light fringe. Mexico. — The larva was found by my father in March on roses, according to the sketch it was of the same shape as the well-known larva of *D. lignicolor* with the anteriorly bent cone on the 4th segment, but besides with 4 smaller protuberances on the next segments and a point on the 11th segment. The colour of the body is ochreous, densely and irregularly spotted black as on the porcelain-white head, the protuberances, legs and abdominal legs rosy red. They went into the earth for the pupation and yielded the imago in April.

minotelis.

D. minotelis Dyar (149 e) is closely allied to *drucei* and the female only differs in the somewhat broader wings and more greyish-brown, not so red colour, being somewhat lighter whitish subapically, so that the black wedge between the lowest subcostal branches and the triangular dark brown costal-marginal spot above it are more prominent, the anal angle being darker, too. The ♂ has also somewhat shorter wings and is smaller than *drucei*, with almost the same markings, the inner-marginal part not darkened at all, the costal margin dusted with red-brown; the discal streak which is only present in the lower half of the cross-vein in *drucei* is extended here as a long, distally concave fine streak along the whole lower border of the areole, in front of it the cell is somewhat lighter, behind it there is olive grey dusting; fringe along the distal half of the inner margin and at the anal angle deep purple brown. The types of this species fly in Mexico in the surroundings of the City.

fumata.

— A larger and much darker race from Zacualpan is: — **fumata** f. n. (149 c) in which the costal margin is deeper red-brown, the subcosta below it dusted with iron black as far as the apex, a large blackish-brown spot behind the cross-vein, below this spot the anal half of the inner margin is extensively darkened olive grey, the double transverse lines are more distinct and darker red-brown, the hindwing feebly smoked.

D. hidalgonis *Schs.* is likewise very closely allied to *drucei*, but with broader wings and darker at the *hidalgonis*. costal margin, the basal half of the forewing dusted with light brown, the subcostal area shaded with lilac grey, the two lower radial branches striped brown. Expanse of wings: 44 mm. Mexico (Hidalgo).

D. fera *Dogn.* is also very similar to *drucei*, the wings are somewhat less long, the abdomen shorter, the *fera*. uppermost radial branch of the hindwing on a much longer stalk with the subcostal branch. The forewing is coloured as in *drucei*, the basal part of the costal margin, the cell and below it the area at the base of its lower branches dusted with lilac, the space between the median vein, the lower median branch and the inner margin shaded with olive, the inner-marginal vein lilac; two white small spots above each other at the anal angle, and two more in the upper half of the wing above a long brown stripe along vein 5; subapical white dusting, an olive grey spot behind the black cross-vein streak. Hindwing as in *drucei*. Expanse of wings: 43 mm. South Eastern Peru.

D. violascens *Herr.-Schäff.* (= *laciniosa* *Edw.*, *brunnipennis* *Raye*, *phraortes* *Drc.*) (149 c) is a smaller *violascens*. light edition of *drucei*, still smaller and with narrower wings than the likewise very similar *minotelis*; the costal margin of the light yellowish-brown forewing is darker red-brown than in *drucei*, the inner-marginal part not darkened, all the transverse markings lighter and finer, the area between the basal ray and the median vein darkened olive grey, the stripe behind the cross-vein below vein 5 more distinct, olive grey, narrower towards the margin. The ♀ is also somewhat like that of *drucei*, it is more unicoloured red-brown, not lighter yellowish-brown at the inner margin and subterminally, hindwing somewhat lighter. Mexico.

D. simplex *Dogn.* is allied to *violascens*, but the shape of the wings is somewhat broader, the inner angle *simplex*. less obtuse, the distal margin scarcely dentate, the short abdomen hardly projects beyond the hindwing. The costal margin is blackish, not red-brown, a blackish shading is below and behind the cell, a light longitudinal stripe is between the veins 5 and 6, 2 small black spots at the anal angle. Hindwing as in the preceding species. Expanse of wings: 29 mm. Paraguay.

D. rustica *Schs.* (149 c) is considerably darker than the preceding species, the forewing is brown, strewn *rustica*. with blackish at the base, at the inner margin and a part above the anal angle and at the cell-end, with dark postmedian internerval streaks and black vein-dots; the anterior transverse line is very indistinct; dark sub-terminal internerval spots, the spot above the anal angle being bordered with reddish-yellow. Hindwing white, strewn with blackish-brown at the margin, with a dark inner-marginal streak and anal-angular spot. The ♀ is much darker with quite obsolete markings and dark hindwings. Costa Rica.

D. tacita *Schs.* is much smaller, the brown forewing is strewn with brownish-black at the base, below *tacita*. the cell and vein 2, and at the margin between veins 2 and 4, without any other marking but some subapical black marginal spots. Hindwing white with dark inner-marginal shading. Expanse of wings: 34 mm. Costa Rica.

D. lignicolor *Wkr.* (= *virgata* *Pack.*, *lignigera* *Wkr.*) (149 c) has light ash-grey forewings longitudinally *lignicolor*. striped brownish between the veins, with 2 more distinct subapical strigiform spots between which whitish stripes extend, tinted ochreous below the median vein; a brown discal dot in the lower cell-end, a brown longitudinal streak behind it extends to the margin; a dark basal ray is submedian, the inner margin is strewn with darker grey, the transverse lines are absent. Hindwing white. — The larva is green with single small brown dorsal spots and a large brown saddle-spot on the middle segments, obliquely continued downwards as far as the claspers; a twopointed cone bent forward is on the 4th segment, and a pointed elevation on the last segment. It lives on oaks, beeches and birches. The range extends over the whole Atlantic States. — f. **delicta** *Dyar* *delicta*. is a somewhat smaller form, of a more delicate ash-grey colour, not striped brownish between the veins, but the yellow tinge below the median vein more distinct. Florida.

D. coloradensis *Edw.* (149 d) is smaller and much lighter than *lignicolor*: greyish-white, silvery white *colora-* *densis*. at the costal margin, with a slight brownish tinge along the inner margin, and the same markings as *lignicolor*, dusted darker behind the cross-vein; hindwing white, a dark spot at the anal angle. Larva unknown. From Colorado and New Mexico.

D. pallida *Stkr.* is a still lighter species, but larger and with broader wings than *coloradensis*, monotonously *pallida*. yellowish-white, not lighter at the costal margin, but brownish at the inner margin; the brown discal dot in the lower cell-end is thicker and above it in the upper angle there is another one; the dark longitudinal streak to the margin is absent, a black basal ray is very conspicuous; anterior transverse line absent, instead of the posterior line there are traces of dark vein-dots; instead of the undulate line there is darker shading. Hindwing brownish-grey. Texas.

D. semirufescens *Wkr.* (= *eximia* *Grt.*) (149 d) is externally very similar to *Schizura concinna* but much *semi-* *rufescens*. larger; forewing brownish ash-grey, browner at the inner margin, with a long basal ray and discal dot in the lower cell-angle, behind which a dark longitudinal stripe extends to the margin; at the costal margin, especially in the apical half, very oblique double streaks, transverse lines absent altogether. Hindwing white with a large

dark inner-angular spot. Distributed in the Atlantic States. — Structure of larva like that of *lignicolor*, but with another elevation on the 9th segment; thoracal segment whitish, marbled reddish, the rest of the body brown with a velvety blackish-brown saddle-spot. It lives on many foliage-trees, chiefly on willows, poplars and birches, as well as on maple, apple and alder.

perangulata. **D. perangulata** *Edw.* (149 d) is somewhat like *semirufescens*, but more whitish ash-grey, with a reddish-brown tint at the inner margin; it is easily discernible from all the preceding species by the distinct strongly dentate double postmedian line and a dark shadowy spot behind the cross-vein; dark streaks in the marginal area between the veins, the two thickest above the anal angle, some finer ones subapical. Hindwing dirty whitish with a blackish inner-angular spot. Colorado, Utah.

mami. **D. mami** *Schs.* (149 d) is blackish-brown on the forewing as far as the black anterior transverse line, silvery grey between the dusted cinnamon brown median vein and the similarly coloured inner margin; the median line is divided into two branches below the cell, the cell-end behind it is whitish, behind the velvety black cross-vein streak follows a broad blackish-brown transverse shadow reaching neither the costal nor inner margin, then the double black deeply dentate posterior transverse line which is filled with lighter; some ochreous scales behind it; the whole apical half is light grey, the marginal area below it red-brown with fine black internerval streaks and a quadrangular white spot above the anal angle. Hindwing whitish, broadly brownish at the margin. Expanse of wings: 34 mm. Bolivia.

hertha. **D. hertha** *Dogn.* is very different; forewing reddish light brown, strewn with whitish in the upper half, an indistinct ring-macula and reniform macula in the cell; the anterior transverse line is indistinct, the posterior one is quite absent, some brown internerval streaks before the margin. Hindwing white, broadly smoked at the costal margin and distal margin. Expanse of wings: 40 mm. Described from Argentina.

klagesi. **D. klagesi** *Drc.* has remained unknown to me, it seems to belong near to *centralis*. Forewing light reddish light brown, strewn with brown scales, greyish-black in the basal area; a large black spot at the cell-end. Hindwing white, grey at the costal margin and apex, a black spot at the anal angle. Expanse of wings: 45 mm. Trinidad.

67. Genus: **Schizura** *Dbld.*

It shows in general the very same anatomical marks as *Dicentria* and is distinguished from it merely by the shorter and broader shape of the wings and the shorter stouter abdomen. Yet the transition from the narrow-winged forms to the broad-winged ones is so gradual that several species may be ranged under either of the two genera ad lib. Beside a number of North American species, also some tropical forms have been described to belong to this genus.

Type of genus: *S. impomeae* *Dbld.*

impomeae. **S. impomeae** *Dbld.* (= *biguttatus* *Pack.*, *confusa* *Wkr.*, *ducens* *Wkr.*, *corticea* *Wkr.*, *compta* *Wkr.*, *nigrosignata* *Wkr.*) (149 d) is a larger species with reddish-brown, black-veined forewings with a grey costal margin with the brown beginnings of the transverse lines the anterior one of which is the most distinct; the cross-vein streak is red-brown, surrounded by grey, and shaded dark distally and below; the veins are interrupted by grey postmedianly, two submarginal rows of indistinct red-brown internerval spots; the red-brown fringe is speckled dirty white. — f. **cinereo** *frons* *Pack.* (= *urtipennis* *Wkr.*) (149 d) exhibits the whole discal part of the forewing from the base to the margin dusted with dark brown, costal and inner margins ash-grey with a lilac tint. — f. **telifer** *Grt.* is founded upon aberratively marked specimens with 2 long black longitudinal stripes, one through the cross-vein streak, the other one along the submedian vein. — The larva is green on the 3 thoracal segments, dark brown on the head and the posterior segments with 2 coherent white dorsal spots marbled brown on the middle segments and a posteriorly open similar V-spot behind the two-pointed dorsal protuberance on the 8th segment; the point on the 4th segment is bent hindward, not forward as in *Dicentria*, and erectile and movable as there. It lives in the Northern States on oaks and many other foliage-trees such as maple, elms, birches, besides on *Rubus*, *Vaccinium*, *Ceanothus* and other plants; in the Gulf States it is found on *Ipomea coccinea*. It transforms in a web in the earth, and the imago appears during a very extensive period from March until August, probably in several generations.

concinna. **S. concinna** *Abb. & Sm.* (= *nitida* *Pack.*, *deba* *Drc.*) (149 c) is much smaller with light brownish forewings, the inner-marginal area tinged red-brown, a small discal dot below the origin of vein 5 and some dark strigiform spots submarginally at the anal angle and subapically; the costal-marginal area is tinged somewhat more lilac grey. Hindwing white, slightly smoked at the margin. The ♀ is darker on the whole with brownish-grey hindwings. — f. **salicis** *Edw.* (= *riversii* *Behr*) from California hardly deserves a denomination, it is only somewhat larger with somewhat more pointed hindwings. The larvae have habits quite uncommon

for a Notodontid larva, remaining gregariously together until the pupation. It is red-brown with very many black longitudinal lines which, from the 5th to 10th segments, are situated subdorsally in a broad white stripe. Head and 4th segment with an incassation and the short protuberance are coralline; the tubercles bear stiff black bristles. It lives on numerous foliage-trees and many low plants and has two breeds a year. From Maine and Canada to Missouri and to the south as far as Texas, Georgia and Florida, finally in Mexico.

S. tomaea Dyar (149 e) is similar, somewhat larger, of brighter colours, broadly whitish-grey in the *tomaea*. costal area, yellowish in the centre, red-brown at the inner margin, the transverse lines better visible, a short longitudinal streak behind the black discal dot, and a fine basal ray; thicker black oblique streaks above the anal angle, and a white one behind them. Hindwing whitish with a broad smoky margin and a darker anal spot. Mexico (Zacualpan).

S. pegasis Schs. Forewing brownish, reddish-yellow at the costal margin, broadly dusted with *pegasis*. violettish-brown at the inner margin, the yellowish-reddish basal area defined by a black transverse line, a brown longitudinal stripe behind the short brown discal streak; the dentate transverse lines are indistinct; a submarginal row of small dark spots, fringe speckled brown and yellowish. Hindwing brown with yellowish fringe. Expanse of wings: 40 mm. Brazil (Petropolis).

S. dospeppa Dyar has reddish-grey forewings shaded blackish basally, with a lighter transverse line *dospeppa*. bordered with black, which is only distinct in the inner-marginal half; the white undulate line edged with black is distinct and forms a white spot above the inner angle, crossed by 2 black streaks. Hindwing yellowish-white with a dark anal spot traversed by white. Expanse of wings: 33 mm. Mexico (Guerrero).

S. nocens Dogn. is somewhat similar, greyish-brown, darker at the base, with darker brown longitudinal *nocens*. stripes in all the cellular spaces except the apical region, with a red-brown spot in the lower half of the cross-vein, and a curved lighter transverse stripe behind it; the whitish fringe is speckled brown on the ends of the veins; hindwing whitish, brownish in the marginal half, with a brown anal spot. Expanse of wings: 39 mm. San Salvador.

S. manca Schs. is a smaller brown species, shaded with grey in the costal half as far as behind the cell, *manca*. with indistinct transverse lines, the anterior one double, and with a fine velvety brown cross-vein streak and a brown postmedian shadow behind it, which becomes more distinct towards the inner margin; brown longitudinal stripes extend between the radial branches to the margin, dark internerval lines before the margin, a white spot above the anal angle: Hindwing whitish with a broadly smoked margin. Expanse of wings: 33 mm. Costa Rica.

S. schausia Jones. Forewing lilac brown, dusted with dark grey, with double transverse lines filled *schausia*. lighter, almost with white at the costal and inner margins, and a dark median shadow; the distal half of the costal margin is black, striped and spotted white; the anal half of the distal margin is black, bordered with white inside, fringe speckled black and white, in the upper half with the fringe brown. Hindwing white, red-brown at the margin, with a black and white anal spot. Expanse of wings: ♂ 40, ♀ 42 mm. Brazil (Paraná).

S. salvador Schs. Head and thorax white mixed with brownish fawn; abdomen brownish cinnamon, *salvador*. whitish beneath. Forewing brown, with black veins and a black basal streak below the cell, a round black spot below the cell between 2 and 3; brown postcellular internerval streaks, the white fringe speckled dark. Hindwing white, veins and margin brown with bronze gloss, darker at the anal angle. Expanse of wings: 40 mm. San Salvador.

S. tizoc Schs. (149 e). Forewing violettish-grey, darkened at the base, with velvety brown longitudinal *tizoc*. stripes in the marginal half, which are accompanied in the centre of the margin by white ones; base of submedian vein also whitish. Hindwing white, spotted dark brown at the anal angle, fringe speckled brown. Peru.

S. badia Pack. (= *significata* Wkr.) (149 e). Forewing red-brown, strewn with ash-grey and darker brown, *badia*. dusted with grey before the black cell-end streak, behind it two black radial rays to the margin; the apex and stripes between the black veins are white. Hindwing white, smoky in the marginal half. — The larva is green with a purple brown longitudinal stripe on the dorsum of the first 4 segments, yellow irregular dorsal figures behind it, and a more or less complete brown belt around the 6th segment. It lives on *Viburnum lentago* and develops in August. Atlantic States.

S. unicornis Abb. & Sm. (= *edmandsi* Pack., *humilis* Wkr.) (149 e) has ash-grey forewings mixed with *unicornis*. whitish, red-brown and yellowish-green, the base of a purer whitish colour, bordered by a black line which is preceded inside by a brown parallel line; the antemedian area before the double dentate anterior transverse line is darker, the median area before the black discal streak is whitish, a series of red-brown spots behind the straight dentate black postmedian line; costal margin and apex whitish, with short black longitudinal streaks subapical and above the anal angle, spotted white behind the latter streaks. Hindwing dirty whitish with a broad faded white postmedian band and a blackish anal spot, in the ♀ brownish-grey. — The larva is green on the thoracal segments, brownish-yellow behind them, with darker brown oblique streaks directed posteriorly

downward, and a posteriorly open dark brown V-mark edged with white on the 8th to 10th segments; the first 3 segments exhibit a broad purple brown dorsal stripe. Moreover it is rather variable and lives on nearly all sorts of foliage trees, chiefly on species of *Pirus* and *Prunus*. — f. **conspecta** *Edw.*, the race from California, is larger, lighter, with a purer white median area and purer white hindwings. The type is distributed over nearly the whole of the United States and Canada, and common.

errucata. **S. errucata** *Dyar* is very similar to *unicornis*, smaller, without the red-brown tint in the postmedian area and with purely white hindwings which are also in the ♀ whiter than in *unicornis*. — The larva is very different; green, with a purple brown dorsal band of the first 3 segments, behind the dorsal appendage with an equally broad white stripe which is edged with brown, the sides being speckled brown. Described from Texas.

apicalis. **S. apicalis** *Grt. & Rob.* (149 e). Forewing reddish brown or greyish-brown, strewn with white, with a black basal ray and a white median area; the black cell-end streak is thicker and more bent than in *unicornis*, behind it a spot of darker dusting with dark brown internerval stripes to the margin; the posterior transverse line is white. Hindwing white with a large dark anal spot. From Maine, New York, Arkansas, and Florida; nothing is known of its life-history.

leptinoides. **S. leptinoides** *Grt.* (= *mustelina* *Pack.*) (149 e). Forewing ash-grey, mixed with whitish in the median area, brownish at the inner margin; the discal streak is black like the branches proceeding from it; the posterior transverse line is double, dentate, dirty white, the veins behind it black. Hindwing white, smoky at the distal margin with a dark anal spot. The ♀ is more lead-coloured, with obsolete transverse lines, the discal dot small, the distal margin somewhat lighter with blackish or also red-brown wedges between the veins. — Larva brown, with a purple brown dorsal stripe as far as the protuberance on the 4th segment, behind it with oblique streaks directed posteriorly downward, and a posteriorly open V-mark from the 8th to 10th segments. It chiefly lives on Hickory and walnut, but also on all sorts of other foliage trees. Maine to Georgia, to the west as far as Illinois.

biedermani. **S. biedermani** *B. & McD.* (= *clammenhoa* *Dyar*) (149 f) is a very large species with grey forewings mixed with somewhat red-brown especially subterminally, a black basal ray and discal streak and double black fine transverse lines, the anterior one more in round bows, the posterior one dentate, filled somewhat lighter; behind the cross-vein streak is a spot of darker dusting and 2 red-brown longitudinal rays above and below the median radial branch to the margin, before which there are black internerval streaks partly distally edged narrowly with white; a thicker black streak subapically in the somewhat lighter grey apex. Hindwing white with a black anal spot. Arizona, Mexico.

68. Genus: **Litodonta** *Harv.*

Chiefly separated from the preceding genus by the hairy though tuftless head, and the antennae being pectinated to the tips. Wings short and broad, neurulation as in the preceding genera, vein 5 of forewing from the centre of the cross-vein, the costal vein of the hindwing arises a little before the cell-end.

Type of genus: *L. hydromeli* *Harv.*

hydromeli. **L. hydromeli** *Harv.* (149 f). Forewing yellowish olive, with 3 fine double black transverse lines, a curved discal streak and grey strewing behind it and also at the inner margin; a submarginal row of blackish spots, somewhat more coherent in a lunar shape towards the costal margin. Hindwing white, feebly smoky at the margin. In two generations in Texas and Florida. — f. **fusca** *Harv.* is a much darker blackish form, and — *contrast.* f. **contrast** *B. & McD.* is likewise a dark form with smoky brown forewings, the transverse lines filled with white at the costal margin, the posterior one quite indistinct and interrupted, a white spot at the apex, the submarginal spots yellowish in the dark ground. From Arizona.

centigerna. **L. centigerna** *Schs.* Head and thorax greyish-brown, frons darker; abdomen white, mixed with cinnamon, forming transverse bands towards the base, white beneath. Forewing white with brown lines; sub-basal line feeble, the antemedian area brown, mixed with white below the cell; anterior transverse line double, dents of the interior line extend almost to the base; median area dark brown at the costal margin, below it only strewn brown, with a fine line in the cell; postmedian line brown, double, distally angled on 7 and 3; the cellular branches are blackish-brown; the deeply dentate subterminal line is white. Hindwing white, fawn-coloured at the distal and inner margins. Expanse of wings: 27 mm. Brazil (Rio Purus).

nigripuncta. **L. nigripuncta** *Schs.* (149 f) differs greatly from the other species. Forewing whitish, strewn with grey, the median area darkened steel-grey, with indistinct, light-shaded transverse lines and 2 thick black dots at the base, 2 at the apex, one at the inner angle and a thick round one at the cell-end. Hindwing white, brown in the female. Brazil (Paraná, Matto Grosso).

L. gigantea B. & Benj. is larger than the preceding species. Forewing violettish greyish-white, densely strewn with blackish with almost quite obsolete transverse lines, only the undulate line is slightly shaded darker; a black basal ray on the inner-marginal vein is somewhat lighter whitish above, the cross-vein marked by a fine black crescent; veins scaled blackish as far as into the fringe. Hindwing dingy brown with darker speckled fringe. Expanse of wings: 43 mm. Arizona.

69. Genus: **Psilacron** Fldr.

This genus is united with the genus *Hardingia* Schs. now. Two thirds of the antennae pectinated, palpi porrect with a short terminal joint; wings longer and narrower than in the preceding genus, the areole proceeds only behind the upper cell-end. Vein 6 arises near its base, the lowest subcostal branch is forked with the next. Hindwing as in all the preceding genera, but the veins 3 and 4 arise distinctly separated.

Type of genus: *P. luteovirens* Fldr.

P. luteovirens Fldr. (= *cosmipennis* Dyar) (149 f). The whitish ground of the forewing is finely strewn with red-brown, dusted with olive green subcostally, along the median vein and the submedian fold, with brown double dentate transverse lines and a brown rectangularly broken median shadow; a brown crescent at the cell-end; an oblique brown subapical shadow extends inwards and meets the postmedian shadow at vein 4, 3 small brown internerval spots are below it. Hindwing smoky brown with a light postmedian shadow, dusted red-brown at the inner margin, with white fringe. Peru and Bolivia.

P. congalla Schs. (149 g) is similar to *luteovirens*, smaller, forewing broader with a rounder distal margin. Forewing suffused with yellowish olive, the base of the costal margin striped violettish-grey; the brown lines similar to those of *luteovirens*, the median one angular, ending above vein 1 between two small white, darker edged spots. Hindwing suffused with brown, darkened at the margin. Bolivia (Incachaca).

P. chacona sp. n. is very near to *congalla*, but it has still much narrower forewings with a more pointed apex and a more oblique distal margin than *luteovirens*. Forewing whitish, in some places with an extremely faint pinkish lilac hue, the markings as in the allies, but all light moss-green, also the transverse lines, the median one rectangularly broken at the cell-end, the median vein and the submedian fold in the median area broadly moss-green; round black subterminal dots in the anterior half of the wing, below the uppermost of which there is a very dark greyish-black apical oblique shadow as far as the postmedian line. Hindwing all white, with a faint grey marginal band. According to 2 ♂♂ from the Chaco (La Paz), 3000 m (GARLEPP leg.) in the Coll. STGR. in the Berlin Museum.

P. gordiana Schs. (149 g) is much larger than *luteovirens*, wings shaped as in *congalla*, with darker hindwings; forewing much more intensely and monotonously suffused with moss-green, which colour is pale yellowish olive in SCHAU'S type which we figure, the markings in general as in the preceding species, though less conspicuous on the dark ground. Colombia (Mt. Tolima, Quindiu Pass).

P. agcistrum Dyar seems to be very closely allied to *gordiana*. Forewing light purple, darker at the base, with 3 green spots which are submedian, at the lower cell-end and below the distal third of the costal margin; with double dentate purple brown transverse lines and a faint crescent at the cell-end; the posterior transverse line is filled with white; the indistinct median shadow is curved at the cell-end, but not rectangularly broken; 3 white dots are on the submedian vein in the median area; a few purple subterminal spots, a white spot below the centre of the margin, and a white oblique subapical blotch. Hindwing brownish-grey, red-brown at the inner margin, fringe whitish. Expanse of wings: 45 mm. South-Eastern Peru.

P. melita Drc. (149 g) has greenish-grey forewings with a red-brown band from the centre of the inner margin to the median vein, from where it extends forked like a Y to the costal margin; a submarginal row of white, black-centred spots; fringe red-brown. Hindwing white. South-Eastern Peru.

P. arthuri Schs. Forewing grey, reddish olive yellow at the base, submedianly, in the median area, behind the lower cell-end, and at the anal angle; a black basal dot below the cell and a darker brownish-grey shadow behind it; transverse lines double, blackish-brown, the posterior one interrupted, broadly shaded blackish-brown behind it above the centre; the upper half of the margin is shaded dark grey. Hindwing brownish-grey with a double postmedian line filled with greenish at the costal margin. The ♀ is darker olive brown with a large white anal spot. Expanse of wings: 37 mm. Costa Rica.

P. discolor Schs. Forewing yellowish-green, shaded dark grey in and below the cell in the median area, a similar shadow is in the upper subterminal half, and black dusting before the centre between the cell and the inner margin; a velvety black moon-spot at the cell-end, grey shading below it proximally; a double curved

postmedian line is only visible in the upper two thirds. Hindwing brownish. Forewing of ♀ spotted white analwards. Expanse of wings: ♂ 41, ♀ 47 mm. Costa Rica. This may be only a form of the following *roberti*.

roberti. **P. roberti** Schs. (149 f) has reddish olive green forewings, mixed with grey in the basal area and under the lower median branch, with a large blackish-brown subapical spot, red-brown shading at the cell-end; rather indistinct dentate double transverse lines. Hindwing brownish-grey with a lighter postmedian shadowy line. Colombia.

eugraphica. **P. eugraphica** Dyar (149 g) is violettish-grey on the forewing, mixed with yellowish-green, the most distinctly so under the lower cell-end, and with darker shading in the cell; a round black spot in the basal area; transverse lines brown, the interior double one only distinct in the inner-marginal half, the distal one single; instead of the undulate line there is a dark brown dentate band in the costal-marginal third and a smaller spot above the anal angle; the margin before the speckled fringe is dusted with violet. Hindwing light grey, dark brown at the anal angle, the beginning of a dark postmedian line begins at the costal margin and is bordered with light on both sides. Mexico.

aphretesa. **P. aphretesa** Dyar reminds us of a *Disphr. atrax* or *dolorosa*: forewing light grey, whitish at the base and in the basal half of the costal margin, dusted with olive green apically, with double olive grey transverse lines, the interior one obsolete in the cell; one small olive lunulate spot each in the cell and at the cell-end; a series of olive grey spots behind the postmedian line; undulate line whitish. Hindwing grey, slightly scaled in the disc, whitish at the costal margin with grey double streaks. Expanse of wings: 50 mm. Mexico.

plagimargo. **P. plagimargo** Dyar. Forewing brownish olive, shaded with purple brown at the inner margin and subterminally, the inner margin defined on the submedian fold upwards by a jet-black streak; of the transverse lines only the rectangularly curved median line is distinct, black, a black spot is above the anal angle, two white spots behind it and above it; fringe speckled black. Hindwing light purple brownish with a feeble whitish median shadow. Expanse of wings: 48 mm. Mexico.

macarisma. **P. macarisma** Dyar (149 g) is very similar, dark greenish-grey with a large white spot in the anal half of the margin, with rusty yellow spots subterminally and at the margin, black veins and a thick black basal submedian streak; of the transverse lines only the black dentate undulate line is somewhat more distinct, white vein-dots are behind it. Hindwing as in *plagimargo*. Mexico (Zacualpan).

maculosa. **P. maculosa** Dogn. Forewing greenish greyish-brown, with rusty yellow spots, instead of the transverse lines with lighter bands the posterior one of which is spot-like, a black streak in a light spot is at the cell-end; a dentate brown line is in the yellowish-white marginal area. Hindwing dirty white, grey at the margin. Expanse of wings: 46 mm. French Guiana.

monostigma. **P. monostigma** Dyar has the antennae pectinated almost to the tips. Forewing light greyish-green with small white spots at the base of the costal margin and on the submedian fold, parts of the inner margin are strewn with black; a darker shadowy spot is behind the black and brown cross-vein streak; the exterior dentate brown transverse line is irregularly marked; fringe speckled black. Hindwing dark greyish-brown. Expanse of wings: 40 mm. Mexico (Hidalgo).

hidalgoa. **P. hidalgoa** Dyar (149 g). Forewing grey, feebly dusted green and strewn black with a black cross-vein luna surrounded with brown, and a small white costal-marginal spot above it; the dark double dentate transverse lines are rather indistinct, a series of small subterminal dark internodal spots is more distinct. Hindwing whitish, grey at the costal and inner margins with the beginnings of a light postmedian band. Mexico (Hidalgo).

cincia. **P. cincia** Drc. (149 h) has a scheme of markings similar to that of the following *mechanica*, but the colours of *D. manethusa*. Forewing whitish, scantily strewn with rusty yellowish olive — probably green in the fresh specimen —, strewn with blackish grey in the distal third of the cell and between the submedian fold and vein 4, olive green in the basal area from the base of the costal margin to the centre of the inner margin, distally defined by a very oblique darker olive line of a slightly undulate course, a parallel double antemedian line behind it, the interior portion olive, the exterior one blackish; a darker lunule at the cell-end, 3 undulate lines behind it are indistinctly marked by accumulated darker atoms; apex more densely dusted with rusty yellowish olive; the veins in the marginal area interrupted by blackish. Hindwing thinly scaled white, inner margin and apex smoky, 2 short olive lines before the apex. Colombia (Rio Negro), Bolivia; South-Eastern Peru.

mechanica. **P. mechanica** Dogn. (= *ockendeni* Drc.) (149 h). The whitish ground of the forewing is strewn with grey, darker and more or less dusted with rusty brown at the base and postmedianly, with double dentate transverse lines and a black discal crescent above which there is a small white spot in black costal-marginal streaks; fringe speckled. Hindwing white. Ecuador and Colombia.

P. divisa *Rothsch.* (149 h) is a very different small insect which probably belongs to another genus; *divisa*. forewing chestnut brown with numerous very indistinct blackish, partly confluent transverse lines composed of single lunules, a small black cell-end spot and a yellowish streak behind it. Hindwing brownish-black. Amazons, Peru and Bolivia.

P. sericeus *Rothsch.* (149 h) reminds us of the common *D. laeca*, forewing light reddish-yellow strewn *sericeus*. with grey, dark reddish chocolate and strewn with reddish-yellow in the costal-marginal part, somewhat lighter in the centre of the costal margin, with a large light reniform macula; the dark transverse lines are indistinct, double, dentate. Hindwing red-brown. Peru.

70. Genus: **Urgedra** *Dyar.*

The ♂ antennae are pectinated very long, palpi porrect with a short terminal joint. Shape of wings broad triangular with an entire margin and a similar neuration as in the preceding genus, vein 5 from the centre of the cross-vein, 6 from the basal third of the very long and narrow arcole from the end of which the lowest subcostal branch proceeds, the next 3 on a joint stalk; hindwing as in *Psilacron*, the costal vein arises before the centre of the cell. A number of irregularly coloured and marked species which are often green.

Type of genus: *U. striata* *Drc.*

U. striata *Drc.* (= *pavimenta* *Dogn.*) (149 h). Forewing brown intermixed with white and yellowish- *striata*. green scales, the basal third and a broad postmedian band darker brown, the median area between them somewhat more reddish, the cell-end streak brown, surrounded by yellowish-green; the brown postmedian band is edged by a white line on both sides, the interior line of which is strongly dentate, the veins crossing it are set with raised scales, so that the interspaces look like small locules; brown marginal lunules are surrounded with greenish-yellow, fringe speckled white. Hindwing red-brown, lighter towards the base, fringe speckled. Colombia (Socorro, Cali). — f. **quindinata** *Dogn.* differs from *striata* in the absence of the white and yellowish- *quindinata*. green scales, the interior one of the two white lines is scarcely dentate. Expanse of wings: 41—42 mm. From the Quindiu Pass.

U. albodiscata *Dogn.* (149 i) has the same ground-colour as *striata*, some veins are finely strewn with *albo-* white, a small spot in the centre of the cell and the cross-vein streak are white; the white border-lines of the *discata*. brown postmedian band are absent, but there are 2 black dots edged with greenish-white before it on the submedian fold. Hindwing red-brown, fringe white at the ends of the veins. Expanse of wings: 37—39 mm. Quindiu Pass.

U. chaon *Drc.* The light brown forewing is strewn with black and green scales. Two tiny white spots *chaon*. are at the cell-end; a submarginal row of white dots. Hindwing reddish-brown, lighter basal. Colombia, Peru.

U. brunnea *Drc.* Forewing dark red-brown, strewn with light greyish-brown, with a white cell-end *brunnea*. streak and a submarginal row of large dark brown internerval spots. Hindwing blackish-brown, fringe somewhat lighter. Peru.

U. oslaca *Schs.* (149 k) is a deviating large species. Head and thorax brown, abdomen blackish-brown. *oslaca*. Forewing dark brown, yellow scales at the costal margin, and 4 oblique streaks towards the apex; antemedian line blackish-brown, angled distally, where it is scaled white and yellow; a white and yellow streak at the cross-vein; the white subterminal line is strewn with yellow on the veins; the brown marginal line is scaled bluish-white inwards, interrupted on the yellowish veins of the marginal area. Hindwing brownish red. Bolivia (Incachaca.)

U. fremida *Dogn.* (149 i) has somewhat longer wings which are greyish brown, densely strewn with *fremida*. yellowish, subcostally white scales, single veins are very finely striped white, with a black cell-end streak at both ends of which there are white dots; transverse lines double, the anterior one broken up into dots, the darker postmedian band is more densely strewn with light scales at its edges, with white dots outside at the dents; fringe grey traversed by white. Hindwing brown. Expanse of wings: 40—45 mm. Colombia (San Antonio, Cali).

U. dissolvens *Dogn.* (149 i). Forewing dark red-brown, white and green subcostally, strewn with green *dissolvens*. postmedianly and around the subterminal spots; the inner-marginal vein, the centre of the median vein and the veins 6 and 7 are striped lilac white, the median area is edged by two darker brown bands, the postmedian one traversed by white veins, bordered at the edges with black dots, the interior dot above the inner-marginal vein thicker than the others; the median area is traversed by several fine darker transverse lines; brown submarginal internerval lunules are surrounded by green. Hindwing brown. Expanse of wings: 36—38 mm. Colombia (Socorro, Cali).

dissociata. **U. dissociata** Dogn. (149 i) is very similar to the preceding species, the colour is greyer, more white, scarcely strewn with green, the postmedian band distally bordered with white, the anterior band straighter, with internerval dots; the costal margin is white, traversed by brown streaks; a fine subterminal line, no lunular row; fringe more distinctly crossed by white. Hindwing grey, not brown, yellowish-white beneath, brown in *dissolvens*. Expanse of wings: 40—41 mm. From the same habitats.

multilineata. **U. multilineata** Drc. (149 i) was described as a *Heterocampa*, but according to the excellent photo of the type, which was put at our disposal by the great kindness of Messrs. JOICEY and TALBOT, it belongs near *dissolvens*. The ground-colour is greyish-white, a red-brown spot is at the base below the cell, traversed by the same dentate lines as in *dissociata*, 3 postmedian lines, the middle one very thin, the third very thick and blackish-brown, thickened at the inner margin, in the middle and subcostally, bordered with yellowish-white distally, red-brown dusting before the thin blackish-brown submarginal line. Hindwing light brownish-grey. South-Eastern Peru.

permixta. **U. permixta** Dogn. (149 i) is likewise very near to *dissolvens*, but smaller and less contrastingly marked; forewing brown strewn with light green, forming a brilliant green spot at the base, adjoining to it the double antemedian line; the light brown median area is dusted with white; between the two distal double transverse lines there is a darker brown postmedian band on which green strewing in the inner-marginal half forms again a green spot dusted with white distally; a dark dentate line is in the green margin. Hindwing red-brown, fringe traversed by whitish. Expanse of wings: 33 mm. Colombia (Quindiu Pass).

viridiflava. **U. viridiflava** Dogn. (= *luceria* Drc.) (149 i). Forewing light yellowish-brown, feebly dusted with lilac, with brown double transverse lines filled with green, the postmedian line intensely bordered with green outside, the marginal row of brown lunules also dusted with green distally. Hindwing light brown. Expanse of wings: 35—40 mm. Colombia (Socorro, Cali).

nabora. **U. nabora** Schs. (149 i) is near to *viridiflava* from which it chiefly differs in the metallic green, not dull green, scales. Forewing light cinnamon; the metallic green colour occurs in the basal third subcostally and before the antemedian line, then broadly before the distal line and at the small brown subterminal spots; transverse lines brown, the anterior line more distinct only in the inner-marginal area, the median line likewise indistinct, the postmedian line double, the posterior line bordered with white distally; a blackish-brown dot in the centre of the cell, a dark line at the cell-end. Hindwing tan-coloured, base and costal margin whitish. Expanse of wings: 37 mm. Colombia (Mt. Tolima).

viridinigra. **U. viridinigra** Dogn. Forewing blackish-brown, uniformly strewn with green and white, with rows of black dots instead of the transverse lines, the last filled with green, with a cellular dot and two at the cell-end, the latter two distally white. Hindwing blackish. Expanse of wings: 40—44 mm. Distributed in Colombia.

palmeri. **U. palmeri** Drc. (149 k) is easily recognizable by the yellow margin which is twice angled inwards; forewing reddish-brown, dusted with yellow at the apex and inner margin, with 3 indistinct brown undulate lines; the yellow margin is separated from the brown part of the wing by a white line. Hindwing yellowish-grey, brown at the costal and inner margins, with a red-brown anal spot and yellow fringe. West Colombia.

71. Genus: **Misogada** Wkr.

Allied to the preceding genus, but the antennae are shorter and not quite pectinated to the tips, palpi longer in the ♂ than in the ♀. Forewing narrower, vein 6 arises from the centre of the areole; the costal branch of the hindwing proceeds near the cell-end.

Type of genus: *M. unicolor* Pack.

unicolor. **M. unicolor** Pack. (= *marina* Pack., *cinerea* Schs., *sobria* Wkr.) (149 k) is unicoloured light grey with a green tint, or strewn with grey on a greenish ground, all the tints varying as far as dark purple grey with somewhat darker punctiform transverse lines; a subterminal row of small dark irregular, distally white spots. Hindwing greyish-white. The green larva is humpless, with a broad yellowish-white dorsal band bordered with reddish; the claspers are very long and slender. It lives on plane-trees in 2 generations, the imago in May, June and August. Atlantic States.

signifera. **M. signifera** Dogn. Forewing grey, with two black dentate, partly faded antemedian parallel lines and a black cell-end streak surrounded by yellow; the postmedian line is rather indistinct; interrupted, and followed by a row of white vein-dots; a broad obsolete subterminal band. Hindwing whitish with a blackish margin. Expanse of wings: ♂ 23, ♀ 29 mm. French Guiana.

tridiscata. **M. tridiscata** Dogn. has blackish-grey forewings with obsolete darker transverse lines and 3 black dots at the cell-end, the third, however, may also be absent. Hindwing white with a broad grey marginal band, traversed by light at the anal angle. Expanse of wings: 24 mm. Amazons.

M. brioca Schs. Head and thorax white, mixed with reddish yellow, 2 small metathoracal tufts bordered *brioca*. with blackish-brown, the centre iridescently scaled. Abdomen white above, strewn with reddish-brown, white beneath. Forewing white, scantily strewn with reddish-brown, more profusely at the inner margin and in the centre of the costal margin; transverse lines brown, the anterior one double, its interior portion very feeble, dentate, ending at the inner margin near the posterior one which is single, a narrow reddish-brown shadow behind it; a brown subterminal shadow and a strongly undulated marginal line. Hindwing whitish, reddish-brown at the distal margin. Expanse of wings: 31 mm. Argentina.

M. pallida Schs. Forewing whitish with an olive tint and brown dentate transverse lines, the exterior *pallida*. one more distant from the apex than from the anal angle, and a submarginal row of small internerval spots; a fine black-dusted lunular streak at the cell-end. Hindwing brownish-white, more brownish at the margin. Santiago de Cuba.

M. blerura Schs. has whitish forewings strewn with olive green, similar to those of *pallida*, with a broad *blerura*. olive green antemedian band bordered with black, followed by a fine olive green line which is fused at the inner margin with a similar postmedian line; this is followed at the inner margin by a short black line, above which there are some vein-dots, a blackish shadow towards the costal margin; one black dot below the base of the cell, two at the cell-end. Hindwing whitish, smoky at the margin. Expanse of wings: 30 mm. Brazil.

M. nigrifulva Dogn. is a small species, the basal third of the forewing blackish except the base and a *nigrifulva*. submedian spot, both the spots as well as the rest of the wing are reddish olive, lighter towards the costal margin; the lower cellular branches are partly brownish, a black dot at the cell-end. Hindwing brownish. Expanse of wings: 28 mm. French Guiana.

72. Genus: **Notoplusia** Schs.

Two thirds of the ♂ antennae set with short hairy pectinations, the hairy palpi reach to the vertex. Forewing with an almost straight costal margin; vein 5 is removed up to the upper cell-angle, 6 arises from the centre of the areole; hindwing as in the preceding genera. A small number of partly very similar tropical species.

Type of genus: *N. clara* Cr.

N. clara Cr. (149 k) is easily recognisable, very different from the other species, the brown forewing *clara*. with black longitudinal stripes and a large triangular silvery white spot in the disc. Guiana, Colombia.

N. marchiana Schs. is extremely similar to *clara*, discernible by the antennae being tuftedly ciliated *marchiana*. in the basal halves, not shortly pectinated. The broad black subterminal line of the forewing forms internerval lunules, only one between 6 and 4, behind it follows a fine red-brown lunular line, interrupted on the veins. Hindwing whitish, brownish sand-coloured at the margins, narrowly so at the distal margin. Expanse of wings: 40 mm. Colombia (Eastern Andes); Bolivia (Rio Songo). Genitally very different from *clara*.

N. eugenia Schs. Basal part of forewing, from the first quarter of the costal margin to the centre of the *eugenia*. inner margin, dark brown with velvety darker stripes, reddish-yellow behind it, lilac at the costal margin, strewn with brown below it, cell-end whitish, with an oval brown line; the posterior transverse line is fine, dark brown, shaded with brown and grey behind it, with velvety darker internerval streaks; undulate line whitish, widened between the veins 4 and 6. Hindwing dark grey. Expanse of wings: 27 mm. French Guiana.

N. eunoteloides Schs. Forewing grey, basal third excepting the inner margin dark brown, bordered by *euno-* a darker brown line which is distally edged with white; a brown reniform macula at the cell-end, one dark brown *telo-* spot each behind the centre at the costal margin and inner margin, the lower one larger; vein 6 black; the *ides*. straight undulate line is black, anally twice interrupted inwards. Hindwing whitish with brownish veins and margin. Expanse of wings: 33 mm. Costa Rica.

N. oyapoca Schs. (149 k) almost looks like *eunoteloides* and may be only a form of it; a more distinct *oyapoca*. dentate median line extends around the reniform macula which is distally scaled somewhat brownish; the black streak on the uppermost radial branch is thicker and longer and coherent with the brown costal spot; above its distal end there is another smaller brown spot, the median radial branch is also striped black towards the margin, the veins below it are strewn somewhat black; subterminal line more interrupted, not straight in its upper part, but undulate. Hindwing dusted brownish-grey, especially at the inner margin. French Guiana, Bolivia, Matto Grosso.

N. boliviensis Schs. (149 k) is likewise similar to the preceding species, the olive grey ground slightly *boli-* tinged with brownish postmedianly, basal area light brown with a double black subbasal line in it, followed by a *viensis*. brownish-black antemedian shadow followed by a similar line, 2 fine dentate transverse lines are in and behind the centre, behind the latter a short costal-marginal lunule instead of the large costal-marginal spot of the

preceding species; the subterminal inner-marginal spot is large, the subapical black vein-streaks and the undulate line as in *eunoteloides*, the lower half of the undulate line broken up into single spots. Hindwing whitish, costal margin and veins brownish. Bolivia.

sabrena. **N. sabrena** Schs. Forewing reddish-yellow, densely strewn dark brown forming a broad costal-marginal shadow before the centre and a subterminal spot; a dark dot at the cell-end, traces of interrupted double transverse lines before and behind the centre, large dark internerval spots at the margin. Hindwing dark grey, lighter towards the base. Expanse of wings: 34 mm. French Guiana.

talmecana. **N. talmecana** Schs. is an entirely different species similar to the species of the genus *Talmeca*. Head and thorax reddish-yellow with an olive brown longitudinal line; abdomen brownish-red, ventrum white. Forewing light reddish-yellow, median vein white, finely striped brown above, yellow beneath; grey stripes strewn with black in and below the cell; feeble darker antemedian and postmedian transverse lines and a dentate distal line, the latter distally bordered with white; subterminally with dark dots and brownish-black vein-streaks; a dark blotch along vein 5 to the margin. Hindwing brownish grey. Expanse of wings: 35 mm. Brazil (Rio Purus).

73. Genus: **Dognina** Schs.

Antennae pectinated only in the basal halves, the hairy palpi very short. Anal angle of forewing typically somewhat convex; vein 5 arises above the centre of the cross-vein, 6 behind the centre of the very long and narrow areole. Costal margin of hindwing very obtusely rounded, neuration as in the preceding genera.

Type of genus: *D. veltini* Dogn.

veltini. **D. veltini** Dogn. (149 l). Forewing lustrous light greyish-brown with two mostly light transverse lines which are very near together at the inner margin and proceed from large dark brown costal-marginal spots; a whitish lunule at the cross-vein, a more or less distinct shadowy median line behind it; the inner-marginal beginnings of the transverse lines are bordered with dark brown on both sides, the fringe is speckled white in the lower half. The species is variable, the forewing often shows a white-dusted spot above the anal angle. Hindwing greyish-brown with whitish fringe finely speckled brown at the ends of the veins. Colombia, Bolivia, Ecuador.

carastia. **D. carastia** Drc. Forewing dark brown, grey at the inner margin and anal angle, with a broad black, grey-strewn transverse band near the base. Hindwing dark brown with lighter fringe. Peru.

botis. **D. botis** Drc. is described to be greenish-black, with a large white basal spot, a very large red-brown spot bordered with white, and a red-brown apical spot bordered with white inside, the distal margin reddish-brown. Hindwing dirty white, darker at the costal margin. Peru. The species is probably synonymous with *achates*.

achates. **D. achates** Dogn. (149 l). The description almost coincides with that of *botis*; the white interior border of the large spot of the median area is continued as a round line at the costal margin into the interior border of the triangular subapical spot; a whitish subterminal shadow is in the reddish-brown distal area, and the fine continuation of the white line subterminally parallel to the margin. Peru, Brazil.

bella. **D. bella** Jones (149 l) is almost the same as *achates*, forewing white, dusted light reddish-brown, with an olive green, centrally strangulated band, distally defined by a white line which is curved around an olive green triangular spot near the apex at the costal margin; subterminal violettish-grey dusting without the white line of *achates*. Expanse of wings: 38 mm. Parana.

peruda. **D. peruda** Drc. (149 l) is likewise near to the preceding species. Forewing white with an olive green antemedian band which is bordered with black and narrower in the middle; a black spot at the cell-end and an olive green spot behind it at the costal margin. Hindwing white, yellowish brown at the inner margin. Venezuela, Colombia, Bolivia.

74. Genus: **Hemipecteros** Schs.

♂ antennae bipectinate with ciliary tufts on the outside, palpi short, covered with scales; forewing with a rounded distal margin, vein 5 arises from the centre of the cross-vein, 6 from the centre of the areole; hindwing triangular with a rounded costal margin and with the usual neuration, veins 6 and 7 only on a short stalk, the costal vein proceeds from the centre of the cell.

Type of genus: *H. arthemis* Schs.

arthemis. **H. arthemis** Schs. Forewing white, strewn somewhat grey basally and in the median area, with a grey antemedian area as far as the double anterior transverse line; the posterior line is likewise double, reddish-

brown or blackish-brown, finer and darker in the lower half, distally shaded with brownish-grey in the upper half, widened towards the costal margin and subcostally traversed by two black vein-streaks; a large dark brown longitudinal spot at the cell-end is scaled ochreous; large white subanal spots enclosing black marginal spots which extend into the white fringe. Hindwing iridescent white with yellowish inner margin and veins and a small dark anal spot. Expanse of wings: 40 mm. British Guiana.

H. teffeina Schs. Body drab, intermixed with white and brown. Forewing white, strewn with drab *teffeina*. and blackish-brown, double transverse lines and the discal lunula fine black, all filled with reddish yellow; marginal area dusted with brownish with a fine undulated black marginal line. Hindwing white with a narrow light brownish apical shadow and a brown anal spot with a blackish-brown lunular spot behind it; marginal veins fine brown. Expanse of wings: 47 mm. Amazons (Teffé). Closely allied with *arthemis*.

H. gastriva Schs. looks like the preceding species, but it is darker and differs from the diagnose of the *gastriva*. genus in the antennae being pectinated only on the inside, serrate outside; forewing grey, strewn darker, brownish at the margin, the anterior transverse lines only feebly marked, but a distinct double median line is present, thickened below the cell and dentate distally above the inner margin. Hindwing grey, strewn with brown, with brown veins and marginal line and a blackish anal spot parted by light. Expanse of wings: 45 mm. Dutch Guiana.

H. albifera Dogn. (= *vatsoni* Schs.). Forewing violettish-brown, mixed with whitish at the base, with *albifera*. 4 blackish antemedian transverse lines; a yellowish-white streak at the cross-vein is bordered with dark brown inside, distally to it a fine brown line which extends from the costal margin to the inner margin; the marginal line is white, scantily strewn with brown, bordered by a double black line which is filled with steel-grey and extends inwards curved from the apex to the anal angle. Hindwing brownish-grey with white fringe. Expanse of wings: 39 mm. Guiana.

H. semialba Drc. (149 l) has violettish-brown forewings strewn with white basally as in *albifera*, with a *semialba*. black dentate postmedian line behind which a large white area follows, which reaches neither the apex nor the anal angle and is strewn somewhat grey in the middle; the white fringe behind the black marginal line is traversed by black at the ends of the veins. Hindwing white with a grey anal spot. Peru, Brazil.

H. similis Dogn. (= *dyari* Schs.) resembles the two preceding species, but the marginal area is more *similis*. intensely strewn with brown, its interior black border-lines are parted towards the costal margin and followed by a straight brown subcostal line; instead of the blackish-brown marginal lunae of the preceding species there is a line here, which is straight in its upper half, undulate below it. Hindwing white with brown veins and marginal line, and a brownish anal spot. Expanse of wings: 43—44 mm. Venezuela.

75. Genus: **Trumanda** Dogn.

Only half of antennae pectinated, the hairy palpi short. Forewing long and rather narrow, with long hair below in the cellular half and on the submedian line; neuration as in the preceding genus, but vein 6 proceeds only behind the centre of the areole. Hindwing almost quadrangularly cut off at the apex, distal margin somewhat concave in the centre, the veins arising from the upper cell-angle are not stalked. Only two species.

Type of the genus: *T. fifiana* Dogn.

T. fifiana Dogn. (150 a) (= *stigmatica* Rothsch.). Forewing light yellowish-brown at the costal margin *fifiana*. and in the distal half, yellowish pink as far as the centre of the cell, light yellow in the distal half of the cell, with a darker double anterior transverse line extending through the centre of the cell; a double brown cross-vein streak at the cell-end, and a brownish ochreous spot of broad modified scales in the lower half of the median area, like a scent-scale spot, finely bordered with white distally; fringe white, traversed by brown on the veins. Hindwing diaphanous white, more densely scaled yellowish-white at the costal and inner margins. French Guiana.

T. schiffi Schs. Head and thorax white, intermixed with single sand-coloured hairs; abdomen yellowish- *schiffi*. white. Forewing white, spotted grey at the costal margin instead of the beginnings of the lines, strewn with sand-colour basally and antemedianly; subbasal line grey, bordered with a pure white inside, a drab spot behind it at the inner margin, anterior transverse line double, black in the cell, grey below it, filled with white; a black streak at the cross-vein, the veins 3—8 as far as the subterminal line also black; the spaces between 4 and 8 white, transparent, traversed by a fine double black postmedian line; small orange brown spots behind vein 2 and below 5; subterminal black spots, a white line behind it, bordered with brown on both sides. Hindwing transparent white, with reddish-yellow hairs at the inner margin, a short black line at the costal margin. Expanse of wings: 48 mm. Colombia (Buena Vista).

76. Genus: **Trichomoplata** Wing.

Like the preceding genus, but two thirds of the antennae pectinated, forewing still longer and narrower with a very pointed apex and an oblique distal margin; neuration the same as in *Hemipecteros*.

Type of genus: *T. vittata* Wing.

- vittata*. **T. vittata** Wing. (= *tigniferum* Fldr.) (150 a) is unmistakable; forewing yellowish-white, with a purple brown inner margin and a similarly coloured oblique band above it from the first quarter of the costal margin to the anal angle; the large very oblique reniform macula is at the cell-end, narrow black internerval wedges behind it. Hindwing white. Colombia, Peru and Bolivia.
- dimorpha*. **T. dimorpha** Rothsch. (150 a). Forewing diaphanous dirty white, the basal half somewhat more densely scaled yellowish-grey, feeble shadowy bands of similar scales are subterminal and at the apex; a large orange brown spot is at the base of the lower median branch. Hindwing diaphanous white, yellowish-grey at the costal and inner margins. The much larger ♀ is more reddish-brown, only postdiscally diaphanous whitish, the dentate shadowy bands brownish, the spot is hemochrome, a rusty brown spot below it. Amazons.
- cassiope*. **T. cassiope** Schs. (= *phronima* Drc.) (150 a) is very similar to *T. fijiana*. Forewing light reddish-brown, crossed by 4 darker double zigzag lines, the most distal one shaded with smoky brown inside, a reddish-brown spot in the centre of the inner margin. Hindwing white, with red-brown hairs at the inner margin. Rio de Janeiro.

77. Genus: **Disphragis** Hbn.

This second-largest of all the Notodontid genera was formerly named *Heterocampa* Dbld. Some subordinate genera, such as *Lochmaeus* Dbld. and *Cecrita* Wkr., have been established for the numerous North American species, but in classifying the numberless tropical species this division cannot be well kept up, and so we must leave the grouping of the frequently very heterogeneous insects to a future exhaustive elaboration; we therefore keep to the large comprehensive genus in its original form.

About two thirds of the ♂ antennae, often also of the ♀, are pectinated, the pectinations often very long, often much shorter, so that there is no distinct boundary to the strongly serrate shape; for this reason a few species the exterior of which entirely agrees with *Disphragis* were ranged under the genus *Rifargia* which is only distinguished by the shape of the antennae, as for instance *gelduba*. The hairy palpi are rather short. The neuration is quite the same as in *Trichomoplata*, the difference from the preceding genus chiefly consists in the less elongate shape of the wings with a less pointedly produced apex, the abdomen being somewhat shorter, too. The larvae have generally the normal shape without protuberances or cones, only several species exhibit in the early stage thorns shaped like a stag's antlers on the first segment; the middle joints are often a little swollen, the claspers extended to long ends that can be turned out. As far as they are known, they live on all sorts of foliage-trees and pupate in a thinly woven cocoon between leaves.

Type of genus: *D. astarte* Dbld.

- astarte*. **D. astarte** Dbld. (= *menas* Harr., ♀ *chapmani* Grt.) (150 b) is very closely allied to all the following species. Forewing light olive green, with two double undulate black antemedian transverse lines, the space between them being often somewhat darker; at the cell-end there is a curved black crescentiform streak, a brownish-grey spot before it in the cell-end, followed by a threefold postmedian line with deep crescentiform bows, the two first distantly separated; the wing is subterminally lighter especially in the costal-marginal half, particularly in the ♂ and most intensely before the deep black undulate line; the marginal line composed of high crescents is very characteristic. Hindwing all white in the ♂, somewhat smoky in the ♀ with a darker marginal band and anal spot. The larva lives on oaks. The range is confined to Georgia, Florida, and Texas.
- varia*. **D. varia** Wkr. (= ♂ *obliqua* Pack.) (150 b) is very near to *astarte*, but it lacks the olive green colour altogether, being brownish ash-grey, more or less mixed with reddish-brown; the white crescentiform subapical spot is larger, its distal black border broader, less distinct, enclosing short black internerval streaks, continued to the inner margin, and here with a small white lunule before it, the black marginal lunae are much flatter than in *astarte*, hindwing not so pure white, but somewhat smoky. — f. **trouveloti** Pack. (= *brunnea* Grt. & Rob.) is a more distinctly reddish-brown form, the female with some olive admixture and more prominent marking, hindwing smoky grey. — f. **picta** Fldr. (= *perolivata* Pack.) (150 b) is a form very similar to *astarte*, with purely light olive green forewings, but with the large white subapical spot and its distal broad indistinct border as in *varia*, and with purer white hindwings. — The larva is dirty whitish, flesh-coloured, brown or green with a white dorsal band which is expanded on the second ring and between the 4th and 8th rings, and edged by red-brown lines. It lives on oaks. It occurs in the Northern Atlantic States, the form *picta* in the Southern States.

D. georgiana Dyar (150 b) is very similar to *varia*, distinguished by a more uniform, deeper black *georgiana*. discal luna, a more widened, less white, more greenish subapical spot which extends uninterrupted to the anal angle; the black subterminal internerval streaks are absent, the black marginal lunae consist of almost W-shaped zigzag streaks of a rather irregular shape. Larva very similar to that of *varia*, but the white, brown-edged dorsal band is more uniformly broad; likewise on oaks. Georgia, Florida.

D. barsypus Dyar is extraordinarily similar to *georgiana* and is scarcely a different species; the olive *barsypus*. green colour on the grey forewing is confined to a subapical blotch, a wedge-shaped spot above the anal angle and a spot below the cell-end; reddish-brown scales subbasally at the inner margin and in the cell-end, the black subterminal shadowy line is very strong, the black marginal line finely undulated, uniform and finely double. Hindwing dark grey, with white hair at the inner margin. Expanse of wings: 60 mm. North Carolina.

D. rufinans Dyar is another ally from this difficult group; forewing grey with a reddish-brown *rufinans*. spot near the base of the inner margin and another one in the lower half of the white subapical blotch; a fine black basal ray extends to the red-brown inner-marginal spot; the black double transverse lines are filled with a lighter colour, the black straight marginal striae in the lower half of the wing are scalariformly separated. Hindwing white, with a slight grey tinge at the apex and costal margin. Expanse of wings: 45 mm. Described according to a ♂ from Colorado.

D. simulans B. & Benj. (150 b) is regarded by the authors to be perhaps a race of *rufinans*; forewing *simulans*. dark violettish-grey mixed with red-brown, especially before the anterior transverse line, the subapical shadow somewhat lighter, the black marginal line only single. The fringe of the white hindwing is speckled black on the ends of the veins. Described according to a ♂ from West Iowa.

D. ditta B. & McD. (150 b) is a smaller species with blackish-brown wings, somewhat lighter basally, *ditta*. the centre of the costal margin strewn with grey, with a fine black curved cell-end streak and an oblique white subapical blotch. Hindwing white with a narrow black marginal line and speckled fringe. Arizona.

D. ruficornis Dyar has ash-grey forewings with 2 dentate blackish transverse lines which are bordered *ruficornis*. with whitish on the averted sides and extend similarly as in *astarte* and its allies; a curved black crescentiform streak at the cell-end is bordered with whitish on both sides; the apex is parted by a very indistinct blotch of a whitish colour, bordered above and inside by the beginning of a blackish undulate line in the shape of a semi-bow. Hindwing brownish-grey, a black spot parted by white is at the anal angle. Antennae bright reddish-yellow. Arizona.

D. subrotata Harv. (= *superba* Edw.) (150 c). Forewing brownish ochreous, strewn with black basally *subrotata*. and at the inner margin, median area lightest, purely yellowish ochreous; before the black crescentiform streak at the cell-end a broad smoky blackish shadow begins, extending curved with an upward concavity to the anal angle; 3 black internerval streaks behind the slightly curved white subapical blotch; the black transverse lines are double as in the preceding species. Hindwing dingy whitish, smoky in the marginal half, with a white post-median line. New York, Missouri, Alabama, Chicago, Illinois, Arkansas, Texas, Florida. — f. *celtiphaga* Harv. *celtiphaga*. is a smaller blackish olive grey form with a narrower white subapical oblique streak and a somewhat less distinct marking.

D. agapa Schs. is very closely allied to *subrotata* (150 c) and may be only a form of it. Basal area *agapa*. of forewing brownish-black and strewn with light brown as far as the black antemedian line, the median area behind it at the costal margin grey, light reddish sand-colour below it, with a fine velvety black median line which is incurved at the cross-vein and towards vein 2, more or less punctiform; a broad postcellular blackish-brown shadow from 8 to 2 and to the anal angle, distally bordered by the fine blackish-brown postmedian line; a broad white spot from vein 5 to the apex, dark spots behind it; marginal area blackish mixed with brown. Hindwing white, brownish at the margin. Expanse of wings: 28 mm. Mexico (Sinaloa).

D. belfragei Grt. (150 c) is very similar to the following species; forewing ash-grey, marked very *belfragei*. much like *lunata*, but much more distinctly and more profusely, with strong double black transverse lines, the postmedian line filled with lighter grey, the submarginal line interrupted on vein 4 as in the allies. Hindwing white with a fine black marginal line and dark-speckled fringe. Known from Texas and Arizona.

D. lunata Edw. (= *plumosa* Edw.) (150 c) is somewhat larger, more brownish-grey, markings less *lunata*. distinct, submarginal line broader, more blurred, not so much interrupted; the fine long black discal streak of *belfragei* is smaller here, thicker, more punctiform. Hindwing not so white, marginal line more faded, costal margin broadly smoky. Colorado and Arizona to Mexico. The ♀ is much more monotonous, often without any markings, hindwing smoky.

- umbrata.* **D. umbrata** Wkr. (= *athereo* Harr.) is considerably larger than the preceding species, but of the same scheme of markings. Forewing light ash-grey with an olive green tinge and a blackish curved shadow before the discal streak, extending as in *subrotata* beyond the anal angle, the ground-colour behind and below it being lightest; transverse lines and submarginal line as in *lunata*, the latter line broad, distinctly interrupted on vein 4, almost extinct at the costal and inner margins; fringe speckled dark at the ends of the veins. Hindwing slightly smoky in both sexes, darker at the margin with a distinct white postmedian line. — Larva thickened on the median segments, with two coniform tubercles behind the head, green, with 2 long dorsal spots which are filled with orange and bordered with purple brown, only interrupted on the 7th segment. It lives on oaks. Distributed from Pennsylvania, New York, Illinois to Florida. — f. **pulverea** Grt. & Rob. (150 c) differs in the entire absence of the olive green tinge, but it is more intensely strewn with black; the large light subapical crescentiform spot spotted red-brown is much more thickly bordered with black inwards, the fringe much more contrastingly speckled black and light. — f. **averna** B. & McD. (= *pasathelys* Dyar) is blackish-brown on the forewing, mixed with lighter and without any olive tinge, the light spot behind the cell darkened brown, the black submarginal line very strong, hindwing of a purer white colour, smoky only at the margin. Arizona, Mexico.
- incongrua.* **D. incongrua** B. & Benj. Forewing olive grey, mixed with red-brown and green, strewn with black on the veins, with a black basal ray and more or less faded double black transverse lines, the submarginal line represented by black internerval sagittae similarly as in the preceding species; the black crescentiform cell-end streak is distinctly surrounded with red-brown. Hindwing white, strewn with blackish on the veins and margin. New Mexico, Arizona.
- cubana.* **D. cubana** Grt. (150 d) is allied to *varia* and, at the same time, forms the transition to the next group; it differs from *varia* in the entire absence of the white subapical blotch, the postmedian line extending much more irregularly, and a distinct median line forming a sharp, almost right angle distally above the inner margin; the submarginal line is broken up into single internerval streaks, and the marginal line is fine, black. Hindwing of a pure white, with a small black anal spot and somewhat smoky costal margin. Cuba and Florida.
- daona.* **D. daona** Drc. (= *androdora* Dyar) (150 d) as well as the two following species are probably hardly separable specifically from *cubana*; according to DYAR it merely differs in the postmedian line being less dark and more faded. Forewing light whitish-grey, lightest in the median area, densely dusted with brownish-grey; the rather indistinct double antemedian line extends deep black above the inner margin as an arcuate line back almost to the base; behind the fine black discal lunular streak there is a greyish-black lunular spot filled with yellowish-white below, traversed by long fine black internerval streaks and bordered below by a jet-black arcuate line; this large dark spot is almost obsolete in the apparently rare ♂. Hindwing white, slightly scaled, smoky at the costal margin, with a small anal blotch. Mexico. — f. n. **suavis** (150 d) I denominate a distinctly separable constant race from Colima, which is smaller and of a much softer bluish-grey colouring, intensely mixed with rust-brown basally and postmedianly, especially in the surroundings of the transverse lines; the ultracellular lunular spot is not filled with yellowish-white below, but with rust-brown; all the black lines are much finer.
- clitiusa.* **D. clitiusa** Schs. is very similar to *daona*, but larger and much lighter, the subterminal line less distinct and the line above vein 2 straighter. Ground-colour light sand-coloured, partly mixed with reddish-brown, the lines otherwise as in *daona*; the feeble whitish subterminal line is bordered with black inside between 8 and 6 and has a small black spot above 3. Hindwing white, costal margin sand-coloured, with 3 dark apical lines, the inner margin also light brownish-grey. Expanse of wings: 45 mm. Brazil (Joinville).
- aroensis.* **D. aroensis** Schs. Forewing grey, with a yellowish tinge at the inner margin and distal margin and below the median vein, with fine black-striped veins and single internerval stripes; transverse line and median line rather indistinct, the latter undulate, the posterior transverse line only irregularly marked by single black scales, grey shading behind the cell and subapically. The ♀ is of a purer silvery grey without the yellowish tinge, without transverse lines and subterminally more intensely dusted with brown. Hindwing white, smoky at the costal and inner margins, darkened in the ♀ with a brownish-grey margin. Expanse of wings: ♂ 38, ♀ 46 mm. Venezuela.
- gelduba.* **D. gelduba** Schs. (150 d) is allied to the preceding species, but it has shorter broader forewings; it is wrong to range it under *Rifargia*, for the apparently rare ♂ seems not yet to have been known hitherto; it is, however, before me and has shortly pectinated antennae; forewing brownish-grey, intensely mixed with olive green, with a fine black basal ray, indistinct single transverse lines more or less distinctly bordered with red-brown, and a discal crescentiform streak, before which a brown arcuate shadow extends to the margin above the anal angle; blackish-grey marginal shading in the upper half of the wing extends in an acute angle on the lowest radial branch to the cross-vein and contains 4 jet-black oblique internerval streaks subapically. Hindwing white, slightly smoky at the costal and inner margins, brownish-grey in the ♀. The ♂ is without the brown arcuate shadow to the anal angle, the subapical marginal shading is very indistinct. Mexico.

D. captiosa *sp. n.* (150 d) is very similar to *gelduba*, but surely different. Forewing blackish-grey, *captiosa*. whitish in the median area, without any olive tint, dusted with red-brown behind the cell and narrowly at the margin, also near the single blackish transverse lines; marked like *gelduba*, but it exhibits a very much thicker black subterminal shadow extending arcuately between the median nervules to the lower cell-angle, and the subapical internerval streaks are much stronger and extend to the margin; the marginal line itself, being undulate in *gelduba*, is rectilinear here and double, the interior portion thicker than the exterior one. Hindwing blackish-grey, lighter towards the base, fringe speckled darker, unicoloured in *gelduba*. Mexico (Zacualpan, Cuernavaca). Type ♀ in the Coll. DRAUDT.

D. semilunata *Schs.* (150 e) is somewhat similar to the preceding species, but at once discernible by *semilunata*. the entirely white hindwings. Forewing light grey, dusted with reddish-brown at the base, with fine black basal and inner-marginal rays; the crescentiform shadow from the lower cell-end to the anal angle is deep velvety brown; 3 dark postmedian transverse lines are partly confluent and form a dark shadow above the lunular spot. Undulate line white. Expanse of wings: 33 mm. Brazil (Castro, Parana).

D. peruviansis *Dogn.* is presumably the Peruvian representative of *daona* and *aroensis*. Forewing *peruviansis*. steel-grey, whitish and mixed with reddish-brown at the costal margin, white in the cell, with black basal rays as far as the double antemedian line; a red-brown subterminal shadow extends from the fine black arcuate streak between the median nervules to the costal margin, traversed by black internerval streaks, bordered with white above. Hindwing purely white with a small black anal spot and costal margin. Expanse of wings: 43 mm.

D. epimacha *Schs.* Head and thorax light reddish-yellow mixed with red-brown, abdomen brownish *epimacha*. sand-coloured above. Forewing brown towards the base, the base itself grey, bordered by a double black line proceeding from a small orange spot at the base of the median vein; filled with white; the anterior transverse line is fine black, oblique to the inner margin, where it meets the fine median line; behind the blackish-brown postmedian line, between the subcosta and vein 3, there is a large reddish-yellowish white area, shaded with brown at the costal margin, outside by the red-brown subterminal shadow entering between 6 and 4 and turning velvety blackish-brown below 4; the light area is crossed inside by a curved fine red-brown line, outside by a double similar one filled with white; yellow internerval spots are at the margin, shaded with brown inwards; vein 1 and the cellular nervules are partly strewn with black and white. Hindwing dark reddish-brown with a feeble lighter postmedian line ending in a white spot at the anal angle. Expanse of wings: 43 mm. Cayuga (Guatemala).

D. multilineata *Dogn.* reminds us of *aroensis*, forewing greenish mixed with reddish-grey, dusted *multilineata*. with lilae subcostally and at the distal margin, double very fine sharply angled antemedian and median transverse lines, and 4 strongly dentate indistinct postmedian transverse lines which are twice interrupted by longitudinal streaks; the subterminal line is irregular. Hindwing diaphanous white, with yellowish hair at the inner margin. Expanse of wings: 37 mm. Argentina.

D. amanda *B. & Linds.* is nearer to *varia* owing to the shape of the subterminal line; forewing grey, *amanda*. dusted with white at the costal margin, somewhat lighter and with a reddish-brown tint basally, above the inner margin and behind the cell; transverse lines double, the anterior one oblique to the centre of the inner margin, filled with a lighter colour, with distal curves between the veins, the posterior one with the reverse curves, more vertical, distally concave behind the cell, projecting quadrangularly behind the lower cell-end; subterminal line as in *varia*, distally accompanied by a feeble whitish line; the cell-end streak is a fine curved black line. Hindwing white, costal and distal margins dusted with greyish-brown, darker greyish-brown in the ♀ with a lighter postmedian band. Arizona.

D. manteo *Dbld.* (= *eineraseens* *Wkr.*, *subalbicans* *Grt.*) (150 e) represents an entirely different type; *manteo*. forewing whitish ash-grey, dusted darker, with 2 double, very dentate transverse lines, a strong black cell-end streak which is mostly broken up into two dots above each other in somewhat lighter surroundings; the costal-marginal part of the postmedian line is mostly situated in a darker dusted spot which may be very large; undulate line shadow-like darker, somewhat dentate, black dots at the margin. Hindwing dark smoky grey with a feeble lighter postmedian line and a dark anal spot. — The larva is green with broad yellow subdorsal lines and narrow lateral lines, the former more separated on several segments, and dorsally filled more or less red. It chiefly lives on oaks, and may be so common that it is destructive to them, but it occurs also on various other deciduous trees. In the Eastern United States from Canada to Texas.

D. rascona *Schs.* (150 e) is very similar to *manteo*, but it has been ranged under *Rifargia* of late; the *rascona*. ♂ not being at hand I cannot decide this question. Darker blackish-grey than *manteo*, much lighter whitish-grey subterminally, lightest above the anal angle; the marking is quite the same, though the transverse lines are less distinct, extinct in the dark ground-colour, black and white vein-dots behind the postmedian line, a whitish line behind the undulate line. Hindwing darker brownish-grey. Mexico.

D. externa *Wkr.* (= *spurca* *Schs.*) (150 e) is like *rascona* in colour and marking, forewing lighter *externa*. ash-grey, less strewn, without the whitish-grey subterminal brightening, only somewhat lighter above the

anal angle; a large blackish triangular spot in and behind the median area in the costal half; undulate line not at all prominent in the grey ground-colour. Fringe distinctly speckled grey and black. Hindwing light grey, a black spot divided by white is at the anal angle. Colombia.

nigriplaga.

D. nigriplaga Jones. Forewing yellowish ochre, strewn with olive brown and black, with a black cell-end spot and double dark transverse lines, a small white costal-marginal spot behind the distal line, and a large triangular dark costal-marginal spot extending to the apex and downwards to the lowest radial branch, with 2 black internerval streaks in it; undulate line composed of a series of faded olive spots; a large black spot at the base below the cell. Hindwing yellowish, the veins, costal and distal margins strewn with brown, with a light brown double faded postmedian line. Expanse of wings: 38 mm. Brazil (Castro, Parana).

contracta.

D. contracta Wkr. has light grey forewings strewn with brown, with single interrupted transverse lines nearing each other below the median vein, so that the darker dusted median area assumes the shape of a sand-glass; two black dots in the cell-end are above each other, in somewhat lighter rings and with darker shading before and behind them; a large brown triangular spot in the basal part below the cell, a light undulate subterminal line is shaded with black inwards and followed anally by two thick black spots; black lunular subterminal streaks; fringe speckled light and dark. Hindwing brownish-grey, darkened at the margin, fringe light. Brazil.

divisa.

D. divisa Schs. The larger basal half of the forewing is dark slate-coloured as far as the reddish-brown median line, traversed by quite obsolete lighter transverse lines, with a light grey spot behind the red-brown basal line; the distal part is light brown, darkened at the cell-end; postmedian line darker brown, shadowy, double, a series of black spots before the light undulate line, small dark spots also at the ends of the veins. Hindwing whitish, brownish on the veins and margin, with a double dark anal spot. Expanse of wings: 49 mm. Brazil (Rio de Janeiro).

cervina.

D. cervina Mschlr. has light reddish-brown forewings strewn with blackish and red-brown shading before the yellowish notched undulate line; both the transverse lines are indistinctly double, darker red-brown, black and white dots are on the veins behind the distal line; a large reniform orange macula at the cell-end is centred reddish and finely surrounded with black, 2 red-brown successive dots before it in the cell; the veins of the marginal area are blackened and strewn with white, 2 black dots each are between them. Hindwing whitish, slightly shaded reddish-brown at the margin. Guiana. It has remained unknown to me.

sylvia.

D. sylvia Schs. has white forewings strewn with grey and olive, with an irregular median shadow angled at the cell-end, and dark grey spots in the base of the cell and below it; instead of the postmedian line a double row of black vein-dots, partly shaded with olive; a darker spot before the apex at the costal margin, and a feeble grey subterminal shadow below it, black vein-streaks on the margin. Hindwing whitish, shaded with blackish at the apex and distal margin. Brazil (Castro, Parana).

isidra.

D. isidra Schs. (150 e). The white forewing is widely strewn with black and brownish orange scales, with interrupted traces of black transverse and median lines, the posterior one double, partly scaled orange; a black crescentiform streak at the cell-end, black wedges of the undulate line before the margin, marginal streaks behind them between the veins. Hindwing densely strewn with blackish-brown, with traces of a white postmedian line. Mexico.

spectra.

D. spectra Schs. is closely allied to *isidra*, distinguished by the abdomen being yellowish ochreous — grey in *isidra* — and lighter greyish-brown hindwings; it is somewhat larger. Expanse of wings: 47 mm. Costa Rica.

eusebia.

D. eusebia Drc. is a very much larger species with greyish-brown forewings, the fine black transverse lines are double, notched, the two anterior ones near the base, the third behind the cell; a red-brown spot bordered with black is at the cell-end; the subterminal line is light reddish-yellow, a marginal row of black dots behind it, fringe brown. Hindwing brown, lighter towards the base and at the inner margin, with a small black anal spot parted by white. Expanse of wings: 64 mm. Described from Colombia.

tuna.

D. tuna Schs. has somewhat longer and more slender palpi and narrower forewings than the other species of the genus; forewing light reddish-yellow in the basal half and postmedianly, with a dark-striped median vein, strewn with brown below it; distal half strewn with reddish-brown, with a black subcostal stripe ending in a black subapical spot; the double postmedian line is marked brown with interruptions, the black undulate subterminal line is shaded spot-like above the anal angle. Hindwing greyish-brown. Expanse of wings: 35 mm. Colombia.

patricia.

D. patricia Schs. has light grey forewings with a velvety black oblique streak from the base of the costa to the submedian vein at the undulate anterior transverse line, and a white lunular spot bordered with brown

at the cell-end, with a whitish brightening behind it; the velvety black postmedian line is bent inwards to the cell, reaching neither the costal margin nor the inner margin, followed behind it by a broad brown black-strewn shadow; the grey distal margin is parted by a brown line, marginal line black. Hindwing white with a dark marginal line and strewn with dark at the anal angle. Expanse of wings: 40 mm. French Guiana.

D. staria Schs. Forewing steel-grey in the cell and in the white basal area with reddish-brown transverse stripes, the double black anterior transverse line is partly filled with reddish-brown; a dark streak bordered with white inside is at the cell-end, a red-brown spot above it, similar dusting behind and below the cell-end; a large grey shadow behind the double postmedian line, which is filled with red-brown, extends down to the lowest radial branch, a white spot extends from it to the upper median branch; marginal area whitish, strewn with red-brown, most densely at the apex and anal angle, the white veins densely strewn with black at the ends. Hindwing brownish-grey with a black interrupted marginal line and white, dark-speckled fringe. Expanse of wings: 45 mm. Guatemala.

D. hertha Schs. is a large species with light brown forewings strewn with grey at the base, costal and inner margins, with a dark transverse line through the centre, and a treble dentate postmedian line; steel-grey behind it as far as the black submarginal line, with black internerval streaks bordered with brown outside; distal margin light brown. Hindwing brown. Expanse of wings: 50 mm. Brazil (Petropolis).

D. atrax Schs. is still larger than *hertha*, forewing blackish-grey, lighter basally, with light grey submarginal shadows; the black transverse lines are very indistinct in the dark ground; fringe speckled black. Hindwing white with a narrow dark grey distal margin and dark hair at the inner margin, with the beginnings of dark grey transverse lines at the costal margin. Body dark grey, only the base and end of the abdomen are red-brown. Expanse of wings: 52 mm. Brazil (Rio de Janeiro, Corcovado).

D. dolorosa Schs. (150 f) is closely allied to *atrax*, but the basal costal-marginal half is filled with white excepting the inner margin, the black dentate transverse lines are better visible, the posterior line double, filled with light grey; a black dot in the cell, a brown lunular streak at the end; the distal white border of the dentate subterminal line is confluent with white marginal spots above the anal angle. Hindwing similar to that of *atrax*. Mexico to Costa Rica.

D. nebulosa Dogn. is similar to *dolorosa*. Forewing lilac brown, darkest at the inner margin, mixed with white towards the margin, with a large white, brown-strewn spot in the basal costal-marginal half and a similar curved stripe from the centre of the median vein to the inner margin before the anal angle; two brown lunular streaks at the cross-vein are filled with white, the double black posterior transverse line is interrupted; fringe speckled white and brown. Hindwing brownish-grey with darker veins. Expanse of wings: 45 mm. French Guiana.

D. elongata Drc. is also allied to the preceding species; forewing dark grey, white in the basal costal-marginal half, with a large reddish-brown spot near the apex and distinct black transverse lines only in the inner-marginal half; fringe dark grey. Hindwing purely white. Expanse of wings: 50 mm. Described from Peru.

D. camilla Dogn. Forewing light olive grey with fine black transverse lines, the subbasal line submedianly connected with the anterior transverse line in an X-like way, the posterior line treble, strongly dentate, undulate line double, distally accompanied by a white line; black dusting enclosing a triangular black dot is in the centre of the inner margin between the transverse lines; fringe speckled black. Hindwing white, the costal and inner margins as well as the veins dusted with olive. Expanse of wings: 42 mm. Amazons (Sao Paulo de Olivença).

D. otiosa Schs. Forewing brownish-grey, lighter towards the base, with a whitish area at the distal margin; being broadest between the median nervules, and strewn with reddish-brown, with fine brown double transverse lines and a black marginal line which is undulated analwards; fringe speckled dark. Hindwing white with a dark brown marginal line and yellowish inner-marginal hair. Expanse of wings: 40 mm. French Guiana.

D. tharis Stoll (= *laeca* Schs.) (150 f) is a common well-known species with red-brown forewings, greyish-white at the inner and distal margins, two brown small spots at the distal margin and a large greyish-white round cell-end spot, 3 small costal-marginal spots above it, and 2 small white spots obliquely below it; the brown ground is traversed by numerous dentate transverse lines, the posterior one punctiform, the lines partly light brown also visible on the white ground. Hindwing brownish-grey, a white anal spot parted by blackish-brown at the anal angle, fringe white. From Mexico to Peru and Brazil. — *livescens* f. nov. (150 f) I denominate a somewhat smaller form which is before me from Novo Friburgo and in which the greyish-white parts are darker bluish-grey, the brown colour of the wings mixed with rusty yellow in some places, especially basally and between and behind the cell-end maculae.

D. aemula Schs. (150 f) is similar to *tharis*, somewhat smaller, the brown colour prevailing on the forewing so that only a narrow stripe along the inner margin remains greyish-white; the transverse lines crossing it are very distinct; the white dots of the postmedian line are situate in the brown ground, the brown marginal markings are also augmented. Hindwing as in *laeca*. Guiana, Brazil.

- sabaria*. **D. sabaria** Schs. Basal area of forewing obliquely from the costal margin to the centre of the inner margin dark brown as far as a black median streak, behind it white strewn with yellowish rust-colour; a double median line is cinnamon-brown, extending from the centre of the costal margin to behind the centre of the inner margin and filled with white, strewn with black in the cell; a small black spot at the cell-end; distal area broad brown, darker at the apex, shaded with brown between 4 + 5 and 3 and the submedian fold; the indistinct cinnamon-brown postmedian line is far outside. Subterminal line fine light, widened below 5 and white; cellular veins black, fringe white, speckled black on the ends of the veins. Hindwing brown with a double dark postmedian line, a feeble lighter band behind it. Expanse of wings: 50 mm. French Guiana.
- hyginia*. **D. hyginia** Schs. differs much from the other species. Forewing brown with an olive tint, the fresh insect presumably brighter green with a large white triangular area from the base to the centre of the costal margin to vein 1 before the centre of the inner margin, with fine rusty brown double transverse lines; a blackish-brown spot at the cell-end, a curved red-brown line behind it; blackish-brown strewing between the median and posterior transverse lines between vein 2 and the submedian fold; white, brown-scaled spots in the lower marginal half. Hindwing white, thinly scaled in the disc, brownish at the inner margin, white at the costal margin, with a double postmedian line and a small apical spot. Expanse of wings: 46 mm. Brazil (Rio Purus).
- plebeia*. **D. plebeia** Schs. Forewing brown with finely dentate double transverse lines, the posterior one indistinct, followed behind the cell by a quadrangular dark brown spot and dark brown shadows above it and towards the inner margin; the upper half of the antemedian area dark brown, Isabel-coloured below the cell and at the base of the inner margin, the undulate line of the same colour; a dark brown spot also at the cell-end, followed by an oblique shadow which is angled at the lower cell-end. Hindwing brown with an indistinct lighter postmedian shadow. Expanse of wings: 38 mm. Costa Rica.
- cariosa*. **D. cariosa** Schs. has light brown forewings, the distal half of the costal margin and the base of the inner margin being the lightest parts, with an oblique blackish shadow from the costal margin to the centre of the inner margin and a similar postmedian shadow in the lower two thirds; a red-brown line at the cross-vein, one dot each below it and above it; the brown posterior transverse line is double, shaded with black and grey in the lower half. Hindwing brown, spotted black and light anally. Expanse of wings: 30 mm. British Guiana.
- santiago*. **D. santiago** Schs. is steel-grey on the forewing, the anterior half of the median area whitish, with fine double transverse lines, the distal part of the anterior line black, the interior part lighter, olive, and olive dusting extends from it below the cell towards the base; the whitish anterior half of the median area is distally formed by a black median line with two arches; reddish-brown and olive shading behind the postmedian line, the distal margin behind the red-brown subterminal line is olive with a black marginal line. Hindwing white, costal, distal and inner margins brown. Cuba (Santiago).
- notabilis*. **D. notabilis** Schs. (= *normula* Dogn., *hemicera* Schs.) (150 g). Forewing grey with a large brown oblique area extending from the upper half of the distal margin broadly into the inner margin, with a black cell-end dot; instead of the posterior line there are black and white vein-dots. Hindwing violettish-brown, darkened at the distal margin, with yellowish inner-marginal hair. Guiana, Colombia, Bolivia, Peru, Costa Rica.
- ligneata*. **D. ligneata** Wkr. (= *aconthea* Drc.) (150 g) together with *notabilis* and the two following species forms a group of closely allied forms. Forewing brown, striped darker on the veins, lighter in the spaces between them, without distinct transverse lines.
- puseyae*. **D. puseyae** Dyar (150 g) is similar to *ligneata*; forewing light brown, shaded with dark brown along the basal half of the costal margin and below and behind the cell, distally bordered by the light subterminal shadow; the light, strongly notched single transverse lines are very indistinctly marked by light dots on the veins, the most distinctly in the narrow deep dark brown inner margin; 2 small dots above each other at the cell-end. Hindwing brown, somewhat yellowish in the disc. Peru, Bolivia.
- mephitis*. **D. mephitis** Schs. (150 g) is very much like *puseyae*, easily distinguished by the much thicker discal dots the lower one of which is by far the largest; they are usually confluent in the ♀; the posterior transverse line is more distinctly marked by black double dots filled with yellowish-white. Mexico.
- echina*. **D. echina** Schs. (150 h). Forewing reddish brown, broadly moss-green at the costal margin, moss-green strewing at the distal margin and below the lower cell-end, the fine dentate black transverse lines rather indistinct, white vein-dots behind the distal line; darker strewing in and below the cell, red-brown shading at the base of the inner margin and behind the cell, an irregular marginal shadow is also reddish-brown, darkest analwards; dark streaks at the ends of the veins are followed by light dots, fringe speckled. Hindwing dark brown, thinly scaled with a darker apical shadow divided by reddish-brown. Expanse of wings: 37 mm. Guiana, Colombia.

D. vestona Schs. (= *proba* Schs.) (150 h) has dark moss-green, black-strewn forewings with very *vestona*. indistinct double darker transverse lines and a fine cell-end streak surrounded by a lighter green colour; white vein-dots on both sides of the postmedian line; a subterminal row of small blackish-brown spots. Hindwing greyish-brown with a dark marginal line dotted yellow on the ends of the veins. Mexico.

D. dardania Drc. (150 h) is very similar, but more or less mixed with red-brown, the double transverse *dardania*. lines more distinct, filled with reddish-brown, the veins strewn black and white; the posterior transverse line ends at the inner margin with a small white angular spot. Hindwing greyish-brown, lighter in the disc, with 2 dentate darker postmedian lines. Mexico.

D. arima Schs. is very near to *vestona*; distinguished by quite different hindwings which are broadly *arima*. brownish-grey at the inner margin and distal margin, whitish in the lower half of the cell and behind it, brownish olive at the costal margin, with a double postmedian line and black subterminal line, the postmedian line continued by dots. Forewing brownish olive, strewn with black, the dentate lines similar to those of *vestona*, indistinct, a fine black line bordered with reddish-brown is at the cross-vein; white vein-dots behind the postmedian line and subterminal blackish and reddish-brown internerval streaks; a dark stripe strewn with reddish orange before the centre of the inner margin. Expanse of wings: 40 mm. Brazil (Rio Purus).

D. psalmoida Schs. is a very small species; body dull green. Forewing reddish olive with fine blackish- *psalmoida*. brown transverse lines, the subbasal line double at the costal margin, a fine line at the cross-vein, the postmedian line distally bordered with white at the costal margin, undulate, dentate from 5 to the inner margin, followed by black and white vein-dots which are connected by a very fine undulate line; cellular branches black as far as the margin. Hindwing white, reddish-brown at the inner margin, the costal margin broad reddish olive with the beginnings of dark lines, white subterminally between. Expanse of wings: 29 mm. Venezuela.

D. biundata Wkr. (= *olivata* Pack., *sempiaga* Wkr., *viridescens* Wkr., *mollis* Wkr.) (150 h) is an *biundata*. extremely common and widely distributed species with dull olive green forewings, the single dark brown dentate transverse lines bordered with reddish-brown on both sides, a similar cell-end streak below which there is a more or less distinct spot of blackish dusting; red-brown subterminal wedges, edged with yellowish-white especially towards the apex, and whitish vein-dots before the redbrown-spotted fringe. Hindwing greyish-brown with an indistinct lighter almost straight postmedian line which begins distinctly dentate in the darkened costal-marginal part. North America (Atlantic States) to Brazil and Peru. — Larva thickened in the middle, green with a broad white dorsal band which is strangulated between the 6th and 7th segments and separates behind into the white long caudal points, whilst it is spotted brown laterally especially on the middle segments; head red-brown. It lives on a great number of deciduous trees.

D. subguttata Wkr. Forewing brownish olive, strewn darker brown, and instead of the transverse *subguttata* lines with double rows of blackish spots between the veins; the anterior ones indistinct, the posterior ones more distinct and irregular, the spots between the median nervules and the subapical ones thicker than the others, those between the lower radial branches removed inwards; a round blackish spot in the cell and at its end; undulate line lighter, shaded dark inwards, black streaks before the margin. Hindwing brownish-grey, with brownish hair at the inner margin. Brazil.

D. guttivitta Wkr. (= *albiplaga* Wkr., *meorea* Herr.-Schäff., *einereus* Pack., *harrisi* Pack., *indeter-* *guttivitta*. *minata* Wkr., *doubledayi* Scddr.) (150 h) is very similar to *subguttata*, and very difficult to distinguish in worn specimens. The last joint of the palpus is decidedly shorter, the 2nd joint has outside only a narrow black streak, whilst it is almost entirely black in *biundata*; the slightly curved discal streak is situated in a large light ash-grey halo, the transverse lines are less distinct, and the olive-green colour is mostly not so uniform; on an average, the species is somewhat smaller than *subguttata*. — Larva very different, head green like the body with a red arcuate streak bordered with yellow on each hemisphere; the dorsum exhibits a white line which is treble before and behind the middle, and yellow subdorsal lines, the former line being bordered with red on the 3 first segments, spotted red-brown on the 6th, 9th and 10th segments; smaller red-brown spots on the sides of the 3rd, 9th and 10th segments above the feet. It chiefly lives on maple, but also on oak and apple; chestnuts, beeches and snowball. Atlantic States.

D. virgea Schs. is likewise very similar to *biundata*, and presumably the southern representative; *virgea*. forewing brighter dark olive green, the dark brown transverse lines bordered with a lighter brown, the curved cell-end streak in a light brown halo; the brown submarginal wedges larger, more coherent and very broadly bordered with yellowish especially apically. Hindwing light grey, with yellowish hair at the inner margin; thickly dusted with black at the distal margin. The species is larger. Expanse of wings: 44 mm. Brazil (Petropolis).

D. vivida Schs. is very closely allied to the preceding species, forewing bright green, the brown *vivida*. transverse lines shaded with reddish-yellow and brown, similarly shaped as in *biundata*, the posterior line almost straight to the inner margin; the discal streak is in a large whitish spot; the brown subterminal spots are bordered with whitish, pointedly dentate basally in the upper quarter; white dots on the margin, fringe as

well as mesothorax brown. Hindwing whitish, with darker veins, green at the costal margin with the beginning of a white postmedian line, smoky at the margin, almost quite greyish-brown in the ♀. Expanse of wings: ♂ 46, ♀ 53 mm. A large species from Costa Rica.

muscosa. **D. muscosa** *Mschlr.* is marked like *biundata*, but the ground-colour is a lighter moss-green and the transverse markings are darker green without any yellowish and red-brown tints; the median area is somewhat more intensely strewn with blackish than the rest of the wing, somewhat more intense shading only before the undulate line; a blackish crescentiform streak at the cell-end, the green ground of the wing behind it still somewhat lighter, only the veins being darker. Hindwing very much lighter grey, fringe speckled light and dark green. Expanse of wings: 45 mm. Guiana.

mullinsi. **D. mullinsi** *Schs.* Forewing dark green with a large brown area behind the cell as far as the brown subterminal shadow, a short white inner-marginal streak before the latter, with fine black transverse lines. Hindwing white, reddish-yellow at the inner margin, broadly brown at the costal margin with the beginnings of a dark and light transverse stripe. The margin of the ♀ is broadly darkened. Expanse of wings: ♂ 46, ♀ 60 mm. Costa Rica.

disciplaga. **D. disciplaga** *sp. n.* (150 h) is deep olive green on the forewing, the dark brown, undulate dentate transverse lines are bordered with a lighter reddish-brown on both sides; a similarly coloured reniform macula at the cell-end, the space behind it and below it strewn with blackish, quite black between 2 and 4, distally bordered by two deep velvety black lunules; small red-brown, darker-centred internodal spots subterminally; fringe almost black. Hindwing brown with a straight light postmedian line from before the apex to the anal angle. According to 1 ♂ from West Colombia (Rio Micay) in the Coll. NIEPOLT.

antistes. **D. antistes** *Schs.* is similar to *disciplaga*, dull green, shaded with violettish-brown at the base of the inner margin, with a blackish-brown inner-marginal stripe; the fine double transverse lines are very indistinct, an oblique blackish-brown shadow behind and below the cell-end as far as the postmedian line, this line with a white inner-marginal spot and white vein-dots behind it; the space behind the cell is lilac brown with green veins; small feebly brown subterminal spots, white dots at the ends of the veins. Hindwing blackish-brown with white dots on the ends of the veins. Expanse of wings: 44 mm. Costa Rica.

delira. **D. delira** *Schs.* The brown transverse lines on the moss-green forewing are bordered with rosy red, the green cross-vein is bordered with pink on both sides; a submarginal irregular row of pink spots shaded with brown and bordered with black inwards; fringe grey mixed with brown behind the dark marginal line. Expanse of wings: 31 mm. A smaller species from French Guiana.

lopodites. **D. lopodites** *Dyar* is very similar to *vestona*, but much less green, more blackish-brown, green only at the costal margin, the interior transverse line filled with white, before it at the inner margin there is an ochreous longitudinal blotch bordered with black below; the double posterior transverse line is reddish-brown, filled with white at the inner margin; the subterminal spots are black. Hindwing greyish-brown, darker at the costal margin with the beginning of a light postdiscal line. Expanse of wings: 33—37 mm. Panama, Costa Rica.

bochica. **D. bochica** *Schs.* is likewise allied to *vestona*, but almost without any green or altogether without it, darkened blackish-brown before the antemedian line and in and behind the cell-end, the velvety black discal streak surrounded by light brown; transverse lines double, white vein-dots behind the distal line, and a short white line at the inner margin; as in *lopodites* the veins in the marginal area are black, strewn with white and terminate before the fringe with white dots. Hindwing brownish-grey, whitish-grey in the disc, light brown at the costal margin, enclosing a dark subterminal line distally bordered with white. Expanse of wings: 31 mm. Guatemala.

editha. **D. editha** *Schs.* Forewing light green, violettish-brown in the basal third, mixed with black and green and distally bordered by a double red-brown line, the distal line darker; a fine dentate median shadow is interrupted at the cell-end by a light reddish-yellow spot in which there are 2 dark dots on the cross-vein; a grey shadow from the lower cell-end to the inner angle, postmedian line red-brown, partly double; a fine undulate-linear shadow is interrupted in the lower half, forming 2 spots above the anal angle and followed in the upper half by a darker greyish-black shadow. Hindwing yellowish-white, shaded with reddish-brown on the veins and margin, with a feeble postmedian line and small anal spots. The much larger ♀ has a more distinct postmedian line on the hindwing and a broader red-brown distal margin. Expanse of wings: ♂ 44, ♀ 59 mm. Costa Rica.

manethusa. **D. manethusa** *Drc.* (150 i) is not dissimilar, but much paler on the whole, reddish-brown in the basal third, almost white outside, light greenish in the marginal area excepting the apex, transverse lines broken up into black and white vein-dots. Hindwing greyish-white, darkened apically. Head and thorax greenish-yellow, strewn with a darker colour. Costa Rica.

albovirens. **D. albovirens** *Dogn.* (150 i) is closely allied to *manethusa*; forewing light yellowish-green, mixed with moss-green and brown, darkest in the basal third and in the distal half of the costal margin, traversed by a broad purely white oblique band from the first quarter of the costal margin to the anal angle; transverse

lines only distinct in their beginnings at the costal margin, behind which they vanish in the variegatedly strewn ground of the wing; fringe greenish, speckled black. Hindwing white with greenish margins. Expanse of wings: 37—39 mm. Peru.

D. tricolor *Drc.* is likewise similar, forewing yellowish-white, greenish mixed with brown in the basal third, greenish-brown on the body. Hindwing all white, strewn with green only at the costal margin. Expanse of wings: 45 mm. Colombia.

D. gilboa *Drc.* is also similar. Forewing white, greenish-brown in the basal third, thickly strewn with white, with a greenish-brown postmedian oblique band which is broadest at the costal margin, quite narrow analwards; apex and distal margin dusted with green. Hindwing white, costal margin and fringe greenish. Expanse of wings: 45 mm. South-Eastern Peru.

D. subalbida *Schs.* Forewing green, grey in the basal third, bordered by a darker double line; the fine posterior transverse line is also dark grey, the distal-marginal area dusted with grey with a small whitish spot at the inner margin behind the postmedian line. Hindwing whitish, green at the costal margin, dark grey at the inner margin, with a dark postmedian line which is only distinct at the costal and inner margins, a dark green marginal line and green fringe. Expanse of wings: 37 mm. Brazil (Castro, Parana).

D. infanda *Schs.* (150 i). Forewing almost black in the basal third, strewn with green at the inner margin; the cell is green, whitish towards the end, strewn with red-brown, otherwise green, with a lilac area below the lower cell-end and a black oblique blotch at the base of vein 2; posterior transverse line double, red-brown; small black subterminal spots bordered with grey outside are in the upper half and above the anal angle; distal margin and fringe light green, fringe speckled darker. Hindwing whitish, strewn with blackish at the distal margin, with a small black anal spot and yellowish and reddish inner-marginal hair. Expanse of wings: 39 mm. French Guiana.

D. meretricia *Schs.* (150 i). Forewing light green, dark olive green in the basal third, bordered by the almost straight anterior transverse line; a large yellowish-reddish spot at the cell-end encloses 2 small brown spots, the dentate postmedian line is blackish-brown, double, beginning as a dark costal-marginal shadow; subterminal spots black, removed inwards between the radial branches, fringe speckled black on the ends of the veins. Hindwing pink with a blackish-brown distal margin and postmedian line, fringe green. Costa Rica.

D. tumacona *sp. n.* (150 i) is very closely allied to *meretricia*. Forewing uniformly moss-green, basal area deep black in the costal half, dusted with red-brown below it, distally bordered by the very fine antemedian line; a red-brown spot below the cell-end between 2 and 3, a line above this spot extends to the costal margin; the very fine red-brown postmedian line is only visible in the costal half and at the inner margin: behind it at the costal margin there is a steel-black triangular spot warming into red-brown at the costal margin with the beginnings of 3 or 4 light lines; a black subapical spot, a subterminal black dot only above 3 and one at the anal angle; fringe green with black vein-dots. Hindwing brownish-pink, lighter yellowish-white in the disc, a small black spot at the anal angle, costal margin brownish-grey with the beginnings of light and dark lines; fringe moss-green. 2 ♂♂ from West Colombia (Rio Tumaco) in the Berlin Museum.

D. bactrea *Schs.* (= *erocea* *Dogn.*) (150 i). Forewing green, violettish-brown in the basal third, strewn with black and green, distally bordered by the irregular double black anterior transverse line, a black and grey spot in the cell behind it; discal streak red-brown, surrounded with reddish-yellow, a blackish spot below the distal cell-end; median line interrupted, blackish, the posterior transverse line double, red-brown, shaded with black at the costal margin, inner margin and behind the cell; small black submarginal double spots connected by lilac grey; fringe reddish-brown, speckled black. Hindwing pinkish-brown, dusted with black at the distal margin, most densely so at the apex and anal angle, with a dark postmedian line. Expanse of wings: 33 mm. French Guiana.

D. praestana *Dogn.* is allied with *bactrea* and *viridiana*: forewing green, shaded darker at the base, bordered by a black double line, a dark median shadow extends through the cross-vein; the same double submarginal spots filled with whitish are behind the dark green postmedian line; hindwing pink, darkened greenish at the distal margin and costal margin, the latter with the beginnings of 3 darker lines. Expanse of wings: 40 mm. Ecuador.

D. viridiana *Jones* is very similar, yellowish-green, darkened brown at the base, the double antemedian line filled with brown and almost straight, curved in *praestana*, the postmedian line which is only double in the upper third is followed by a light brown shadow; the submarginal spots are the same. Hindwing yellowish ochre, with a pink hue in the disc, dusted with green at the costal and distal margins, with a broad brown marginal band. The ♀ has quite dark red hindwings. Expanse of wings: ♂ 38, ♀ 47 mm. Brazil (Castro).

D. marginalis *Schs.* Forewing light violettish-brown, green at the base of the costal margin and in the cell, also along the inner-marginal vein and in the space between the median nervules and subterminally, the latter area distally bordered by a curved brown line which is broadly bordered with white inside and extends

from the apex to the upper median nervule; distal margin blackish with green internerval spots, a black spot at the anal angle; transverse lines dark brown, with traces of dents. Hindwing blackish-brown. Expanse of wings: 36 mm. French Guiana.

surinamensis. **D. surinamensis** *Mschlr.* has red-brown forewings, dusted with olive green at the costal margin, in the cell, subterminally, and narrowly at the inner margin; both the transverse lines single, the posterior one dentate, the anterior one only curved; black and white dots behind the distal line on the veins; a large greenish-white reniform macula at the cell-end is centred brown and finely surrounded with black; the undulate line replaced by scalariform black streaks and black double dots above each other before the margin. Hindwing brown, fringe yellowish-white. Surinam.

princeps. **D. princeps** *Schs.* is a larger species with yellowish-green forewings, with a dark oblique shadow from the base of the cell to the inner margin which is confluent here with the fine antemedian line; a dark green oblique shadow extends from the centre of the costal margin almost to the anal angle, greenish-white postmedian vein-spots are between small dark spots; a dark veined shadow is subterminal. Hindwing yellowish-white. Expanse of wings: 45 mm. Costa Rica.

paranensis. **D. paranensis** *Schs.* (150 k). Forewing greyish-white, the first two thirds of the costal margin and the base of the inner margin darker grey, with a green oblique shadow from the base of the costal margin to the centre of the inner margin and the anal angle; distal margin greenish with black ends of the veins. The apical third of the costal margin is broadly bluish-green, double transverse lines are partly traceable. Hindwing white, brown at the costal margin with the beginnings of white transverse lines, inner margin and distal margin narrowly brown. Brazil (Castro, Parana).

arpi. **D. arpi** *Dogn.* (150 i) is similar, larger, the whole basal third beautifully bluish-green, distally bordered by the median line, which is only visible in the lower half, and traversed by the strongly dentate black anterior transverse line; the double dentate postmedian and subterminal lines are more distinct than in *paranensis*. The white hindwing shows pink hair at the inner margin and is strewn with greyish-brown at the distal margin. Expanse of wings: 42 mm. Brazil (Novo Friburgo).

gravis. **D. gravis** *Schs.* Forewing moss-green in the basal half, strewn with blackish as far as the reddish-brown base of the inner margin and below the cell, bordered by the dark antemedian line which forms 3 distal arches and is followed by 2 fine black median lines divergent at the costal margin; the cell-end is reddish-brown, below it a dark brown shadowy stripe bordered with green above and below extends to the anal angle; the apical third of the costal margin is violettish-white, strewn with green, the distal margin below it lilac brown with black veins. Hindwing whitish, brown at the costal margin, separated from the grey apex by 2 short dark lines, inner margin and distal margin shaded with brown. Expanse of wings: 30 mm. French Guiana.

epona. **D. epona** *Schs.* Forewing greyish-green with a large grey area from the centre of the costal margin to the apex near to the brownish-green undulate submarginal line; anterior transverse lines indistinct, the posterior one dark grey, dentate, the ends of the veins brownish. Hindwing light grey with a short brown subapical line. Expanse of wings: 37 mm. Peru.

peralta. **D. peralta** *Schz.* is dull blackish-brown on the forewing with a green basal transverse line and green spots at the costal margin before and in the middle; an oblique dark shadow extends from the cell-end to the anal angle; the postmedian area behind and below the cell is lighter, the distal half of the inner margin all white, two small white spots parted by green are above it; distal margin darkened blackish, with a whitish-grey marginal line; the light brown fringe speckled darker. Hindwing dark brown with traces of a lighter postmedian line. Expanse of wings: 33 mm. Costa Rica.

atilis. **D. atilis** *Schs.* Forewing dull green mixed with brown, with a fine brownish-black inner margin, greyish-black behind the cell from the lower median nervule to the costal margin, with brownish-black veins and internerval streaks; an oval area of green strewn behind the lower cell-end with a white stripe along the upper median nervule; median line black, bordered with green inwards, cross-vein black in a reddish-yellow strigiform spot; postmedian transverse line only double white at the costal margin, darker brown postmedian and subterminal shadows; distal margin shaded with green before the fine black marginal line, brownish behind it with a darker marginal line. Hindwing blackish-brown with a feeble lighter postmedian line. Expanse of wings: 44 mm. Costa Rica.

marusa. **D. marusa** *Schs.* Head and thorax reddish-yellow mixed with brown, abdomen brownish-grey, the two last segments whitish. Forewing brown, costal base and centre of inner margin more reddish-yellow, the centre of the costal margin greenish-yellow with 3 dark lines; the very fine dark median line is double, vertical; a white crescent parted by red-brown is at the cross-vein, inwardly bordered by a narrow dark shadow which extends above vein 2 to the margin; postmedian line red-brown, distally bordered with white, an area strewn with greenish and yellowish-white is behind it between 3 and the costal margin as far as the apex; subterminal line likewise red-brown, distally bordered with white, a broad blackish-brown shadow behind it, the anal area light yellowish-green; a whitish postmedian area between 1 and 2. Hindwing dark brownish-grey. Expanse of wings: 41 mm. Guatemala.

D. mystica Schs. has grey forewings strewn with brown, basal area green with an oblique white sub-basal line, lilac brown in the cell with a reddish-yellow spot at the end, enclosing the red-brown discal streak, a blackish oblique shadow below it extends to the anal angle; green dusting behind the cell obliquely towards the costal margin; the black transverse lines are finely dentate, the posterior one partly double, red-brown spots are before the brown subterminal shadow, a dark oblique subapical shadow behind it. Hindwing brownish-grey, fringe light, dotted black. Expanse of wings: 39 mm. Costa Rica. *mystica*.

D. perplexa Schs. (150 k). Forewing deep red-brown with a violet tint, green at the base, inner margin, distal half of the costal margin and subterminal area excepting two grey stripes between the lower radial and median nervules, with black dentate transverse lines, the posterior one treble, the anterior one double; a black transverse streak at the cell-end. Hindwing white, veins and margins brownish, with a black marginal line. The larger ♀ is lighter, the green more extensive, 3 black spots each before the margin above the anal angle and subapically. Hindwing quite brownish-grey with lighter fringe. Mexico to Costa Rica. *perplexa*.

D. druona Schs. Forewing light yellowish olive, cell and basal area strewn with black, with a blackish shadow from the lower cell-end to the margin between 3 and 1; a blackish-brown streak at the cross-vein; transverse lines undulate-dentate, black and white vein-dots behind them; a faded brown subterminal shadow is widened between 4 and 6. Hindwing brown, olive green at the costal margin with the beginnings of dark lines. Expanse of wings: 37 mm. French Guiana. *druona*.

D. carantis Schs. Forewing dull green at the costal margin, purple brown below it with a light brown patch from the cell-end to the apex; antemedian line black with 2 white dots at the inner margin; a green streak bordered with white at the cross-vein; postmedian line black with white vein-dots, indistinct, the veins behind it strewn black and white; small blackish-brown subterminal spots, a green interrupted marginal line behind them. Hindwing blackish-brown with a feeble lighter straight postmedian line, dusted with green at the costal margin, with the beginnings of dark lines. Expanse of wings: 36 mm. Guatemala. *carantis*.

D. sylla Drc. (= novella Schs.) (150 k) has brown forewings, green at the margins excepting the apex, the dark transverse lines indistinct, shadow-like, the antemedian line double at the costal margin; blackish shading before and below the light brown cross-vein, a small white spot behind the centre of the costal margin; a light brown shadowy stripe before the dark subterminal shadow which terminates above the anal angle; fringe pinkish-brown, speckled darker. Hindwing brownish, scantily scaled, darker at the inner and distal margins, with a dark, distally lighter postmedian line. Mexico to Costa Rica. *sylla*.

D. nystalina Fldr. Forewing greenish olive, mixed with brownish, with double dentate transverse lines, the distal half of the median area broadly darkened at the costal margin, narrowly at the inner margin, enclosing the double dark cross-vein streak in a small light spot; black subterminal wedges. Hindwing brownish pink, with a broad blackish-brown marginal band and a small yellowish anal spot. Expanse of wings: 36 mm. Amazons. *nystalina*.

D. livida Schs. (150 k) is a beautiful species, sexually very dimorphous. ♂ with green forewings with steel-blue spots at the bases of the costal and inner margins, with fine double transverse lines and a small brown cell-end spot surrounded by light green; a dark green oblique shadow from the cell to the centre of the inner margin, bluish-grey shading behind it also in the cell; a dark green postmedian band as far as the broad steel-blue subterminal line, shaded with blackish-brown, a light green spot at the apex. Hindwing brownish-grey, whitish basally, the black postmedian line shaded with light outside. The ♀ has light steel-blue forewings with double notched black transverse lines, the anterior lines shaded with green, the posterior lines with brown, with a brown area behind and below the cell; the thick black subterminal line is bordered with white and brown distally. Costa Rica. *livida*.

D. cariba Schs. Forewing brown with a green basal band traversed by two black lines, the green undulate median band bordered with brown and parted by a brown line, the area behind it light brown and dusted with lilac, grey before the cross-vein and between the median nervules; the treble postmedian line is interrupted by green above the median nervules. Costa and distal margin green, the latter bordered inside by the whitish-green undulate line. Hindwing lilac brown, distal margin broadly purple brown, traversed by a darker band. Expanse of wings: 42 mm. Guatemala. *cariba*.

D. delecta Schs. has olive green forewings dusted with white in the distal half at the costal margin and behind the cell, with double blackish-brown transverse lines, the posterior one spotted white, the median line bordered with white outside at the costal margin; the feeble brownish subterminal shadow is dentate. Hindwing brownish-grey, with a double postmedian line at the costal margin, followed by a small white apical spot. Expanse of wings: ♂ 35, ♀ 45 mm. Costa Rica. *delecta*.

D. apparata Schs. Forewing apple-green with a black basal ray, double black dentate transverse lines, brown spots before the anterior line at the costal margin and below the cell as far as the inner margin, the centre of the costal margin and an oblique blotch between the median nervules are dusted with bluish-white; the light brown cross-vein is surrounded with deep blackish-brown, darker green dusting before it; undulate-linear shadow black. Hindwing brownish lilac, fringe green, the short postmedian line at the costal margin is bordered with white outside. Expanse of wings: 39 mm. Costa Rica. *apparata*.

- remuria*. **D. remuria** Drc. (150 k) has green forewings with fine deeply dentate black double transverse lines and a double row of dots behind the distal line, and fine black veins in the marginal area. Hindwing brownish-white with a broad green costal margin and a double postmedian line in it. Mexico to Brazil, a common species.
- viror*. **D. viror** Dogn. (151 a) is similar to *remuria*, smaller, the lunar arches of the transverse lines filled with violettish-brown like the cell-end spot which is followed by a strongly angled median line, white vein-dots behind the postmedian line, a subterminal row of violettish-brown spots behind them. Hindwing whiter than in *remuria*, tinged with green also at the margin. Bolivia, Colombia.
- jamaicensis*. **D. jamaicensis** Schs. Forewing light green, the ends of the veins fine black, with fine reddish-brown double dentate transverse lines and a large reddish-yellow discal spot, 2 short double transverse lines above it at the costal margin; the postmedian line is finely shaded dark outside, the subterminal shadow reddish-brown. Hindwing light reddish-brown, broadly brown at the distal margin, green at the costal margin, with short darker double lines and a black marginal line. Expanse of wings: 50 mm. Jamaica.
- caluna*. **D. caluna** Schs. is allied to *herbida*. Forewing yellowish-green, with a black basal ray and indistinct darker antemedian and median oblique lines; a dark grey spot behind the dark cell-end streak, a similar one between the median nervules; the undulate line is marked by several small black spots, followed by an undulate light line. Hindwing whitish-grey, yellowish at the inner margin. Expanse of wings: 30 mm. Brazil (Castro, Parana).
- herbida*. **D. herbida** Wkr. Forewing moss-green, strewn with blackish, the most intensely in the postmedian area, with a blackish feeble basal ray and darker green dentate antemedian and postmedian transverse lines and a dark cell-end streak; a spot of dark grey dusting is between the base of the two median nervules; somewhat darker shading is before the lighter green undulate line; fringe speckled green and blackish. Hindwing brownish-grey, yellowish towards the base. Expanse of wings: 40 mm. Described from Brazil.
- lucoides*. **D. lucoides** Schs. is very similar to *herbida*; forewing yellowish-green, strewn with olive green, forming a large spot around the cell-end; the double dark deeply dentate transverse lines are shaded dark green below the cell, the light cell-end streak is shaded dark outside; dark green subterminal lunular shadows, those in the middle being thickest, an olive green shadow behind them; fringe speckled dark, dark internodal dots before it. Hindwing brownish pink with a lighter postmedian shadow. Expanse of wings: 40 mm. Costa Rica.
- barensa*. **D. barensa** Schs. is dark green at the base and inner margin, with 2 irregular black antemedian transverse lines and a whitish spot at the cell-end, the distal half grey strewn with green which forms indistinct spots subterminally and at the margin; a dentate median line and double postmedian line are traceable. Hindwing white, narrowly green at the costal margin with a small dark anal spot. Brazil (Castro).
- foliata*. **D. foliata** Schs. Forewing dull moss-green, strewn with black in the basal half of the inner margin and with single finely dentate black transverse lines, the veins behind the postmedian line are fine black; cross-vein dark brown, a grey shadowy spot below it; brown submarginal internodal spots. Hindwing brownish, moss-green at the costal margin, with 2 short black lines in it, inner margin with brown hair. Expanse of wings: 31 mm. French Guiana.
- edwardsi*. **D. edwardsi** Drc. (= *museosa* Edw., *masta* Schs.) (151 a). Forewing brownish, finely strewn with black and mixed with green, most intensely so in a broad oblique band from the costal margin antemedianly to the inner margin as far as the anal angle, in a small apical spot and before the margin; fine black double transverse lines and a black cell-end streak surrounded by red-brown, a whitish costal-marginal spot above it; small blackish subterminal spots are surrounded by red-brown. Hindwing brownish-grey. The larger ♀ is distinguished by a large white postcellular spot finely strewn with greyish-black, extending from the costal margin to the apex and below as far as the lower median nervule; a grey spot below the cell in the bifurcation of the median nervules. The ♀ is much more common than the apparently very rare ♂ of which I have seen only a single specimen. Mexico, Guatemala, doubtfully from S. W. Arizona.
- baracoana*. **D. baracoana** Schs. (= *habilis* Schs.) (151 a) is similar to *edwardsi*, the ♂ lighter and much less distinctly marked, the grey spot below the lower cell-angle being the most distinct; white vein-dots between black ones are behind the postmedian line. Hindwing more whitish, brownish at the costal and inner margins, a short dentate white postmedian line at the costal margin. The ♀ is easily distinguishable by a large purely white postmedian spot, the subapical spot on the hindwing being much larger, too. Antennae strongly pectinated also in the ♀, plain in *edwardsi*, tegulae white. Mexico to Brazil.
- discata*. **D. discata** Schs. Forewing moss-green with single grey transverse lines, the interior one whitish at the inner margin, the posterior one dotted white on the veins; a white large spot at the cell-end, a smaller one above it at the costal margin; instead of the undulate line there is a blackish indistinct shadow. Hindwing white, with yellow hair at the inner margin, moss-green at the costal margin. Expanse of wings: 37 mm. Brazil (Castro, Parana).

D. albidiscata Schs. has white forewings strewn with brown except a quadrangular purely white *albidiscata*. discal spot and a broad subterminal shadow which is the most distinct at the costal margin; a narrow brown band at the margin is traversed by white veins. Hindwing light brown, scantily scaled, darker at the distal margin. Cuba (Tanamo).

D. splendens Drc. (151 a) is scarcely mistakable for any other species owing to its white forewings *splendens*. with the large green costal-marginal spot of the same oblong shape as in the genus *Rhoda*, as which *splendens* was also described. Panama, Costa Rica to Colombia and Bolivia.

D. lloreda Dogn. (= *amata* Drc.) (151 a). Forewing green, with large brown spots at the inner margin; *lloreda*. the fine brown transverse lines are most distinct at the costal margin, only the postmedian line is better visible. Hindwing whitish-grey, broadly greenish at the costal margin. Colombia.

D. lama Schs. Forewing violettish-brown, costal margin, apex and the space between the veins *lama*. 3 and 4 moss-green with black transverse lines, the anterior one single, the posterior one treble, submedianly connected with a distinct undulate median line by a streak; the postmedian line exhibits a white crescentiform streak at the inner margin, a yellow spot is in the cell-end; small faint brown marginal spots between the ends of the veins; hindwing whitish, brown at the inner and costal margins, the latter with the beginnings of three darker lines. Expanse of wings: 36 mm. French Guiana.

D. poulsoni Schs. (151 b). Forewing green, strewn with blackish, with a broad light reddish-yellow *poulsoni*. inner-marginal stripe as far as the postmedian line, reddish-brown behind it, the space between the median nervules and also the cell-end shaded with brown, vein 3 striped yellowish-white outside, small white vein-dots behind the indistinct double postmedian line. Hindwing whitish, inner and costal margins brown, the costal margin strewn with green. Guiana, Brazil.

78. Genus: **Seirotonta** Grt. & Rob.

The only distinctive mark of the species, the distally concave cross-vein, is too insignificant to found a special genus on it. We separate it nevertheless from the preceding genus, because *bilineata* might be looked for under *Seirotonta*.

Type of genus: *S. bilineata* Pack.

S. bilineata Pack. (= *turbida* Wkr., *associata* Wkr., *ulmi* Harr.) (151 b) is mouse-coloured on the *bilineata*. forewing, generally somewhat darkened between the two fine dark brown dentate and somewhat lighter-edged transverse lines; the cell-end is marked by a black, insignificant streak; submarginal line very feeble. Hindwing lighter grey with a small dark anal spot. — Larva green with white dorsal and subdorsal lines, the latter broader and bordered with yellow and red, almost contiguous with the dorsal line on the first segments and bordered with deep red inside. It lives on elm trees and more rarely on beeches. Atlantic States. — f. **exsanguis** Dyar, *exsanguis*. from Texas, is a smaller and lighter form, more bluish-grey, of a more reddish flesh-colour in the median area, with a more distinct subterminal shadow.

79. Genus: **Dunama** Schs.

Very closely allied to *Disphragis*, distinguished by the somewhat more erect palpus with a longer middle joint and scales instead of hair. Neuration of forewing as in *Disphragis*; hindwing with a straight costal margin. of a broad shape, the costal vein proceeds before the centre of the cell, the nervules arising from the upper cell-angle are not stalked, those from the lower one from one and the same base. Only one small species.

Type of genus: *D. angulinea* Schs.

D. angulinea Schs. Forewing greyish-brown, near the base with a small reddish-yellow costal-marginal *angulinea*. spot; instead of the anterior transverse line there is a dark triangular costal-marginal spot and a round one below the cell; median line double only visible below the cell, the postmedian line is a brown shadow, double vein-dots parted by light behind it, whitish dusting between it and the median line below the cell; light dusting behind the brownish-grey subterminal shadow, then black marginal spots. Hindwing greyish-brown. Expanse of wings: 22 mm. Costa Rica.

80. Genus: **Malocampa** Schs.

Exactly like *Disphragis*, only separated by dense hair and scales of the somewhat concave costal margin of the hindwing in the basal part. Forewing somewhat longer and narrower on an average than in typical *Disphragis*. Many tropical species have been described.

Type of genus: *M. punctata* Cr.

M. punctata Cr. (= *bifurcata* Sepp.) (151 b) is a large well-known species apparently very variable *punctata*. according to different districts. *Ziliante* Stoll in my opinion also belongs to this species and represents a specimen

without the usual darkening at the cell-end. Forewing greyish-white, all the transverse lines broken up into double rows of thick black dots, with a more or less dense greyish-black median shadow which is usually densest at the cell-end and mostly vanishes below it, but it may also be continued to the inner margin; mostly some brownish dusting submedianly and apically. Hindwing whitish, more or less smoky, with dark brown veins and a fine marginal line, more intensely dusted brownish-grey in the ♀ which is often very large. — I cannot decide at present whether a much smaller form — f. n. *illimis* (151 b) — with purer yellowish-white forewings with very scanty dusting and much smaller black dots which are also scantier, almost absent subterminally, with yellowish-white unmarked hindwings, is a distinct species; a similar species is figured in Ann. Carnegie Mus. XV, 1923, pl. IV fig. 19, originating from Bolivia. The type in Coll. DRAUDT is from Mirador, Mexico, and was taken on March 27th 1903. It has therefore surely a wide range.

satis.

H. satis Drc. (= *punctata* Drc., *parvipuncta* Schs.) (151 c) looks like *D. manteo*, the forewings are longer, the whole surface quite uniformly strewn with dark, all the transverse lines broken up into double dots, beginning at the costal margin with oblique brownish streaks; 2 black dots above each other at the cell-end; the light undulate line is shaded somewhat darker inside. Hindwing greyish-brown with yellowish-white fringe and a whitish postmedian line ending in a larger spot at the anal angle. Mexico to Panama, here in a somewhat lighter form.

hibrida.

M. hibrida Dogn. (151 c) is exactly like *Disphragis punctata* Drc. on the forewing, whilst the hindwing is like that of *satis*. Expanse of wings: 39 mm. Colombia.

sorex.

M. sorex Schs. Forewing dark greenish-grey, strewn with brown and black with shadowy transverse lines, the anterior one from the first third of the costal margin to the centre of the inner-marginal vein where it cuts a postmedian line; 2 black dots above each other in the cell-end are in a dark short costal-marginal shadow; behind the postmedian shadow there is a double row of black dots with white ones between them, a submarginal shadow is only visible in the upper two thirds. Hindwing dark brown, with yellowish hair at the inner margin, and yellowish fringe. Expanse of wings: 37 mm. French Guiana.

omaita.

M. omaita Dogn. is somewhat similar to *sorex*; forewing light grey, strewn with red-brown, the two transverse lines not cutting each other, the anterior one double at the costal margin, with single white dots, the posterior one treble at the costal margin, then as a double row of black dots parted by white; the median shadow continued to the inner margin into denser shading, the red-brown subterminal shadow also with single white dots. Hindwing blackish with white fringe, central dot and anal spot. British Guiana.

randauta.

M. randauta Schs. is allied with *omaita* and *sorex*; head and thorax brown and white, abdomen dark brown, reddish ochreous beneath. Basal area of forewing brown and reddish yellow, bordered by a double line; antemedian area blackish-brown in the upper half, intensely strewn with white in the inner-marginal half, distally bordered by the double antemedian line filled with reddish, the rest of the wing reddish-brown with a light reddish reniform macula with 2 brown dots; the double postmedian line is dark brown with black vein-dots, veins blackish, strewn with white, a dark brown subterminal shadow. Hindwing brownish-grey. Expanse of wings: 40 mm. Bolivia.

lupana.

M. lupana Dogn. is yellowish-grey on the forewing, the anterior transverse line notched, the median and posterior ones shadowy, a black line forming three arches is on the posterior line, an irregular subterminal row of spots behind it; two deeper black lines forming semicircular arches are above these markings in the basal and distal halves of the inner margin, the distal one extending up to the cross-vein. Hindwing diaphanous grey, darker at the margin. French Guiana.

lupanoides.

M. lupanoides Dogn. Forewing more yellowish than in *lupana*, strewn with brown, with 3 brown lines at the base, the ground between them being whitish towards the inner margin; extensive brown shading in the distal half of the costal margin, traversed by the median and posterior transverse lines which disappear in the brown ground, the brown spot is distally bordered by a yellowish subapical oblique line; a yellowish undulate line is in the brown margin, black internerval dots behind it. Hindwing brown with yellowish fringe. Expanse of wings: 40 mm. Amazons.

eugenia.

M. eugenia Schs. has greenish-grey forewings with a silky gloss, the curved black basal line bordered with white outside below, the anterior and posterior transverse lines treble, the innermost of the posterior line brown, dentate, shadowy, the others fine, black; a reniform macula finely surrounded by black is at the cell-end, a white dentate line behind brown subterminal spots. Hindwing dark brown with reddish-yellow fringes. Expanse of wings: 57 mm. French Guiana.

maroniensis.

M. maroniensis Schs. (151 c). Forewing slaty grey with brown costal-marginal spots and a black cell-end spot; 2 black vein-dots before the anterior transverse line, single double dots instead of the posterior line, a brown band before them, angled at the lower cell-angle; hindwing brown, veins and margin darker, with a black anal spot parted by light. French Guiana; West Colombia.

M. mayeri Schs. (= *stricula* Dogn.) (151 c). Forewing brownish-grey, darker at the costal margin, *mayeri*. cell and distal margin, strewn with whitish at the base and inner margin, with 3 black double transverse lines; dark velvety brown subterminal spots in the upper half, black internerval spots behind them on the margin, lilac dusting before them. Hindwing lilac brown, veins and margin blackish-brown. French Guiana.

M. piratica Schs. (151 c). Forewing grey, dusted with light brown excepting the margins, the double *piratica*. transverse lines proceed from large black costal-marginal spots, the inner margin behind the anterior line is dark brown and black; a white dot at the cell-end, a brown streak above it, a dark subterminal shadow behind the cell and a small black anal spot. Hindwing blackish-brown, fringe yellowish. French Guiana.

M. bolivari Schs. (151 c) is very similar to *piratica* in the marking, but the forewing is white, mixed *bolivari*. with brown not black at the inner margin, in the ♀ as a triangular surface which is connected with the anterior brown costal-marginal spot by a fine brown line. Hindwing greyish-brown, fringe whitish. Venezuela. ♀ with pectinated antennae.

M. puella Dyar (151 c) looks exactly like *bolivari*, but the ♀ has plain antennae; forewing with a *puella*. very slight yellowish tinge excepting the margins, the ♂ strewn somewhat brownish, with a prominent white double cell-end dot in it, shadow-like traces of a double postmedian line behind it, sometimes with single black vein-dots; fringe speckled white and dark brown. Mexico to Venezuela.

M. albolineata Drc. (151 d). Forewing light greyish-brown with brown costal-marginal spots as in *albolineata*. *puella*, but without the broad triangular inner-marginal spot, only somewhat more intensely dusted with brown which extends to the anal angle; 2 purer white dentate lines and the white cell-end streak are distinctly visible. Hindwing light brown, darker towards the margin with light fringe. Mexico to Brazil, much darker in the south; Mexican specimens from Misantla, Orizaba and Jalapa are of the same silvery white colour as *puella*, only discally very slightly tinged with brownish: — f. n. **mexicana** (151 d), but those from Tabasco are *mexicana*. brownish.

M. argentata Drc. (151 d) is very similar to the white form of *albolineata*, but more silvery grey, with *argentata*. black-dotted veins, a large black spot near the anal angle. Hindwing lighter reddish-grey with a small black anal spot. Costa Rica, Panama.

M. matralis Schs. Forewing dull brown, with a reddish-yellow tinge at the inner margin, the double *matralis*. anterior transverse line only marked at the costal margin, the posterior one composed of grey vein-streaks surrounded by black double dots; 2 small black spots at the cell-end are surrounded by light brown, black internerval dots on the margin. Hindwing dark brown, fringe reddish-yellow, a dark and light anal spot. Costa Rica.

M. friburga Schs. has light brown forewings, whitish at the inner margin, strewn with blackish, and *friburga*. with single dark brown transverse lines, black double dots parted by white behind the distal line, 2 small black spots at the cell-end, a narrow dark subterminal shadow, black internerval dots behind it. Hindwing light brown, darkened at the costal margin, with a darker postmedian line and small dark spots at the inner margin and anal angle. Brazil (Novo Friburgo).

M. sida Schs. (= *sidoides* Schs., *canescens* Dogn.) (151 d) is very similar to *friburga*, smaller, much *sida*. darker brown, contrastingly white at the base of the inner margin and above the anal angle, slightly clouded grey, transverse lines more linear, not so much broken up into dots. Mexico to Brazil.

M. trepsora Dyar (151 e) has broader wings than *sida*, marked almost the same, but without any *trepsora*. white, only with slight traces above the anal angle at the distal margin and a little subcostally at the apex; the beginning of the transverse lines at the costal margin somewhat widened and darkened. Hindwing dark brown, the light fringe speckled dark. Mexico (Zacualpan).

M. lunula Dogn. (151 e). Forewing greyish-white, strewn with brown, with a large brownish-black *lunula*. spot at the submedian base as far as behind the centre of the cell, and a triangular spot, the apex of which is at the cell, the two sides ending at the costal and inner margins shortly before the apex resp. the anal angle, but leaving the margin itself white; double transverse lines almost only visible at the costal margin, discal dot and undulate line white, fringe white speckled with brown. Hindwing blackish, the anal spot parted by white. French Guiana.

M. mammerta Schs. (151 g) is somewhat similar to *lunula*, smaller, of a purer greyish-white on the *mammerta*. body and the basal half of the costal margin of the forewing, not strewn with brown, with a less contrasting white marginal part; transverse lines more distinctly double, the reniform macula larger, roundish, contred dark brown. Hindwing white, feebly dusted with brownish-grey, and with darker veins. Brazil (Rio Purns).

M. obliquata Schs. is a small species with grey forewings, the basal half light brown, white above *obliquata*. the anal angle, with traces of an anterior transverse line, and a row of dots in the centre of the cell; the curved brown median line is bordered with black below the cell and with moss-green at the inner margin, here with a short black line before it, close behind it follow 4 black lines partly filled with brown, partly

whitish-grey; a white streak at the cell-end, a black dot outside above it, then follows a dentate black postmedian line with vein-streaks and small brown spots behind them; the black undulate line is situated towards the costal margin in a brown oblique shadow. Hindwing greyish-brown, whitish basally. British Guiana.

broma. **M. broma** Schs. (= *dentifera* Dogn.). The forewing of this small species is greyish-brown at the base and costal margin, whitish in the median area, strewn with brown in the cell, grey and lilac at the inner margin, dark brown behind it in the upper half, lilac grey below it; a yellow antemedian and postmedian spot below the cell, a white streak at the cell-end; posterior transverse line double, the dentate submarginal line black, only visible in the upper half. Hindwing lilac brown, darker towards the margin. Expanse of wings: 32 mm. French Guiana.

spurea. **M. spurca** Schs. has dingy white forewings scantily strewn with brown, with a large blackish-brown triangular spot from the first third of the costal margin to the apex, extending downward almost to the centre of the inner margin; black vein-dots instead of the posterior transverse line; internerval dots before the margin alternate with black fringe-dots. Hindwing whitish, strewn with brown, with a dark, distally whitish median line. Expanse of wings: 30 mm. Dutch Guiana (Paramaribo).

paramaribena. **M. paramaribena** Schs. Forewing black in the basal half, reddish yellowish-brown behind it, with two light brownish bands in the basal part before the middle, with a large and a small black postmedian spot at the costal margin, another spot above the upper median nervule, fringe speckled black. Hindwing dingy white, light brown at the costal and inner margins. Expanse of wings: 40 mm. Dutch Guiana (Paramaribo).

ecpantherioides. **M. ecpantherioides** Schs. (= *splendens* Drc. 1911 nec 1887, *muscipilosa* Dogn.) (151 e) and the following species are distinguished by yellow hindwings bordered with blackish-brown; forewing brownish-grey suffused with pink, darkened in the basal third, with 4 strong black transverse lines, an irregular dentate double postmedian line and a series of irregular blackish-brown subterminal spots. Hindwing reddish ochre in the basal part and at the inner margin. Brazil.

amanthis. **M. amanthis** Schs. is allied to *ecpantherioides*; forewing grey in the basal half with 3 double transverse lines, yellowish in the distal half, grey only at the distal margin, a black streak at the cell-end and 4 fine black postmedian transverse lines, with oblique internerval streaks at the margin, double fringe-dots at the ends of the veins. Hindwing yellow with a greyish-brown distal margin. Expanse of wings: ♂ 50, ♀ 63 mm. French Guiana.

querula. **M. querula** Dogn. (151 e). Forewing grey, strewn darker and mixed with yellowish basally, in the centre and subterminally, with numerous parallel transverse lines hardly contrasting with the ground-colour, 5 of them in the first quarter of the costal margin more distinctly marked, 3 behind the middle, the innermost more dentate, the second most distinct, and 2 subterminal ones. Hindwing blackish with lighter fringe. Expanse of wings: 47 mm. French Guiana.

queruloides. **M. queruloides** Dogn. (151 f). Forewing grey with a brownish tint and fine black lines: an oblique subbasal one, one before and behind the middle, as well as a subterminal one, with a row of blackish internerval spots before them, two of which below and above the radial branches are removed more towards the margin. a reniform macula at the cell-end is finely surrounded by black. Hindwing greyish-brown. Expanse of wings: 46 mm. Brazil.

medommoca. **M. medommoca** Schs. (151 f). Head white, collar reddish ochre, thorax blackish-brown with white tegulae. Forewing olive grey with a fine black line from the base of the costal margin to the inner margin at the anterior transverse line which is fine black like the undulate-dentate posterior line; a reniform macula at the cell-end is finely surrounded by black, with a black spot below; subterminal black spots. Hindwing dark brown with white fringe. French Guiana.

danala. **M. danala** Drc. (151 e). Forewing dark brown with fine undulate black transverse lines and a reddish-brown spot at the cell-end; a light brown undulate submarginal line, a series of small black spots behind it, the anal ones of which are much larger. Hindwing blackish-brown, yellowish at the base, inner margin and fringe. A large species from Costa Rica and Panama.

obscura. **M. obscura** Schs. (151 f) has violettish-brown forewings with a reddish-brown basal area and an olive oblique shadow from the first basal third to the centre of the inner margin, traversed by an interrupted black line; a large round olive spot at the cell-end, the dentate black postmedian line is double, its distal half in the lighter brown marginal area which is shaded with olive before the apex and anal angle. Hindwing brown with a light anal spot bordered with black above and below. Expanse of wings: 49 mm. Colombia.

bronacha. **M. bronacha** Schs. is allied to *obscura*. Head and thorax blackish-brown, abdomen lighter and more reddish. Forewing blackish-brown, dusted lighter brown, with a reddish ochreous basal area; the fine black transverse lines are bordered with a lighter olive brown; a round reddish olive spot at the cell-end with a small dark centre; white and black vein-dots behind the postmedian line; the brownish olive marginal area has black veins and exhibits a dark subterminal shadow between the apex and vein 4. Hindwing blackish-

brown, lighter basally, with a fine dark median line edged with light, and a black and white anal spot. Expanse of wings: 45 mm. Costa Rica.

M. amphissa Drc. (151 f) is a very large species with broad wings, hardly mistakable for any other *amphissa*, because of the whitish-grey forewing being provided with black veins and two sharply notched transverse lines, and the yellow, black-ringed abdomen. Colombia, Bolivia.

M. boettgeri Drc. (151 f). Forewing blackish-brown, traversed by two undulate black transverse lines, *boettgeri*, behind the cell; a green spot at the cell-end, distal margin and inner margin densely strewn with green scales, marginal line black. Hindwing dark brown with light fringe. Eastern Peru.

M. nigriviridis Dogn. (151 f) has blackish-brown forewings strewn with dark green along the inner *nigriviridis*, margin, also at the costal and distal margins between the veins which are strewn black and white; a small green spot at the cell-end; the black transverse lines are dentate, the anterior one single, the posterior one double, the ground behind it lighter. Hindwing blackish, lighter at the base and fringe. Expanse of wings: 38 mm. Argentina.

M. taetrica Schs. is somewhat similar to the green species of *Disphragis*, the moss-green forewing *taetrica*, with a produced anal angle, light violettish-brown at the base of the inner margin and a similar shadow behind the cell; the fine black transverse lines are double, the posterior line broken up into double rows of dots, a dentate brownish shadow before it around the cell-end to the centre of the inner margin. Hindwing dark brown, lighter towards the base and at the inner margin, with a black and white anal spot. Expanse of wings: 36 mm. French Guiana.

81. Genus: **Magava** Wkr.

♂ antennae serrate, with ciliary tufts, which are long in the basal halves; palpi rising, with a hairy middle joint and very short terminal joint. Forewing exactly like that of *Malocampa*, hindwing broader with a long-haired inner margin, neuration as in *Disphragis*, the costal branch proceeds a little behind the centre of the cell. Three tropical American species.

Type of genus: *M. multilinea* Wkr.

M. multilinea Wkr. (151 g) is unmistakable for its yellowish-white forewing being alternately trans- *multilinea*, versed by numerous orange and violet transverse lines. Costa Rica to Colombia and Bolivia.

M. marginata Schs. (= *incurvata* Jones). Forewing white, scantily strewn with reddish, more densely *marginata*, at the distal margin, strewn with black at the inner margin, with double bluish-black transverse lines, an oblique basal one, a median one which is only double at the costal and inner margins, and a distal one arising near the margin before the apex and extending in an inward curve to the inner angle. Hindwing white, finely strewn with red-brown, with a long hair-pencil at the inner margin. Expanse of wings: 46 mm. Brazil.

M. forensis Schs. is very much like *marginata*, but the hindwing is dark brown with white ends of the *forensis*, fringe; forewing white, strewn with light brown, dark greyish ochre at the base, bordered by the oblique double antemedian line; a white streak with a brown dot at the cell-end, from where a feeble brown line extends to the inner margin; described from Guatemala.

82. Genus: **Thyana** Dogn.

Very similar to *Magava*, separated by a raised hair-tuft on the first abdominal segment, long hair of the cell on the forewing beneath, and with 3 rows of hair on the subcostal vein, cellular fold and median vein of the hindwing beneath; vein 7 of forewing arises from the lower distal angle of the areole, the two next veins stalked from the upper angle; the two pairs of veins arising from the cell-angles on the hindwing are stalked, the costal vein arises from the distal third of the cell. Only 1 species:

Th. sumptuosa Dogn. (151 g) resembles a *Thyatira* in the colour and marking, the brown forewing *sumptuosa*, exhibiting oval white spots, the longest spot extending from the base of the inner margin almost to the fourth fifth and being traversed by 4 transverse lines. Hindwing blackish brown with a white anal spot parted by black. Bolivia, Amazons.

83. Genus: **Rhuda** Wkr.

The ♂ antennae are shorter ciliated than in *Thyana*; the distal margin of the long narrow forewing is not entire, but feebly dentate, neuration as in *Disphragis* excepting the costal vein of the hindwing arising only shortly before the cell-end. Numerous species partly very difficult to separate have been described.

Type of genus: *R. foveola* Cr.

- focula*. **Rh. focula** Cr. (= *basifera* Wkr.) (151 g). This and the following 10 species all exhibit the same character of marking and colouring: the white forewing partly tinged with pink, with a large trapezoid deep olive brown costal-marginal spot, 3 or 4 dentate black transverse lines above the anal angle and a brown darkening from the base of the costal margin obliquely to the anal angle, enclosing a more or less silvery white streak at the base of the inner margin; hindwing coloured yellow of variable extent. *focula* is the oldest species known, large, without bluish-grey dusting at the base of the inner margin, hindwing of ♂ yellowish with narrow brown faded margin, hindwing of ♀ much more darkened. Guiana.
- geometrica*. **Rh. geometrica** Schs. differs from *focula* in the pure white area without the intense strewing and linear marking; hindwing yellow with a broad black distal margin and distal costal half, fringe yellow. Expanse of wings: 62 mm. Brazil (Rio de Janeiro).
- decepta*. **Rh. decepta** Schs. (151 g) is exactly like *focula* on the forewing, while the hindwing is more like that of *tuisa* which, however, is smaller. The under surface is very different and of a complicated colouring. Forewing here dark purple grey, the inner margin as far as the anal angle and a broad stripe below the cell and vein 4 yellow; distal half of costal margin white, with black spots and stripes, subterminally below it a notched whitish undulate line with black wedges before it between 6 and the costal margin, and a black sagittate streak behind it above vein 7; triangular yellowish marginal spots between 5 and 8. Colombia.
- tuisa*. **Rh. tuisa** Schs. neither shows a bluish tint in the basal inner-marginal irroration; the distal border of the costal spot extends from vein 4, at a distance of 4 mm from the margin, obliquely to the costa, and is not rectilinear, but finely dentate; the margin behind the undulate brown marginal line is densely strewn with brown. Hindwing yellow, distal margin and border broadly black. Costa Rica.
- difficilis*. **Rh. difficilis** Schs. (151 g) is larger than the preceding species and differs in the different course of the distal border of the costal spot which extends slightly incurved to the apex, not dentate; the distal margin is brown below vein 5, shaded with yellow above it. Hindwing of the ♀ which is only known hitherto brownish-black with yellow inner margin and fringe, and a yellow postmedian spot between the veins 2 and 5. Costa Rica.
- lorella*. **Rh. lorella** Dyar (151 h). This and the two next species exhibit the basal inner margin below the silvery white longitudinal stripe dusted with bluish, the brown costal spot is long, slightly incurved distally as in *difficilis*, hindwing blackish-brown, the inner margin and a small spot above vein 2 of the hindwing yellowish ochre. Forewing broader and more quadrangular than in the other species. Brazil.
- labella*. **Rh. labella** Dyar (151 h) is a large species with long pointed forewings, marked almost exactly like the following much smaller species, but with entirely ochreous hindwing with a narrow brownish-black distal margin and yellow fringe. Brazil, Novo Friburgo.
- minor*. **Rh. minor** Schs. (= *opalistriga* Rothsch.) (151 h) resembles *labella* in the markings of the forewing, which differ from those of *labella* in their being spotted and interrupted above the anal angle, while in *labella* they are proximally accompanied by a distinct fine black line, distally by an angular white line. *minor* is much smaller, the brown tinge of the costal and inner margins distinctly olive green, the hindwing very broad dark brown at the costal and distal margins, only the disc and inner margin yellow, mixed with brown. Expanse of wings: 43 mm. French Guiana.
- dissona*. **Rh. dissona** Schs. (= *posttriangulum* Rothsch.) (151 h) differs from the preceding species in the costal spot terminating distally rounded into the costal margin and not forming a distinct angle in the centre of the lower radial branch; the white line on the submedian vein extends almost to its centre, the brown inner-marginal ground below it is intermixed with long bluish-white hair-scales. Hindwing yellowish-white, broadly brown at the costal margin, with light brown hair at the base and inner margin, and a black spot at the somewhat extended anal angle. Expanse of wings: 57 mm. French Guiana.
- lesca*. **Rh. lesca** Dyar. The white submedian line extends to behind the centre, the space below it being white and light brown, without any grey or bluish tinge; forewing broad and quadrangular. Hindwing extensively blackish-brown, the disc above the lower median branch and the inner margin light yellowish. Brazil (Castro, Parana).
- diffusum*. **Rh. diffusum** Fldr. (151 i). The silvery white submedian line projects here very much upwards. Hindwing ochreous, broadly blackish-brown at the costal and distal margins. The purer white forewing lacks the pink tinge of the other species, the olive greenish tinge is also absent, it is more reddish brown. Brazil.
- procas*. **Rh. procas** Drc. (151 i) is easily recognizable by its entirely white hindwings exhibiting yellow hair at the inner margin and a triangular blackish-brown spot at the anal angle. The white submedian line on the forewing is continued to the anal angle.
- dimidiata*. **Rh. dimidiata** Herr.-Schäff. (= *endymion* Schs.) (151 i) differs entirely from the preceding very homogeneous forms. Forewing brown in the costal two thirds, separated by a black line, which is notched

towards the distal margin, from the whitish-grey inner-marginal part which is strewn with brown, the transverse lines are indistinct and interrupted, a somewhat lighter brown reniform macula at the cell-end. Hindwing whitish, broadly brownish at the inner margin. Brazil.

Rh. trepida *sp. n.* (151 i) is similar to *dimidiata*, but somewhat larger and much lighter and more *trepida*. unicoloured, strewn with blackish and brown on the whitish ground, without the red-brown colour of the costal-marginal part; of the black longitudinal line only two dents before the margin are present, the whole interior portion, which separates the brown and greyish-white colours in *dimidiata*, is absent here; the other marking as in the latter, the reddish-brown, light-ringed reniform macula very distinct, also a very strongly notched postmedian line. Hindwing white, veins and marginal line finely yellowish, inner margin with yellow hair, body unicoloured brownish-grey except the first yellowish cinnamon-red abdominal segment. One female from Novo Friburgo, type in the Senckenberg Museum.

84. Genus: **Gisara** Schs.

Distinguished from *Rhuda* by much longer erect palpi, the terminal joint being almost just as long as the second which is long-haired. Forewing broader than in *Rhuda*, neuration the same, the distal margin likewise dentate.

Type of genus: *G. proene* Schs.

G. procne Schs. (= *sambana* Drc.) (152 a). Forewing grey strewn with darker grey and brownish *procne*. scales, with a large white anal spot, reddish-brown and yellowish at the apex; transverse lines very indistinct, only a double black basal line is distinct with a small whitish submedian spot behind it, and a somewhat dentate red-brown submarginal line. Hindwing greyish-brown with light fringe. Guiana to Brazil.

G. meyeri Schs. (152 a) is very similar to *procne*, the wings somewhat narrower on an average. *meyeri*. Forewing much darker blackish-grey, strewn with dark red-brown only at the costal margin and in the disc, transverse lines very indistinct; the white anal spot sharply defined inside in a scalariform way. Guiana, also from Colombia (Medina) and Peru (Rio Pachitea).

G. brewsteri Schs. is exactly like *procne* on the forewings, but it has white hindwings with strewn *brewsteri*. brown veins. Expanse of wings: 57 mm. Costa Rica (San José). — **panamensis** *f. n.* (152 a) may be a form *panamen-*
sis. of it; smaller and with narrower wings than *procne*, much lighter, head, thorax and abdomen light reddish-yellow without any grey tints; forewing with the same marking as *procne*, but the hindwing is light reddish-yellow in the basal half with a broad brownish-grey marginal band. 1 ♂ from Panama (Chiriqui); type in the Coll. STAUDINGER, Berlin Museum.

G. ionia Drc. is very similar to the preceding species, forewing reddish-brown, strewn with black *ionia*. and grey at the costal and inner margins, with a double black subbasal line and a large bluish-grey spot above the anal angle, extending upwards to the centre of the distal margin; a postmedian and submarginal row of small black spots, fringe red-brown. Hindwing dark brown, with lighter reddish-yellow hair at the base. Amazons (Manaos).

G. ambigua Dyar is likewise similar, but it is without the light anal spot, marked like *procne*, but *ambigua*. with more distinct transverse lines, the anterior one notched, black, the posterior one brown, with a row of round black spots behind it. Hindwing greyish-brown. Peru.

G. albolimbata Dogn. Forewing light red-brown, strewn with black, especially at the costal margin, *albolim-*
bata. inner margin and subterminally, with a broad silvery white band at the distal margin, which is slightly darkened apically, a subterminal row of black internerval dots in it; behind 2 black cell-end dots there is a postmedian row of small black internerval spots. Hindwing blackish. Venezuela.

G. brauni Schs. (152 a) is much more chestnut-brown, strewn with silvery white and light grey only *brauni*. in the innermarginal area, the rest of the marking exactly the same as in the preceding species, the white anal spot dusted somewhat olive towards the margin, the upper half of the subterminal area intensely strewn with blackish-grey. Hindwing lighter and more brownish than in *procne*, basally still lighter. Colombia (San Antonio).

G. metcalfi Schs. (152 a) is one of the largest species, similar to the following *subrutila*. Wings of an *metcalfi*. oblong shape, the margin more oblique and more dentate than in the others. Head and palpi very light reddish-yellow. Forewing light brown of various tinges, strewn darker, the double transverse lines rather indistinct, the posterior one strongly dentate, behind it another double line with black spots; the white anal area extends up to vein 6, but it gets narrower upwards owing to the dark dusting from the direction of the margin. Hindwing greyish-brown, lighter basally, with white fringe. Bolivia; Peru; Costa Rica.

G. subrutila Dogn. has rusty brown forewings strewn with black and ochre, with a black, light-edged *subrutila*. streak at the cell-end, with black, light-edged postmedian internerval dots and a red-brown zigzag line before them; a white sagittate spot above the anal angle. Hindwing blackish-brown. French Guiana.

85. Genus: **Dasippia** *gen. nov.*

Male antennae finely serrated with ciliary tufts, female antennae plain; palpi very long, the middle joint slender, with appressed scales, the very long terminal joint subuliform, straightly porrect; a short tuft on the vertex. Forewing broad with a sharp apex and a very slight concavity below it, distal margin slightly rounded. Vein 5 arises far above the centre of the cross-vein, 6 from the centre of the long and narrow areole; the 4 lower subcostal branches — the second and third lowest stalked — from the end of the areole; hindwing with the usual neuration, the costal vein branching off behind the centre of the cell. Only 1 species.

Type of genus: *D. didugana* *sp. n.*

didugana. **D. didugana** *sp. n.* (152 b). Forewing dark greyish-brown with finely black-striped veins, the distal half of the costal margin with red-brown internerval stripes bordered with light on both sides; in the lower half of the cell there is a somewhat reddish brown longitudinal stripe extending between the lower radials to the margin; anterior transverse line very indistinctly double below the cell, extending in the cell as a light oblique line far distally as far as the discal fold which is finely striped silvery white, somewhat thickened behind the cell and bordered with black below, continued almost to the margin, after having despatched a short streak downwards on the cross-vein; of the postmedian line only a few dark vein-dots interrupted by light are visible. Hindwing dark greyish-brown with light fringe. Described from a couple from Sa. Cruz (South Brazil); types in the Coll. SEITZ (Museum Senckenberg).

86. Genus: **Talmeca** *Schs.*

Male antennae pectinated almost to the tips, the second palpal joint long, the last joint short; legs long and slender, abdomen with a hair-tuft. Forewing long and narrow with the usual neuration; veins 3 and 4 arise near together from the lower cell-angle, vein 5 above the centre of the cross-vein, 6 from the centre of the areole, 7 and 8 stalked with 9 arise from the lower distal end of the areole. Hindwing: cellular nervules stalked in pairs, or also the two lower ones from the same place at the lower cell-angle; the costal vein arises shortly before the cell-end. Quite a number of species have been described, mostly of a *Nonagria*-like exterior.

Type of genus: *P. perplexa* *Schs.*

perplexa. **T. perplexa** *Schs.* Forewing light reddish-yellow dusted with violet, with a darker cellular shadow towards the margin, a dark cellular dot, black postmedian vein-dots and a row of internerval dots before them; veins of marginal area fine black with marginal dots between them. Hindwing lilac brown, whitish basally and at the inner margin, fringe white. Expanse of wings: 30 mm. Known from French Guiana and Trinidad.

remota. **T. remota** *Dogn.* looks like *perplexa*, but instead of the two postmedian rows of dots it exhibits a more median, distantly separated double row of red-brown streaks. Expanse of wings: ♂ 27, ♀ 29 mm. French Guiana.

lunulata. **T. lunulata** resembles *remota*, but instead of the double brown streaks it has a postmedian brown dentate lunular line interrupted on the veins. The species is apparently somewhat larger on an average, but according to the author himself both may be only forms of *perplexa*. Expanse of wings: ♀ 30, ♂ 35 mm. French Guiana.

dabuisa. **T. dabuisa** *Schs.* is reddish olive on the head, thorax and the last abdominal segments, the rest of the abdomen lighter and more yellowish. Forewing light yellowish-red, scantily strewn with brown, with a yellow stripe below the cell and vein 2 as far as the margin; base of cell shaded with brownish, a thick black spot at the cross-vein; a brown streak along vein 4 extends to a double row of black vein-dots; transverse lines composed of vein-dots, the anterior line double; greenish subterminal internerval shadows and a row of dots. Hindwing brownish, fringe white. Expanse of wings: 33 mm. Panama (Canal Zone).

agathosa. **T. agathosa** *Schs.* Head and thorax reddish olive, abdomen brown, the two last segments yellowish, ventrum white. Forewing light reddish ochre, inner margin suffused with olive, a similarly coloured stripe extends above the median vein and vein 4 to the margin; transverse lines reddish-brown, the anterior one double, the posterior one also double, followed by a double row of black vein-dots with white between them; discal spot yellowish; marginal area narrowly white with reddish olive internerval shadows before it. Hindwing dark brownish with white fringe. Expanse of wings: 33 mm. Brazil, Rio Purus.

dubiosa. **T. dubiosa** *Dogn.* is a larger species, the white forewing strewn with pink, more brownish in the inner-marginal half, with a brown longitudinal band through the cell as far as the margin, brownish veins and a double subterminal row of dots; a brown streak at the cell-end and a double row of dots below the cell as far as the inner margin, thick black internerval dots on the margin. Hindwing brownish, fringe speckled. Expanse of wings: 40 mm. Amazons (São Paulo de Olivença).

T. offa Schs. (152 b) is somewhat like *dubiosa*, but without the pink tinge, strewn with brownish *offa*. excepting a white longitudinal blotch below the brown longitudinal stripe, the rows of dots are altogether absent, hindwing white, the veins strewn with brown towards the margin. Expanse of wings: 33 mm. Bolivia.

T. biplaga Schs. is a very small species with lilac-brown forewings and 2 large black spots, one *biplaga*. below the distal half of the cell, the other one submarginally between the lower radial branches; traces of fine double transverse lines, and 3 black internerval longitudinal streaks before the margin, black dots before the fringe between the veins. Hindwing dingy white with a greyish-brown distal margin and white fringe. Expanse of wings: 28 mm. French Guiana.

T. suffusa Dogn. Forewing yellowish ochreous dusted with lilac, with a fine black antemedian line *suffusa*. and a black cellular dot; a blackish oblique submedian shadow as far as the lower cell-angle and a very broad marginal shadow are connected by a rusty brown longitudinal shadow between the median vein and the inner margin; a postmedian double row of black vein-dots, black internerval dots on the margin. Hindwing yellowish-white, veins and margin brownish. Expanse of wings: 26—32 mm. French Guiana.

T. invisa Schs. resembles *suffusa*, forewing lilac brown, strewn darker, with an oblique shadow behind *invisa*. the cell-end to the centre of the inner margin; double antemedian and postmedian rows of black dots, and one dot in the cell; veins of marginal area strewn with black with dots between them on the margin. Hindwing whitish with a greyish-brown margin. Expanse of wings: 27 mm. Known from Dutch Guiana.

T. curtoides Dogn. (152 b) is one of the smallest species, forewing white with a reddish flesh-coloured *curtoides*. tinge, dusted with yellowish-green at the costal and inner margins, below the median vein and in the cell-end, with a black cell-end streak surrounded with white, a postmedian black and green dentate line, 3 black, white-strewn streaks behind it below the apex; undulate line yellowish-green, dentate, black internerval dots surrounded by white are on the margin. Hindwing yellowish-white, blackish in the marginal half dusted with pink. French Guiana.

T. scirpea Schs. has white forewings with a light moss-green longitudinal shadow through the cell *scirpea*. to the distal margin, the inner margin and a short subapical streak are also green; black and green dentate antemedian and postmedian lines, the posterior line double and with a double row of dots behind it. Hindwing light lilac brown. Expanse of wings: 25 mm. French Guiana.

T. pulchra Schs. (152 b). The costal margin, a stripe above the median vein and the inner margin *pulchra*. of the forewing are brownish lilac, the cell-end and a stripe below the cell to the distal margin moss-green; vein 4 dark violet; the other veins violet strewn with white, partly bordered with lilac; dark oblique streaks at the costal margin, 2 before the middle, and 3 behind it, a white spot between the two last ones; a black dot on the cross-vein, the end of the median vein is striped white; a postmedian double row of black vein-dots, green internerval streaks before the margin and black marginal dots. Hindwing blackish-brown, fringe yellowish. Expanse of wings: 30 mm. Bolivia.

T. gnoma Schs. is similar to *pulchra*; forewing lilac grey, strewn darker with a green stripe in the *gnoma*. lower half of the cell and widened behind it to the margin, a stripe below the median vein and the anal half are also green; double black and brown antemedian and postmedian transverse lines interrupted on the veins, black and white vein-dots behind them. Hindwing brownish-grey with white fringe. Costa Rica.

T. consociata Schs. Forewing violettish-grey, the apical third of the costal margin, a stripe below *consociata*. the median vein and the lower median nervure, a spot at the cell-end and the inner margin light green, a violet streak surrounded with white is at the cell-end; a postmedian double row of black dots interrupted by white; the margin is shaded with lilac brown with black internerval dots bordered with white inwards. Hindwing lilac brown, fringes white at the ends. Expanse of wings: 27 mm. French Guiana.

87. Genus: **Boriza** Schs.

Male antennae ciliated, the short porrect palpi with a tiny conical terminal joint; a small hair-tuft on the frons. Forewing relatively short and broad with the same neuration as in the preceding species. Veins 3 and 4 of hindwing arise separately, vein 6 stalked with 7, the costal vein near the cell-end. Half a dozen of tropical species are known.

Type of genus: *B. crossaea* Drc.

B. crossaea Drc. Forewing dark brown, somewhat lighter analwards with several greyish-brown *crossaea*. dentate postmedian transverse lines. Hindwing white with a large blackish-brown triangular spot at the anal angle. Mexico.

B. trajecta Dogn. (= *giacomelli* Koehler) has grey forewings with a broad black longitudinal line *trajecta*. traversing the cell and terminating on vein 5, with a postmedian double row of black vein-dots. Hindwing

of a pure white colour. The male antennae of this species are pectinated, plain at the ends. Described from Paraguay.

- tonac.* **B. tonac** Schs. (152 c). Forewing light grey with fine brown internerval longitudinal lines and a black basal and inner-marginal ray; postmedian vein-dots in a broad lighter area, a black dot in the lower cell-end also in lighter surroundings. The male shows the basal half much darker, also the apex of the wing, which contains a few thicker blackish-brown rays. The type described is a female of a rather common aberration with a blackish-brown longitudinal patch from the lower cell-end to the margin between the veins 2 and 4.
- pauperata.* — The more common form without this spot I denominate: **pauperata** f. n. (152 c). Mexico.
- fuscitincta.* **B. fuscitincta** Dogn. The yellowish-brown forewing is dusted with violet, grey in the centre of the costal margin, with a black basal ray from the base of the costal margin; both the transverse lines very feeble, dentate, blackish, in grey dusting, a yellowish spot at the cell-end; median area somewhat lighter, yellowish subterminal internerval spots, some of them with black streaks. Hindwing brownish. Expanse of wings: 49 mm. French Guiana.
- povera.* **B. povera** Schs. is very different; forewing light pinkish brown with a black basal dot and two transverse lines, the anterior one angled in the cell, the posterior one obliquely from the apex to the centre of the inner margin and touched by a dark costal-marginal shadow. Hindwing blackish. Expanse of wings: 32 mm. British Guiana.
- ignatia.* **B. ignatia** Schs. Head and thorax Isabel-coloured, abdomen with blackish bands. Forewing light reddish-yellow, slightly dusted greenish, broadly red-brown and strewn with black at the inner margin and in the postmedian area excepting the costal-marginal part, intensified in the median area above vein 1 and forming a blackish-brown longitudinal streak; transverse lines marked by black scales, the anterior one double at the costal margin, 2 rows of black scales behind the posterior line, the veins here scaled black and white; apex dusted white with a black streak between 7 and 8, shorter streaks between 5 and 7. Hindwing white, shaded with reddish-yellow at the inner margin and narrowly at the distal margin. Expanse of wings: 38 mm. Brazil (Blumenau).
- argenti-punctata.* **B. argenti-punctata** Dogn. is very different. The brownish-yellow ground of the forewing with red-brown veins and several transverse rows of silvery white internerval spots bordered with dark brown; three dark violettish-brown spots: at the base of the costal margin, the second behind it extends to the lower cell-angle and along the postmedian spots back to the costal margin, the third above the anal angle. Hindwing diaphanous white. Expanse of wings: ♂ 37, ♀ 46 mm. French Guiana.

88. Genus: **Chadisra** Wkr.

A very large genus most of the species of which had been assigned to the genus *Blera* Wkr., but which were now united with *Chadisra*; the species with a more pointed apex of the forewing had belonged to *Blera*, those with a rounded apex to *Chadisra*, no other anatomical differences having existed. The male antennae are shortly ciliated, the short hairy palpi hardly project beyond the frons; neurulation not different from that of the neighbouring genera; vein 5 of forewing arises from above the centre of the cross-vein, 6 from the centre of the areole; 3 and 4 of forewing arise together from the lower cell-angle, 6 stalked with 7 from the upper cell-angle, the costal vein proceeds near the cell-end. The species occur only in Central and South America and are often very sexually dimorphous, so that it is sometimes difficult to separate them.

Type of genus: *Ch. bipars* Wkr. from Ceylon. (Vol. X, p. 636, pl. 84 f).

- politia.* **C. politia** Cr. (= *ceruroides* Wkr., *rogenhoferi* Fldr.) (152 c) represents the typical species of the genus *Blera*. Forewing white, slightly strewn with grey with finely dentate black transverse antemedian and postmedian lines shaded with dark brown on the averted sides, the posterior line much broader; the latter proceeds near the apex and extends in a distally concave bow almost to the anal angle; 3 more or less distinct fine undulate brownish transverse lines in the median area, and a streak at the cell-end, oblique scalariform streaks between the veins before the margin. Hindwing whitish, smoky at the margin. Colombia, Guiana, Brazil. DYAR proposes to separate *ceruroides* which is said to differ in the postmedian line being more excurved above the anal angle.
- nitida.* **C. nitida** Schs. has silvery white forewings strewn with single brown scales, with small brown costal spots from which two finely dentate black transverse lines proceed, the posterior one of which forms an inward dent on vein 6 and is accompanied outside by a fine brown shadow which is double behind the cell; the marginal line is composed of lunular streaks, with black dots between them on the ends of the veins. Hindwing whitish, brownish on the veins and margin, with brown hair at the inner margin. Expanse of wings: ♂ 31, ♀ 34 mm. French Guiana.

C. serra *sp. n.* (152 c) is allied to *nitida*; forewing silvery white, scantily strewn with blackish-brown, *serra*. more densely in a triangular inner-marginal area, with 2 sharply notched black transverse lines, the anterior one proceeding from a triangular dark brown costal-marginal spot, the posterior one from a tiny spot in the centre of the costal margin, then extending almost parallel to the distal fifth, forming a sharp angle on the lowest subcostal branch, from where it runs dentated to the inner margin; it is followed by a red-brown dentate line which ends behind the cell in a large dark brown triangular costal-marginal spot containing long black wedges which project distally from the brown spot as black notches; before the postmedian line there is another indistinct reddish-brown line, a white crescent at the cell-end is composed of turned-up scales; blackish-brown arcuate streaks before the margin, small black spots behind them on the veins. Hindwing white, veins and margin narrowly brownish, inner margin with brown hair. 2 ♂♂ from Joinville (Brazil), type in the Senckenberg Museum.

C. hymen *Dyar* (152 d) has longer and narrower forewings than *serra*, of a silvery grey colour, shaded *hymen*. with brown subbasally in the costal-marginal half, also subterminally except the space between the veins 3 and 4; the black postmedian line is coherent only in the lower half, with a black longitudinal ray behind it between the median branches; a purely white crescent at the cell-end, a brown spot between the veins 4 and 5 near the margin; the marginal line is composed of black angular streaks. Hindwing whitish, brown at the distal margin with a white anal spot. British Guiana.

C. larca *Schs.* is very near to *hymen*; forewing white strewn with grey, with a large violettish-brown *larca*. spot near the base of the costal margin as far as into the cell, bordered by fine black lines, the distal one of which is dentately continued to the inner margin; the posterior transverse line is partly double, lilac brown shading behind it, interrupted below vein 4 and containing black longitudinal streaks. Undulate line purely white. Hindwing greyish-brown with white cellular and inner-marginal stripes and a broad darker margin, spotted black at the anal angle. French Guiana.

C. rubiginosa *Dogn.* is also allied to the preceding species, separated by intensely red-brown irroration *rubiginosa*. and red-brown markings, so that only the distal margin exhibits the light silvery grey ground-colour; the white spot at the cell-end is S-shaped, a white cellular dot before it. The other markings as in the preceding species, but more blurred in the brown ground. French Guiana.

C. infanta *Dyar* (152 d). Forewing silvery greyish-white, with a red-brown triangular spot subbasally *infanta*. at the costal margin, edged by black lines, a few brown costal-marginal striae behind it; of the postmedian line only two spots behind the cell are present and a larger L-shaped streak filled with brown between the median nervules; subterminal area brown only in the upper half; undulate line and discal spot white. Hindwing brownish with a white postmedian band. Peru, Bolivia.

C. velha *Schs.* is somewhat like *infanta*; forewing silvery white, scantily strewn with grey, more *velha*. densely at the inner margin, with brown costal-marginal spots, a very large one below them before the centre, all finely bordered with black, the middle spot continued to the centre of the inner margin; postmedian line double, shaded with brown at the inner margin, in the upper half outside with a purple brown band enclosing 3 black small triangular spots; marginal line similar to that in the preceding species. Hindwing white, brownish-black in the distal half of the costal margin and at the margin. Brazil, Colombia.

C. finiana *Schs.* Head and thorax white, intermixed with brown, abdomen white, the 4th and 5th *finiana*. segments brown. Forewing white, strewn with light cinnamon; a brownish-black antemedian area between the subcosta and the median vein, bordered by an irregular black line, a feeble brownish shadow in the median area, and a white lunar spot at the cross-vein; postmedian line double, the interior portion shadowy, brownish, the exterior portion a very fine black line, with a broad sand-brown shadowy spot behind it between 4 and the costal margin, bordered outside by the white dentate subterminal line; a dark hook-line between 2 and 3, and a brownish spot above the tornus; marginal area between 4 and the apex dark with black marginal lunae, white below them. Hindwing white, blackish-brown at the distal margin, with a short curved apical line. Expanse of wings: 34 mm. Colombia.

C. arecosa *Drc.* (= *cacobule* ♀ *Dyar*) (152 d). The white forewing is strewn with brown and grey, *arecosa*. with a broad brown subbasal band, dying away towards the inner margin, with small brown costal-marginal spots and a very large subapical one with a smaller one below it. Hindwing light grey with a brown margin. The ♀, described as *cacobule*, looks quite different: forewing grey, the brown subbasal band traceable, with fine black transverse lines, a yellowish-white cell-end streak and 2 dots before it, with a distinct blackish-brown undulate line ending below in 2 small spots. Panama.

C. torresi *Dogn.* (= *perilleus* *Schs.*) (152 d) is similar, forewing light brownish-grey, with a large *torresi*. brownish-black spot subbasally at the costal margin, and a black undulate line behind it; an angular dark grey line in the median area and two light patches in the cell; the irregular black postmedian line is interruptedly shaded with brown outside, the undulate line broad white with small irregular black spots before it. Hindwing white, broadly dark grey at the distal margin. Brazil, Ecuador.

- lemoulli*. **C. lemoulti** Dogn. (= *hollandi* Schs.) (152 b) is another variation of the preceding species with purely white forewings with 2 very large and 2 small blackish-brown costal-marginal spots, without any other markings except a few brown scales at the anal angle. Hindwing white. The unknown ♀ may be grey and very different. French Guiana.
- tenuis*. **C. tenuis** Schs. (= *costaricensis* Dogn.) (152 e) is a smaller not rare species, marked somewhat like *larca*: forewing dull silvery white, scantily strewn with black, with fine black median and postmedian lines, with small brownish strigiform spots at the costal margin between them; behind the postmedian line follows a series of large light brown spots distally centred with black, interrupted between the veins 3 and 4; a fine black scalariform line on the margin. Hindwing white with a narrow brownish distal margin. Widely distributed from Mexico to Brazil. The ♀ shows the whole centre of the wing and the subterminal area darkened blackish-brown with a slight pink tinge.
- modulata*. **C. modulata** Schs. (152 e) is allied to *tenuis*, forewing dark grey, whitish at the inner margin at the base and in the middle, with fine black transverse lines and a white undulate line which is straight in the upper half, then twice interrupted; the black marginal line is straight in the upper half, bordered with white inside, with brown outside, then undulate, white outside. Hindwing white, brownish at the margin, quite brown in the ♀. Costa Rica.
- luculenta*. **C. luculenta** Schs. (152 e). Forewing light brown, strewn with blackish below the basal third of the cell, with a double black antemedian transverse line filled with white; the median area behind it is broad white, traversed by dentate black lines and distally bordered by a double postmedian line which is removed far inwards on the upper median nervule, so that the median area ends very narrow at the inner margin; black subterminal wedges in the upper half and small brown spots in the lower half. Hindwing white, black at the distal margin. Costa Rica.
- peirreta*. **C. peirreta** Dogn. Forewing bluish-grey, white at the base and in the centre of the margin, with fine double transverse lines and a white cell-end streak surrounded with brown. Hindwing white with a small black anal spot. Expanse of wings: 35 mm. Trinidad.
- hibrida*. **C. hibrida** Schs. Forewing grey, with a brown tinge before the centre, the anterior double transverse line filled with lighter brown, a white streak at the cell-end and a blackish-brown shadow behind it; the posterior transverse line is velvety blackish-brown shaded with brownish behind it; the distal margin behind the white undulate line is whitish dusted with brown, most densely so in the upper half. Hindwing whitish, greyish-brown at the margin. The ♀ differs in a velvety black undulate line bordered with white outside, and darker hindwings. Costa Rica.
- multifida*. **C. multifida** Schs. Basal half of forewing dark brown enclosing a darker transverse line which is double at the costal margin; a dark brown cellular spot is bordered with reddish-yellow on both sides, the posterior transverse line is velvety black, distally shaded with brown in the upper half, bordered with white in the lower half, with a velvety black longitudinal streak behind it between the veins 4 and 6, and a dark spot below it; a dark brown submarginal shadow contains black streaks in the upper half, a white dentate line behind them. Hindwing white with brown marginal line and spots at the apex and anal angle. Expanse of wings: 30 mm. French Guiana.
- chorista*. **C. chorista** Schs. Forewing white, strewn with grey, with brown costal-marginal spots and a black straight antemedian line bordered with white on both sides, a white streak at the cross-vein; the black postmedian line is shaded with brown distally, broadest above the inner margin and here with a black longitudinal streak behind it; the whitish undulate line is broad. Hindwing whitish, brownish at the margin. Expanse of wings: 38 mm. Guatemala.
- comana*. **C. comana** Dogn. Forewing white, dusted with brown and strewn with yellow, with a darker basal band bordered with yellow, and a white cell-end dot; behind the brown postmedian line follows a broad brownish-black band, interrupted by a yellow spot between the veins 3 and 4; black, white-dusted streaks are in the brown marginal area between the yellow veins. Hindwing blackish, fringe light. Expanse of wings: 36 mm. Described from a ♀ from French Guiana.
- flavodiscalta*. **C. flavodiscalta** Dogn. (= *distinguenda* Roths.) (152 e) is easily recognizable by the broad yellow discal streak on the light yellowish-grey forewing with very sinuate chestnut-brown subterminal shading. Hindwing grey, whitish in the costal-marginal half. French Guiana.
- ocrea*. **C. ocreata** Dogn. (152 e) has brownish ochreous forewings strewn with lilac grey, with indistinctly double transverse lines and a white ring-macula and reniform macula, surrounded by lilac; the broad subterminal band is light lilac grey, bordered inside by a black line. Hindwing white with a blackish marginal band. Expanse of wings: 43 mm. Bolivia (Songo).
- collema*. **C. collema** Schs. (= *praelauta* Schs.). The basal third of the costal margin on the forewing and the cell are whitish, strewn with brown, the rest brown excepting the marginal area which is white above the upper median branch and strewn with brown, transverse lines black, the posterior

line bordered with white; a dark grey shadow in the cell-end, dusted light brown before it; black subterminal spots near the costal margin and inner margin, the latter spots smaller. Hindwing brownish, darker distally. Costa Rica.

C. lauta Schs. has light brown forewings, white at the distal margin and strewn with grey, broadest *lauta*. in the middle and above the anal angle; inner margin purely white, the veins strewn with black and white, traces of black transverse lines in the brown area; the dentate marginal line is dark grey. Hindwing white with a dark marginal shadow. Expanse of wings: 31 mm. British Guiana.

C. lautina Dogn. is very closely allied to *lauta*. Forewing grey, partly mixed with reddish-yellow, with *lautina*. black fragmentary transverse lines; a white crescent at the cell-end with a white spot before it; a black crescentiform line in the white marginal area. Hindwing dingy white with a blackish marginal band. Expanse of wings: 37 mm. French Guiana.

C. ulrica Schs. Body brownish sand-coloured, intermixed with white, with a darker collar. Forewing *ulrica*. sand-coloured, dusted with brownish-grey subcostally, with brown transverse lines, the anterior ones only visible below the cell, the posterior line dentate, forming two blackish-brown crescents above the inner margin, another fine blackish-brown line behind it, being vertical between 6 and 4, then undulated to the inner margin, a brownish-black streak behind it above 2, and smaller ones above it, followed by the faint white subterminal line. Hindwing white, costal and distal margins brown. Expanse of wings: 38 mm. Amazons.

C. ezrana Schs. is similar to *lautina*. Body brownish, intermixed with white. Forewing light reddish *ezrana*. brown, costal margin, inner margin, and marginal area strewn with white, with short black basal longitudinal streaks; transverse lines indistinct, darker, double, the anterior one filled with white; 2 small black spots at the cross-vein; the brown subterminal shadow bordered with white distally, more purely white and widened below 4; marginal area spotted white. Hindwing brownish-white with darker veins and a broad dark margin and 2 white lines above the anal angle. Expanse of wings: 41 mm. Brazil (Rio Purus).

C. celsa Schs. is near *tenuis* (152 e) and *lauta*; anterior body white mixed with brownish, abdomen *celsa*. drab, somewhat ochreous basally, white at the end. The white forewing is strewn with brownish, less so in the marginal area; the dark transverse lines are fine, the antemedian line bordered inside with a purer white, scaled black behind it on the median vein and submedian fold, a small white spot at the cross-vein; a broad brown shadowy band behind the fine postmedian line, spotted black analwards, faded brown subterminal shading. Hindwing white, narrowly brown at the margin and the ends of the veins. Expanse of wings: 36 mm. Bolivia (Rio Songo).

C. emeteria Schs. differs from the similar *extranea* (153 a) in its lighter colouring and intermixed *emeteria*. reddish-yellow markings. Thorax brownish sand-coloured, more reddish on the vertex and collar, intensely mixed with white on the tegulae, abdomen brownish above. Forewing silvery white, scantily strewn with brown sand-colour, with double blackish-brown transverse lines, the subbasal line cutting a reddish-yellow spot at the base of the inner margin, the antemedian line filled with brown downward from the cell and distally bordered with reddish-yellow, a yellow crescent at the cell-end; brown dusting at the inner margin before and behind the postmedian line; a subterminal row of black internerval streaks and spots. Hindwing white, broadly brownish at the margin. Expanse of wings: 36 mm. Brazil (Rio Purus).

C. argentata Drc. Forewing dark brown with a silvery shine, with a yellowish-brown basal line and *argentata*. cell-end spot, with fine dentate black median and postmedian transverse lines; the distal margin is broadly silvery grey with a series of black marginal streaks. Hindwing greyish brown, with yellowish hair at the inner margin. Expanse of wings: 45 mm. South-Eastern Peru.

C. fitilla Dogn. (152 f) has white forewings marked brown, with double transverse lines, the anterior *fitilla*. one interrupted in the cell, the posterior one followed by dentate-like striation enclosing black spots, a white undulate line behind it; upper half of marginal line straight, lower half undulate. Hindwing white with a black costal-marginal and distal-marginal band. The ♀ is much darker with darker hindwings. Expanse of wings: 43 mm. French Guiana.

C. paragorna Schs. (152 f) is allied with *fitilla*; body brown intermixed with white hairs. Forewing *paragorna*. brownish olive, intensely dusted with white, especially basally and at the costal margin with double blackish-brown dentate transverse lines, with a white streak behind the anterior line below vein 2, the posterior line removed inwards on 5, filled with white between 2 and the inner margin, black streaks behind it between 5 and 8, and a larger spot below vein 2; marginal area more or less white. Hindwing white, broadly smoked at the margin, darker in the ♀. Panama (Lino), Brazil (Rio Purus).

C. albolilacea Dogn. Forewing white in the basal half, distally light violet with black strewing, 4 *albolilacea*. sharply dentate fine black lines in the white part, a double line on the border of the two colours; a similar

postmedian line and a shadow in place of the undulate line; marginal line dentate. Hindwing blackish with darker veins and marginal band and white fringe. Expanse of wings: 42 mm. French Guiana.

varona. **C. varona** Schs. (= *florella* Drc.) (152 f) has white forewings strewn with olive grey, an olive brown band is somewhat narrower in the cell and edged with black lines, connected at the inner margin with the double postmedian line the distal portion of which exhibits small black vein-dots; a triangular olive grey subapical spot at the costal margin. Fringe white and speckled dark. Hindwing brownish-black with yellowish fringe. Brazil (Castro, Parana). DYAR places also *Dognina peruda* to this species, distinguished by whiter forewings and white hindwings.

batama. **C. batama** Schs. Forewing brown, whitish at the base and inner angle, with a long white subapical spot enclosing 4 small black spots at the costal margin; dark double transverse lines are rather indistinct, a dark median shadow between them with a lighter cellular spot. Hindwing yellowish-white, brownish distally. Expanse of wings: 36 mm. Brazil (Rio de Janeiro).

zabena. **C. zabena** Schs. (152 f) is somewhat similar, forewing brown dusted with violettish-grey, the lower half of the distal margin white strewn with black, and the same white long costal-marginal spot enclosing 4 small black spots and 2 dark longitudinal streaks behind it; the double transverse lines very indistinct. Hindwing dark brown, lighter basad. Mexico.

zabenilla. **C. zabenilla** Dogn. (152 f) is very similar to *zabena*, but somewhat smaller, with narrower wings, the brown colour more extensive, the white subapical spot at the costal margin much smaller and dusted with grey, the lower half of the distal margin quite brown, intermixed with very few white scales; the other markings are exactly the same. Hindwing lighter, more whitish. Guiana, Colombia.

malocampoides. **C. malocampoides** Dyar. Forewing olive green strewn with grey, with round lighter spots at the base of the inner margin, anal angle and subapically at the costal margin, the veins finely strewn with black; of the fine black dentate transverse lines only the median line is double, the distal one and interior one single, the former with black vein-dots behind it; a dark brown shadowy spot at the cell-end encloses a black dot; light small roundish spots on the margin, the fringe speckled dark. Expanse of wings: 40 mm. Peru.

cucullioides. **C. cucullioides** Schs. (= *lignosa* Dogn., *pigritia* Dogn.) (152 f). Forewing light brown, strewn darker, especially behind the middle, narrowly whitish at the margin, with fine black veins; transverse lines faded, strongly notched, a thick black dot behind the postmedian line between the median nervules. Hindwing whitish, narrowly brownish at the margin with black veins and marginal line, and an anal spot parted by light. Colombia, Brazil.

89. Genus: **Rincodes** Schs.

Separated from the following genus *Talmenia* by the serrate antennae, erect stronger palpi, and long scale-tuft on the abdomen. Neuration exactly the same as that of *Talmenia*. Only 1 species:

Type of genus: *R. minuta* Drc.

minuta. **R. minuta** Drc. may coincide with *clara* Cr. IV, t. CCCC, fig. L, nec t. CCCXI. Forewing dark brown with 2 long metallic silvery stripes, the first in the cell near the base, the second behind it almost to the margin, before which there is a series of dark brown internerval stripes. Hindwing reddish-brown with a darker margin. Expanse of wings: 40 mm. Amazons, Manaos.

90. Genus: **Talmenia** Mschlr.

♂ antennae studded with short ciliary tufts, the feeble palpi porrect, scantily haired. Forewing with an obliquely rounded distal margin; vein 5 arises from the centre of the cross-vein, 6 from the centre of the arcole, 7 and 8 stalked with 9 from the apex of the areole, vein 10 arises before its end. Costal margin of hindwing somewhat convex in the basal half, apex pointed, neuration not different from that of *Chadisra*. Only 1 species:

Type of genus: *T. arsilonchoides* Mschlr.

arsilonchoides. **T. arsilonchoides** Mschlr. has light yellowish loam-coloured forewings with finely striped brownish veins and similar internerval stripes, a faint darker longitudinal submedian patch from the base to the margin between the lower radials; 2 dark dots at the cell-end; one above the other, another dot in the centre of the cell; no transverse lines whatever, a few dark vein-dots instead of the posterior line. Hindwing whitish, feebly brownish at the margin, inner margin with brown hair. Guiana.

91. Genus: **Ophitis** Fldr.

Founded upon one species, scarcely different from *Gisara*; only separated by the somewhat shorter palpi, broader forewings with a somewhat rounder distal margin; no difference in the neurulation.

Type of genus: *O. magnaria* Fldr.

O. magnaria Fldr. (152 h) is a very large blackish-brown insect with a darkened basal part which is distally bordered by a notched line, a spot like a reniform macula at the cell-end, a notched postmedian line behind it, only visible in the discal part; subterminal area somewhat lighter, enclosing a whitish undulate line, 3 thick black spots before it in the lower half; apex parted by white. Hindwing greyish-brown with a dark marginal band. Brazil.

92. Genus: **Meragisa** Schs.

A large genus of very homogeneous insects with densely hairy body and legs, also the second joint of the palpus is densely hairy, the last joint very short, hidden in the hair. The male antennae are studded with ciliary tufts as in all the preceding genera. Forewing relatively narrow, costal margin somewhat convex at the base, distal margin broad, rounded; neurulation exactly the same as in *Chadisra*. Nearly all the species have light forewings with notched mostly double transverse lines of a characteristic course.

Type of genus: *M. valdiviesoi* Dogn.

M. valdiviesoi Dogn. (152 h). Forewing greyish-white, the fox-coloured median area bordered by double black transverse lines, the anterior line oblique to the centre of the inner margin, the posterior line arising shortly before the apex, extending to the anal angle in two flat distally concave bows; a fine black crescentiform line before the margin, the lower half of which is as usual scalariform. Hindwing yellowish with a broad brownish-grey marginal band and a median shadow before it. Ecuador.

M. boliviana Dogn. is very closely allied, the forewing somewhat more intensely strewn with black, the anterior transverse line less oblique and less dentate, the distal line less distinct and more irregular than in *valdiviesoi*, only 4 mm distant from the anterior line at the inner margin, the median area more red-brown with a violet tinge. Expanse of wings: 53 mm. Bolivia.

M. semifulva Drc. Forewing greyish-white, the transverse lines red-brown, dusted with yellow basally and in the median area, with a yellow spot at the cell-end, a submarginal row of black spots. Hindwing blackish-brown with yellow inner margin and fringe. Expanse of wings: 57 mm. Peru.

M. simeona Schs. is somewhat similar to *boliviana* by the brown-strewn median area; the same strewing is below the base of the cell; wings white, dusted with brownish cinnamon at the inner margin in the basal two thirds; the thick double anterior transverse line is chestnut-brown, finely dentate, the posterior line very indistinct and fine; a fine blackish-brown line bordered with white is at the cross-vein; small orange cinnamon spots behind the blackish-brown subterminal line, a curved black line at the margin. Hindwing brownish sand-coloured with a light reddish-yellow inner margin and white fringe. Expanse of wings: 45 mm. Monte Tolima, Colombia (Quindiu Pass).

M. siavina Schs. Forewing grey strewn with brown, the usual double transverse lines are brown, with a dark cell-end streak bordered with white. Hindwing dull blackish-brown, inner margin and fringe yellowish-white. The ♀ shows the transverse lines and the distal half of the median area filled with brown, the hindwing with brown hair at the inner margin. Expanse of wings: ♂ 55, ♀ 58 mm. Costa Rica.

M. medionigra Dogn. Forewing grey strewn with red-brown in the basal area, at the costal margin and in the marginal area, the median area is black with a still darker cell-end streak in it, bordered by double transverse lines. Hindwing blackish, yellowish at the inner margin and fringe. Expanse of wings: 47—48 mm. Colombia.

M. cloacina Dogn. (152 g) introduces a group of very similar species which are difficult to separate; forewing white strewn with grey, with double black transverse lines and a black cell-end streak. Hindwing blackish, yellowish hair at the inner margin, fringe white. Colombia, Ecuador, Peru.

M. salvina Schs. is near *pallida* and *cloacina*, but not so purely white because of the brown strewing of the white forewing; the extreme costal margin is reddish-yellow, the subbasal line yellow, scaled brown distally, both the double reddish-brown transverse lines filled with yellowish, the anterior line interrupted distally in the cell; a dark median line from the costal margin to the median vein, bordered with yellow outside at the cross-vein. Hindwing brownish sand-coloured with a reddish-yellow inner margin and white fringe. Abdomen reddish-cinnamon basally. Expanse of wings: 54 mm. Guatemala (Cayuga).

M. vistara Schs. is also similar; larger, forewing silvery white strewn with reddish-brown; the double black transverse lines are filled with reddish olive like the subbasal line which is double at the costal margin; a white spot at the cross-vein with a black and reddish-yellow line, a fine dark line above it at the costal

margin; the usual black oblique submarginal streaks with small black marginal spots behind them. Hindwing brown with a reddish-yellow inner margin, a blackish-brown postmedian line and traces of a subterminal line, fringe white. Expanse of wings: 63 mm. Colombia (Buena Vista).

darida. **M. darida** Dogn. is more strewn with brown and discernible by a different course of the subterminal double line extending quite straightly between the veins 3 and 4, while in *cloacina* it forms a more distally removed dent. Expanse of wings: 48—50 mm. Peru.

dasra. **M. dasra** Dogn. (152 g) is smaller, with fragmentary transverse lines, the subterminal line forms a straight line between the veins 2 and 4. South-Eastern Peru.

pallida. **M. pallida** Schs. (152 g) differs in its purer silvery white forewings which are sparingly strewn with black, the transverse lines only double at the margins, single in the disc. Hindwing lighter brownish-grey, still lighter at the inner margin and in faint traces of a postmedian line. Expanse of wings: 45 mm. Brazil (Castro, Parana).

politioides. **M. politioides** Schs. (= *politia* Drc. part., *proxima* Schs.) (152 g). The greyish-white ground is strewn with brown and black, the black double lines are filled with yellowish scales, the marginal line is dusted with yellow inwards, like the ends of the veins. Hindwing blackish, yellowish basally. From Mexico to Brazil.

marcata. **M. marcata** Dogn. (152 i) has purer white forewings, much more distinctly black transverse lines, small black round spots behind the distal line between the veins 2 and 3, and 5 and 6; the reniform macula is almost rectangularly bent in the middle and is composed of 2 fine black lines which are open above and below; marginal line dusted somewhat yellowish as in *politioides*. Hindwing grey. Expanse of wings: 48 mm. Colombia.

inalbata. **M. inalbata** Dogn. (152 h). Forewing silvery white with double red-brown transverse lines, the anterior one rather straight, the posterior one from near the apex to the third quarter of the inner margin, removed distally between the veins 3 and 4. Hindwing as in the preceding species. Expanse of wings: 46 mm. Peru.

albescens. **M. albescens** Schs. (152 h) has white forewings sparingly strewn with light brown, with double dentate transverse lines, the anterior one black, interrupted below the cell, the interior part of the posterior line light brown, distally removed between 3 and 4; a dark brown streak at the cell-end, a very strongly dentate marginal line on the margin. Hindwing whitish-grey, yellowish in the basal half, a median line, a broad marginal shadow and the veins are darker brownish-grey. Costa Rica to West Colombia.

innoxia. **M. innoxia** Schs. is the only *Meragisa* without the double black marginal dots on the ends of the veins and thereby invariably to be determined; forewing olive greenish-grey, the dark double transverse lines similar as in all the others, filled with whitish, with another double almost straight basal and subbasal line, the space behind the postmedian line somewhat darker. Hindwing dark brown with yellowish fringe. Expanse of wings: 46 mm. Mexico (Tabasco), Panama (Chiriqui), Costa Rica.

dejecta. **M. dejecta** Schs. has likewise greenish-grey forewings, but with the usual black double dots on the ends of the veins, the double black transverse lines filled with yellowish ochre, the anterior one extinct below the cell, another fine dark line before the posterior line, so that it becomes threefold. Hindwing brownish-black, yellowish at the inner margin and fringe. Expanse of wings: 54 mm. Costa Rica.

euthymia. **M. euthymia** Schs. differs from the similar *innoxia* and *submarginata* in its colour and white fringe; forewing white, thickly strewn with brown sand-colour, both the brown transverse lines double, the posterior one only traceable; the brown subterminal line is also double, it forms but one crescent between 6 and 4 and is interrupted inwards on 3; the blackish-brown broken marginal line is distinctly bordered with white inside; fringe white, a black punctiform line before it. Hindwing dark greyish-brown, reddish-yellow at the inner margin, with a dark curved line at the anal angle. Fringe white. Expanse of wings: 51 mm. Santo Domingo, Peru.

caeca. **M. caeca** Dogn. Forewing lighter or darker slate-coloured, the black double transverse lines filled with brown, the posterior one bordered with brown also outside; white dusting before the oblique black marginal streaks, the ends of the veins are also white, finely bordered with black. Hindwing blackish, base and inner margin yellowish. Expanse of wings: 40—45 mm. South-Eastern Peru.

montana. **M. montana** Schs. is grey on the forewing, dusted with brown, with the usual double lines, the anterior one brown, the posterior one black bordered with ochre in its interior part, the exterior part brown distally bordered with grey, with a brownish shadow in the upper half behind it; yellow and black scales on the cross-vein, the inner margin shaded somewhat brownish. Hindwing brownish-black, light brown at the base and inner margin. The ♀ shows blacker transverse lines, the anterior one faded and shaded with black below the cell. Expanse of wings: 50 mm. Peru.

M. *sidata* Schs. is darker than *politioides*, intensely strewn grey and reddish-yellow, the transverse *sidata*. lines of the same course as in *politioides*, filled with a somewhat greenish colour; fringe yellowish. Hindwing dull brown with yellow fringe. Expanse of wings: 49 mm. Venezuela.

M. *thryeston* Drc. is allied to *sidata*, but the forewing is silvery white strewn with black, with a yellow *thryeston*. basal spot surrounded by black, the transverse lines black, scaled yellowish, fringe white. Hindwing black with yellow inner margin and fringe. Expanse of wings: 50 mm. Peru.

M. *limosa* Schs. has blackish forewings strewn with grey along the costal margin and apex, the trans- *limosa*. verse lines quite indistinct in the dark ground, only the submarginal line is somewhat more distinct; a short black longitudinal streak behind the cell. Hindwing whitish, dusted with black at the margins, with a small black anal spot. Expanse of wings: 48 mm. Brazil.

M. *submarginata* Schs. (= *julia* Drc.) (152 i). Forewing greenish-grey strewn with dark brown, lighter *submar-* grey at the base of the inner margin, the double black transverse lines of the usual course, the posterior line *ginata*. distally shaded with grey, small grey submarginal spots bordered with dark velvety brown inside. Hindwing black, inner margin and fringe ochreous. Peru.

M. *mochosema* Schs. Forewing reddish-olive strewn with blackish-brown, the vertical anterior transverse *mochosema*. line blackish-brown, twice interrupted on the veins, a double median line close behind it; a few black scales behind the white discal streak; the double subterminal line behind the fine postmedian line begins near the apex and is filled with dark olive between the costal margin and 6, and between 2 and 3; a feeble irregular shadow behind it; the brown marginal line bordered with white inside recedes below 6 and extends undulated to vein 2, from where it forms oblique marginal streaks. Hindwing brown with a double white-marked anal-angular line and white fringe. Expanse of wings: 41 mm. Teffé, Amazons.

M. *arida* Schs. (= *basifera* Rothsch.) (152 h, i). Forewing greenish whitish-grey, strewn darker, with *arida*. a broad dark brown basal area enclosing 2 blackish transverse lines; a postmedian and submarginal transverse row each of small roundish white spots scaled yellow and black outside. Hindwing whitish, inner and distal margins smoky grey, quite brown in the ♀. Guiana, Colombia, Bolivia.

M. *arenosa* Schs. Forewing dingy white, strewn with grey and light brown, especially at the costal *arenosa*. margin and in the median area, with a brown oblique basal shadow below the cell; dark brown lines at the cell-end and dusted reddish-brown lines between them are connected with a large brown costal-marginal spot before the apex, small brownish internerval spots on the margin, no transverse lines whatever. Hindwing scantily scaled, brown, yellowish-white at the inner margin and base. Expanse of wings: 33 mm. French Guiana.

M. *seitzi* sp. n. (152 i) is near to *arenosa*, but much larger; forewing white, strewn with brown, most *seitzi*. densely so at the costal margin and in the median area basally below the cell with a blackish-brown triangular spot extending obliquely to the inner margin, with several double blackish-brown notched fine transverse lines, one also in the middle; a dark brown reniform macula at the cell-end is edged with white on both sides; a large blackish-brown costal-marginal spot behind the postmedian line extends pointed to the apex and forms a dent downward distally above the uppermost radial branch; 2 large blackish-brown spots above the anal angle, regular submarginal lunar spots distally filled with brown. Hindwing brownish-grey. Described from 2 ♀♀, one from Paramaribo, the other from Bolivia, in Coll. SEITZ. Type in the Senckenberg Museum.

M. *polycarpa* Schs. is closely allied with *arenosa* Schs. Forewing white thickly strewn with reddish- *polycarpa*. brown, which is condensed to a dark shadow apically; subbasal line double, a grey spot behind it at the inner margin, both the transverse lines double, dark brown. the posterior line with long dents as far as the marginal line which is composed of black lunules, more of small spots towards the apex; fringe speckled white and brown. Hindwing reddish-brown, dark brown at the margin, fringe white. Expanse of wings: ♂ 34, ♀ 35 mm. Rio Purus (Brazil).

M. *phastioides* sp. n. (152 k) is easily recognisable. The pale yellowish ground of the forewing is *phastioides*. densely strewn with blackish-brown, producing an olive impression; the double subbasal line together with the treble antemedian line in the basal third of the costal margin down as far as the median line forms a quadrangular blackish-brown spot by denser strewing, this spot extending shadow-like through the lower half of the cell as far as behind the postmedian line; a short dark streak at the cross-vein, a fine strongly curved line behind it; postmedian line threefold, from near the apex in a straight line obliquely to vein 3, receding a little below it, and curved almost to the anal angle, whitish in the interior portion, distinctly filled with light blue between 2 and 4, the exterior portion filled with blackish-brown between 2 and 4 and 6 and the costal margin; subterminal area much lighter owing to the very scanty strewing, the margin itself darker again, containing a somewhat punctiform marginal line. Hindwing red-brown, cell and costal margin above it lighter, a dark double streak filled with whitish at the anal angle. Fringe whitish. 2 ♂♂ from Rio Putumayo, Mocoa, Colombia; February 1921, in the Berlin Museum (WERNER HOPP leg.).

rufipuncta. **M. rufipuncta** Drc. (152 i) is the most easily discernible species with silvery grey forewings with fine black double lines, large red-brown round spots, one at the base, one in the cell, two behind it and one at the anal angle. Hindwing greyish-black, yellow at the base and inner margin, fringe speckled yellow and black. Peru.

93. Genus: **Phastia** Wkr.

Extraordinarily near to the preceding genus, chiefly separated by the more slender, straightly porrect and not so thickly haired palpi and also more slender hairless legs. Costal margin of hindwing straight, distinctly convex at the base in the preceding species. No difference whatever in the neuration. Half a dozen of tropical species are known.

Type of genus: *P. basalis* Wkr.

- basalis*. **P. basalis** Wkr. (152 k). Forewing greenish olive with an oblique blackish stripe from the first quarter of the costal margin to the anal angle, strewn with reddish-brown below it, with a light round, dark-centred macula at the cell-end and a distally concave postmedian line. Hindwing brownish-grey. Colombia, Brazil.
- alcimede*. **P. alcimede** Drc. (152 k). Forewing dark brown, a reddish spot at the base and 2 yellowish transverse lines, a postmedian and submarginal row each of small greyish-white spots, the latter row containing black dots. Hindwing dark brown with somewhat lighter fringe. Panama to Ecuador, Colombia and Bolivia.
- duronio*. **P. duronia** Drc. (152 k) is light reddish-brown on the forewing, with a white subbasal line bordered with dark brown outside, a very oblique transverse row of black dots behind it from near the apex to the centre of the inner margin; a curved submarginal row of black dots edged with white inside. Hindwing dark brown with lighter fringe. Costa Rica, Panama.
- umbrata*. **P. umbrata** Schs. (= *rufolineata* Dogn.). Forewing light brown, shaded with grey basally, also at the distal margin above each vein; a round reddish-brown spot above the base of the inner margin, indistinct darker brown transverse lines proceed from the shaded lilac and grey costal margin, a whitish undulate-linear shadow before the margin. The whitish ground of the hindwing is densely dusted with lilac brown. Expanse of wings: 30 mm. French Guiana.
- ochreata*. **P. ochreata** Schs. looks quite different: forewing ochreous above the median vein and the lowest radial branch, violettish-brown below it with a grey submedian shadow; the base of the cell, the outermost costal margin and the two upper radial branches are violettish-brown. Hindwing smoky grey, darkest at the inner margin, the ends of the veins and a marginal shadow reddish-brown. Expanse of wings: ♂ 32, ♀ 36 mm. French Guiana.

94. Genus: **Euphastia** Dogn.

The only small species is similar to the preceding species, but the second palpal joint is somewhat more hairy; vein 5 of the forewing arises from the centre of the cross-vein, and 6 and 7 of the hindwing are not stalked, but arise from the same base, and the costal vein arises before the cell-end.

Type of genus: *E. nubila* Drc.

- nubila*. **E. nubila** Drc. (= *ophidera* Dogn.) (152 k). Forewing yellowish ochreous with a slight greenish tinge, a blackish transverse band at the base and another one beginning in the cell, bending distally above the inner margin and rising again subterminally, terminating at the cell-end in a thick black small round spot; subapically strewn with brown. Hindwing light brownish, darkened at the margin. Guiana, Colombia.

95. Genus: **Dugonia** Schs.

The only species has longer palpi with a smooth terminal joint, antennae of the ♀, which is only known so far, serrate, with ciliary tufts basally, then only ciliated as far as the middle. Hind tibia with 2 pair of long spurs. Forewing long and narrow, margin slightly undulate-dentate; veins 3 and 4 from the lower cell-angle, 5 from the centre of the cross-vein. Areole short, arising from the cell-end, 6 from the upper cell-angle, 7—10 from the end of the areole. Hindwing with a straight costal margin and a rounded apex; 4 and 5 from the lower cell-angle, 6 and 7 from the upper cell-angle, 8 arises before the centre of the cell.

- eliera*. **D. eliera** Schs. Forewing chestnut-brown, dusted with cinnamon-orange at the inner margin, expanded analwards as far as between 2 and 3, before which there is a white triangular spot and a white streak above it as far as the margin; double postmedian and subterminal rows of blackish-brown spots, and a brown oblique shadow from the cell to the apex; small white lunules subterminally between 5 and 1. Hindwing brown, cinnamon-orange at the inner margin and strewn with white and spotted black. Expanse of wings: 30 mm. French Guiana.

96. Genus: **Euxoga** *Mschlr.*

♂ antennae ciliated, the rather long palpi with thick but smooth hair, with a longer terminal joint. Forewing broad with a straight costal margin and indented distal margin as far as the upper median branch, then obliquely to the inner angle. Neuration not different from that of all the preceding species except the costal vein of the hindwing arising nearer at the centre of the cell.

Type of the genus: *E. argenteopunctata* *Mschlr.*

E. argenteopunctata *Mschlr.* (= *senilis* *Dogn.*) has brown forewings strewn with blackish, the two transverse lines marked by single rows of silvery white dots, the reniform macula is also represented by 4 small silvery spots arranged cross-like; the subterminal line is composed of a double row of white dots, the interior row being situate on the veins, the exterior one between them; a darker shadow extends before these two rows. Hindwing yellowish-grey, brownish at the margin. Expanse of wings: 34—41 mm. Dutch Guiana. *argenteo-punctata.*

E. amatura *Schs.* Head and thorax white, strewn with reddish-brown, abdomen brown above, white basally, at the end and beneath. Basal half of forewing light drab, strewn with brownish-black, more densely in the marginal area; subbasal line double, one antemedian and median line each, slightly separating below the cell, a white spot above vein 1; an olive, white-edged line at the cross-vein, continued above and below towards the base; the fine dark postmedian line is dentate, a light grey line behind it, with double black and white vein-dots behind it; then follows a dark brown shadow extending from 6 to the costal margin and from 2 to the anal angle; a large light grey spot at the apex and a similar lunular line before the margin. Fringe brown. Hindwing blackish-brown, lighter basally, with a white inner-marginal stripe. Expanse of wings: 30 mm. Amatura, Amazons. *amatura.*

E. pistacina *Dogn.* differs from *amatura* in the light green basal half of the costal margin and the somewhat deeper basal spot which is likewise light green, the distal half of the cell of the same colour; marginal area lighter reddish-brown, containing 4 black marginal spots, the white anal spot and the yellow strewing behind it are more or less indistinct. Expanse of wings: 37—39 mm. French Guiana. *pistacina.*

E. balba *Dogn.* (= *caudatula* *Schs.*) (153 a). Forewing brownish-white with a pink tinge, more purely white at the costal margin, spot-like white dusting in the centre of the margin, one brown spot each in the basal area and in the centre of the cell, and 3 white transverse lines. Hindwing reddish-brown with a white anal fold and a caudiform hair-tuft at the anal angle. French Guiana. *balba.*

97. Genus: **Goaxis** *Schs.*

Separated from the preceding genus merely by the margin not being smoothly edged but dentate, its concavity not beginning already at the apex but only at vein 6.

Type of genus: *G. singularis* *Schs.*

G. singularis *Schs.* (153 a) has brown forewings, strewn with blackish at the inner margin, the darkest in a triangular shape behind the base, with double dentate black transverse lines filled with lighter reddish-yellow, and a black discal streak bordered with white on both sides. Hindwing blackish-brown, fringe lighter. Brazil. *singularis.*

G. fuscifasciata *Dogn.* Forewing light reddish-yellow dusted with white, the transverse lines broken up into rows of dots, the posterior line double, an oblique shadow behind the yellowish-red cell-end streak, which is bordered with light, extends to the dent in the centre of the margin. Hindwing reddish-brown, blackened at the apex and margin. Expanse of wings: 22 mm. French Guiana. *fuscifasciata.*

G. fertilis *Dogn.* Forewing red-brown strewn with light violet; behind the white-edged discal spot follows a very large black ocellus, the centre and upper edge of which are strewn with violet; a strongly angled lilac line is on the margin. Hindwing blackish with a pink hue, and black and white fringe; a caudiform hair-tuft at the anal angle. Expanse of wings: 31 mm. French Guiana. *fertilis.*

98. Genus: **Maschane** *Wkr.*

Likewise allied to the two preceding genera, but the forewing lacks the angle at the distal margin which is very round, especially at the inner margin; costal margin very convex as far as beyond the centre, apex very pointed. Vein 5 removed almost up to the upper cell-angle, the rest of the neuration not very different from that of the preceding species, only vein 9 arises, separated from 8 and 7, from a little before the distal angle of the areole. Veins 3 and 4 of hindwing arise separately. Few tropical species are known.

Type of genus: *M. erratipennis* *Wkr.*

erratipennis. **M. erratipennis** Wkr. has violettish-grey forewings, dusted with reddish purple brown in the costal-marginal area and at the anal angle, the whole wing watered with violettish-grey striae which are bordered with whitish on the inside; the transverse lines are replaced by 2 broad faded shadowy bands, the anterior one extending from the first third of the costal margin to the base of the inner margin, the second from near the apex to the distal third of the inner margin, the inner margin between these two bands is shaded with blackish; a dark streak at the cell-end. Hindwing white. Expanse of wings: 26—29 mm. Brazil.

simplex. **M. simplex** Wkr. Forewing monotonously purple brown, similarly marked as *erratipennis*, but without the watery striations, the two shadowy bands much narrower and somewhat less oblique; indistinct internerval dots before the margin. Hindwing not purely white but with a slight grey hue, darkened at the margin. Described from Brazil. Expanse of wings: 28 mm.

rubricosa. **M. rubricosa** Dogn. Forewing yellowish-pink with a lilac tint above a black, white-strewn oblique line from the apex, chestnut-brown below this line, dusted with violet towards the base; a black subcostal spot before the first third of the costal margin, and a dot below it, from which an oblique band extends to the line which ends in a white subapical spot, 2 smaller ones below it. Hindwing red-brown, yellowish basally and at the costal margin, fringe yellowish. Expanse of wings: 26 mm. French Guiana.

leechi. **M. leechi** Drc. Ground-colour of forewing light reddish yellowish-brown, a dark brown line from the apex obliquely to the base of the inner margin, distally bordered with a lighter colour. Hindwing of the same colouring. Amazons. Expanse of wings: 34 mm.

frondea. **M. frondea** Schs. (= *costipuncta* Roths.) (153 a) lacks the oblique line; forewing light brown, warming into yellowish at the distal margin, dusted with violet at the base and median area, and at the costal and inner margins; a black dot at the cell-end; costal margin very convex, with a velvety brown broad stripe in its centre. Hindwing light reddish-brown, lighter towards the base. The species seems to be rather variable, particularly in the intensity of the more or less dark violet dusting. Expanse of wings: 34 mm. French Guiana.

99. Genus: **Rifargia** Wkr.

This genus is a parallel branch of *Heterocampa* (*Disphragis*) or *Malocampa*, almost nearer to the latter owing to the hair at the base of the hindwing beneath; the only mark of distinction is that the ♂ antennae are not pectinated but tuftedly ciliated. This genus also abounds in species and forms. A monography treating upon them will have to subdivide the genus into several subgenera. The genus contains many large species often of a beautiful colouring and marking, such as the *picta*-group.

Type of genus: *R. xylinoides* Wkr.

xylinoides. **R. xylinoides** Wkr. (= *cloelia* Schs.) is brownish-black on the forewing, tinged with moss-green at the costal and inner margins as well as behind the cell, with a black-edged reniform macula at the cell-end; both the transverse lines indistinctly double, the anterior one extending to the inner margin in three arches, the posterior one dentate and with black and white vein-dots which reoccur at the base of the fringe; a light brownish-yellow patch divides the apex from where it extends below the median vein almost to the base. Hindwing greyish-brown. Expanse of wings: 36 mm. Brazil.

mortis. **R. mortis** Schs. (153 a) is allied to *xylinoides* and was treated at last by its author as a synonym to *Disphr. gelduba* (p. 970). I had mentioned there that I consider it to be different, because in my opinion the ♂ of *gelduba*, which undoubtedly looks very similar, is to be distinguished by its pectinate antennae and to be placed to *gelduba*. Forewing dark blackish-grey, strewn with moss-green at the centre of the costal margin, with a velvety black cell-end streak; traces of darker transverse lines, the posterior one with white vein-dots; a light reddish-yellow shadow divides the apex, an indistinct dark submarginal shadow below it extends to the anal angle above which there is a black thick dot. Hindwing dingy white, strewn somewhat brown at the costal and distal margins. Expanse of wings: 33—35 mm. From Guiana to Argentina.

muscosa. **R. muscosa** Dogn. is near *mortis*; forewing greenish-grey, partly strewn with lilac grey, with the same transverse lines as in *mortis*, the anterior one more distinct, double, and likewise with white vein-dots; the light apical oblique streak is narrower and much longer, extending to the middle radial vein. Hindwing more purely white, only brownish at the costal margin and apex. Expanse of wings: 30 mm. Argentina.

morula. **R. morula** Dogn. also belongs to this group and has blackish-grey forewings extensively strewn with green basally, in the centre of the costal margin, in the distal half of the cell, submedianly and at the margin; all the markings very difficult to discover in the dark ground, the posterior transverse line marked by a double row of white vein-dots, the black cell-end streak distally dusted somewhat red-brown; black subterminal dots

bordered with white are at the anal angle and above it; *morula* is without the white vein-dots at the base of the fringe in the preceding species. Expanse of wings: 27 mm. Likewise from Argentina.

R. moha *Dogn.* (153 a) likewise resembles the colouring and marking of *D. gelduba*; grey with a green *moha*, and yellow admixture especially in the disc, a large yellowish oval spot behind the cell, distally bordered with black; a white subterminal spot is subanal, 2 irregular black lines above it. Hindwing blackish. Venezuela, Colombia, Bolivia.

R. occulta *Schs.* is larger than the preceding species, forewing blackish-brown, the veins strewn with *occulta*, black and light grey; a round spot at the cell-end is strewn with brown in the centre and finely surrounded with white, the fine black dentate postmedian line is feebly double; a light reddish-yellow spot at the apex contains a black streak, a light marginal shadow below it and black marginal lunae behind it. Hindwing blackish-brown, fringe yellowish. Expanse of wings: 54 mm. French Guiana.

R. onerosa *Schs.* is smaller than *occulta*, forewing darker violettish-black, partly mixed with moss- *onerosa*, green, especially at the base, distally bordered by a curved light line; transverse line dark brown, bordered with reddish-brown, the posterior line followed by a series of small dark brown shadowy spots, a dark brown ring filled with a lighter colour is at the cell-end; 2 red-brown subterminal streaks above the anal angle and in the centre, and a large reddish-yellow apical spot strewn with red-brown; small light red-brown spots before the undulate black marginal line. Hindwing violettish-brown with a dark anal spot and yellowish fringe. Expanse of wings: 45 mm. French Guiana.

R. phanero stigma *Dyar* (153 b) is allied to the two preceding species, but easily discernible by a round *phanero stigma*, white apical spot; forewing dark brown, more greyish in the median area, bordered by the double transverse lines which are filled with chocolate-brown; the elliptical discal spot is composed of an outer white ring divided into small spots, finely bordered with brown inside and filled below with a small ochreous spot; yellowish blotches are between the small subterminal white vein-spots. Hindwing as in the preceding species. British Guiana.

R. stellata *Schs.* is another large species with dark brown forewings, light brown between veins 2 and 4, *stellata*, and between 5 and 6, strewn with white on the veins and at the inner margin; a purple black spot behind the large discal spot which is strewn with yellowish-white and bordered with black and white; a fine white line extends from the white apical spot downwards. Hindwing dark brown with yellowish fringe. Expanse of wings: 54 mm. British Guiana.

R. indecora *Schs.* is a smaller species, forewing grey, darker in the basal half, with a reddish-brown *indecora*, spot below the base of the cell, and brown strewn in the cell and above it; behind the black cell-end streak follows a large diffuse black spot which is continued to the apex by blackish-brown shading; traces of a black undulate postmedian line. Hindwing blackish-grey. Expanse of wings: 32 mm. Dutch Guiana.

R. testaceata *Dogn.* is allied to *indecora*; the white ground of the forewing is strewn with reddish yellowish- *testaceata*, brown, more intensely in the distal half, with the same basal spot below the cell as in *indecora*, the similarly coloured antemedian line strongly dentate; the centre of the black reniform macula is strewn with grey, the grey subterminal band strongly dentate in the lower half. Hindwing blackish, fringe whitish. Expanse of wings: 32 mm. French Guiana.

R. discrepans *Schs.* Forewing dark drab with a round brown basal spot below the cell, traversed by *discrepans*, a dark brown, partly double line, the similar postmedian line is interrupted between the veins 2 and 3, accompanied below it on each side by a velvety brown side, with a red-brown shadow and an almost straight dark line in the upper half outside; one streak each above and below vein 5, and a velvety brown subapical luniform spot. Hindwing dark brown, lighter basally with a black and white anal spot. Expanse of wings: 47 mm. French Guiana.

R. litura *Schs.* (= *maeulata* *Dogn.*). Forewing light brown, strewn with dark brown, a blackish *litura*, spot below the base of the cell and black irregular undulate transverse lines; before the dark cell-end streak the lower cell-end is crossed by a blackish oblique shadow, 2 subterminal black spots below and above the centre between the black and grey spotted veins; the lighter undulate line is not strewn, round black internerval spots behind it, and double marginal dots behind these spots. Hindwing violettish-brown, darker at the margin, with a black and white anal spot. Expanse of wings: 51 mm. French Guiana.

R. tulira *Schs.* is somewhat similar to *litura*, strewn darker in the basal half, the anterior double *tulira*, transverse lines only distinct at the costal margin, the double almost straight median line filled with a lighter reddish-brown, dark spots before the postmedian line, not behind it, a large, light-edged irregular spot is at the cell-end, and the black marginal spots are replaced by a single marginal line which is slightly thicker only between the veins. Hindwing dark brown with a dark anal dot and light fringe. Expanse of wings: ♂ 45, ♀ 49 mm. French Guiana.

- sator*. **R. sator** Dogn. is near to *discrepans*, forewing light violettish-brown with black veins, the grey spot at the base of the cell is traversed by a black streak, a lighter reniform macula bordered with black inside is between the partly double transverse lines; the veins are partly dotted white on the transverse lines, a black subterminal streak below vein 2, a red-brown streak above it, red-brown clouding behind the cell, grey clouding above it, and a black subapical streak above the latter. Hindwing brownish, with a dark marginal band and a black and white anal spot. Expanse of wings: 39—41 mm. South-Eastern Peru.
- exarmata*. **R. exarmata** Dogn. is allied to *sator*, *discrepans*, and *tulira*, but more monotonously brown, with a slight violet shine at the inner margin, without the red-brown basal strewing and without the black subbasal streak of *sator*; an intense black streak at the anal angle, a white spot on the fringe behind it. Expanse of wings: 36—41 mm. French Guiana.
- rufidiscata*. **R. rufidiscata** Dogn. is very similar to *litura*, forewing brownish olive with 2 blackish-brown basal spots, black double dentate transverse lines, and a reddish-brown discal spot bordered with black; the postmedian line despatches on vein 6 an oblique shadow to the apex, enclosing a dentate line with white vein-dots; 2 dents of the postmedian line are closed on the veins 3 and 4 forming a ring-like figure; the light undulate line shows 3 bends. Hindwing blackish, fringe yellowish-white, a black and white anal spot. Expanse of wings: 46 mm. East Colombia.
- incisura*. **R. incisura** Dogn. (= *terebroides* Rothsch.). The brown forewing is grey and strewn with green at the costal margin, postdiscally, in the centre of the inner margin and subterminally in 2 spots, with 4 double transverse lines, the two posterior ones of which are strongly incised between the veins and 3; a light line before the fine black subterminal line, the former almost straight in the upper half, dentate below it. Hindwing brown with a black and white anal spot. Expanse of wings: 57 mm. French Guiana.
- versuta*. **R. versuta** Dogn. Forewing violettish-brown, yellowish ochreous in a large triangular discal spot and above it at the costal margin in an oblong spot which is extended towards the apex, with single black dentate transverse lines, 3 somewhat darker undulate lines behind the postmedian line, the distal subterminal one of which is bordered with lighter outside. Hindwing brown. yellowish basally. Expanse of wings: 48 mm. Amazons.
- demissa*. **R. demissa** Schs. (153 b). Forewing greenish whitish-grey, intermixed with red-brown and black scales, with dark brown double dentate transverse lines, 2 small black spots behind the postmedian line below the middle, 3 similar spots above them, the latter extending obliquely to the apex; 2 oblique brown lines at the cell-end in a brown median shadow, a reddish-brown subterminal shadow before a black interrupted lunular line. Hindwing greyish-black, with lighter hair at the inner margin. Expanse of wings: 41 mm. French Guiana.
- brioca*. — f. **brioca** Schs. differs in a coherent black band behind the postmedian line being somewhat dentate outside. Expanse of wings: 45 mm. British Guiana.
- auscharia*. **R. auscharia** Schs. is easily recognisable by the punctiform lines in the distal half of the forewing; forewing white strewn with black and brown, more olive grey in the postmedian area; the double brown transverse lines are very indistinct, the posterior line with blackish-brown vein dots, 2 more rows of dots behind them, the marginal line is also punctiform; fringe white with brown vein-dots. Hindwing white, dusted with smoky grey, veins and margin darker. Expanse of wings: 42 mm. Venezuela (Valera).
- possida*. **R. possida** Schs. Forewing from the base to the cross-vein and from there obliquely to the anal angle white, scantily strewn with black, brownish sand-coloured in the apical area, strewn with white in the marginal area; the anterior and posterior transverse lines are double, dentate, a quadrangular brownish spot strewn with white and edged with blackish-brown between the anterior line and the subbasal line at the costal margin, extending into the cell; a blackish-brown median line is united with a black cell-end streak; a blackish-brown lunular line at the margin; fringe with dark vein-dots. Hindwing white with a small dark anal spot. Expanse of wings: 39 mm. Porto Velho (Amazons).
- extranea*. **R. extranea** Schs. (153 a). Forewing grey strewn with dark brown, so that only the basal third of the costal margin and the distal margin remain grey, the inner margin being darkest as far as the postmedian line; the anterior black transverse line is threefold, the posterior one brown, filled with grey, followed by a brown shadow with velvety brown internerval streaks which become stronger towards the costal margin, and are absent altogether in the inner-marginal third. Hindwing whitish with a broad black costal margin and distal margin and brown inner-marginal hair. This description refers to the ♀; the ♂ probably belonging to it has lighter grey forewings strewn with yellow and white at the inner margin, at the transverse lines and at the cell-end. Expanse of wings: 38 mm. French Guiana.
- notabilis*. **R. notabilis** Schs. Forewing brownish ochreous with a greenish-grey costal margin and a similar oblique band from the base of the cell to the inner margin; distally bordered by a fine brown line; the space behind the cell, which is closed by a black streak, is grey and contains 2 undulate lines, a red-brown postmedian line is visible below this dark grey area; a fine velvety black submarginal line, its lower half being distally removed as far as the margin. Hindwing whitish with a smoky black costal margin and inner margin. Expanse of wings: 44 mm. French Guiana.

R. corda Drc. (= *grisca* Schs.) (153 b) has silvery grey forewings, the costal margin shaded brown, *corda*, with a small black basal spot and dark brown double transverse lines, the posterior one transformed into a broad brown band before which there are single deep black spots. Hindwing whitish with a broad dark grey marginal band. Expanse of wings: ♂ 40, ♀ 43 mm. Colombia.

R. phasma Dogn. Forewing greenish ochreous (the fresh specimen probably of a purer green), the *phasma*, basal half of the inner margin black with fine black transverse lines composed of deep lunae; the distal half of the cell and the postdiscal area behind it darkened by extensive black shading, a black subterminal shadow reaches neither the costal margin nor the inner margin. Hindwing yellowish-white, blackened at the costal and inner margins, grey at the distal margin. Expanse of wings: 38 mm. Brazil and Argentina.

R. spontiva Dogn. (153 b) is a beautiful species coloured green and red-brown, the greenish-white *spontiva*, ground traversed by numerous partly olive black partly red-brown dentate transverse lines, a very broad dark olive green oblique band between them extends from the first quarter of the costal margin to the anal angle before which it disappears; a still darker triangular spot behind the cell at the costal margin almost to the apex; the 3 distal postmedian lines are broken up into dots, the ground between them partly filled with red-brown. Hindwing blackish, the anal spot parted by white. French Guiana, Colombia.

R. elgiva Schs. (153 b) is a large species, greyish-brown mixed with black, the distal half of the forewing *elgiva*, of a somewhat purer brown, with dark veins and fine blackish-brown double transverse lines and basal ray; the dark ring-macula and reniform macula are surrounded by white; the undulate line is a dark dentate shadow. Hindwing reddish-brown, the black anal spot parted by white. Expanse of wings: 55 mm. French Guiana.

R. imitata Drc. is a strange insect exactly like the well-known *Proelymiotis aequipars* (144 g); forewing *imitata*, light greenish-grey, broadly dark brown in the basal half, distally bordered with black, with a small dark brown spot near the apex, one above the anal angle and a somewhat larger quadrangular one between veins 3 and 4; black submarginal streaks. Hindwing greyish-brown, darkened at the margin, with a black anal spot. Trinidad.

R. mistura Schs. (= *cossoides* Roths.) (153 c) is one of the largest species; forewing greenish-grey, *mistura*, mixed a little with brown, deep chocolate-brown in the basal third in the costal-marginal half, and with a similarly coloured apical spot, with more or less distinct double brownish transverse lines and a fine black subterminal line; whitish brightening postdiscally below the apical spot. Hindwing dark brown, fringe lighter. Expanse of wings: 67 mm. Guiana, Brazil (Amazons).

R. albidivisa Dogn. is very closely allied to *mistura*, separated by a more curved double anterior trans- *albidivisa*, verse line, with more white dusting behind it, a merely rounded reniform macula which is entirely reniform in *mistura*, 2 white-strewn spots before the posterior transverse line at the inner margin. This species described from French Guiana is also somewhat smaller. Expanse of wings: 64 mm.

R. lemoulti Schs. (153 c) is somewhat similar to the preceding species, but the dark basal part is replaced *lemoulti*, here by a light, reddish-yellow area distally bordered by red-brown lines and longitudinally traversed by fine red-brown lines; apex light reddish-brown with deep black longitudinal streaks. Hindwing dark brownish-grey with light reddish-yellow fringe. Expanse of wings: ♂ 63, ♀ 76 mm. Guiana, Brazil.

R. culpata Schs. is still larger than *lemoulti* and very similar; distinguished by lighter reddish-brown *culpata*, hindwings with a dark median line distally bordered with reddish-yellow, and a broad darker brown subterminal shadow; forewing darker grey, the basal third darker, more brownish, the reniform macula at the cell-end is larger, the red-brown apical spot with a darker border without black streaks in it. Expanse of wings: ♂ 69, ♀ 83 mm. Costa Rica.

R. biplaga Roths. (153 d) is a very large easily recognisable species from the *lemoulti*-group, similarly *biplaga*, marked, but the forewing is mixed with lighter and darker brown and exhibits 2 very characteristic greyish-white spots at the inner margin, separated by the median shadow; a reddish-brown spot at the base of the inner margin, and a long black streak at the apex. Hindwing dingy brown with a darker, distally lighter median shadow. Peru, Bolivia.

R. everiti Schs. is also a very large species. Forewing whitish, strewn with reddish-brown and *everiti*, ochre, a black irregular spot at the base of the costal margin; transverse lines black, the anterior one double, connected with the basal spot by a black spot below the cell, the cell above it whitish; the oval white reniform macula is narrow, bordered with blackish-brown; a reddish-brown subterminal shadow below 4 extends to the margin and anal angle; a thick black oblique streak extends from the postmedian line towards the apex. Hindwing brownish-black with an indistinct postmedian line and a black and white anal spot. Expanse of wings: ♂ 65, ♀ 80 mm. French Guiana.

- impexa*. **R. impexa** *sp. n.* (153 c). Forewing yellowish-grey strewn with black, the larger basal part as far as the very large reniform macula and below it almost quite black, so that only the area of the reniform macula, the subterminal and marginal areas as well as the inner margin remain dingy greyish-brown; the markings in the basal part are quite extinct; the reniform macula shows inside above a roundish projection in the cell, producing the shape of a heart or trefoil-leaf, at its interior edge there is a Y-shaped black mark, and a : -shaped mark at its exterior edge, the centre between these two lines filled with reddish-brown; the costal margin above it is likewise light, traversed by 2 very oblique black lines the distal one of which is connected with the pointed dents of the postmedian line behind which there are black and white vein-dots; the marginal area shows traces of a light undulate line clouded blackish on both sides. Hindwing dark brownish-grey, fringe light. Described from a ♂ from Paramaribo; type in the Senckenberg Museum.
- nugax*. **R. nugax** *sp. n.* (153 c) is very similar to *impexa* in the marking, but the forewing is red-brown, the inner margin, the distal cell-end and an oblique shadow from there to the margin between the veins 2 and 3, as well as the margin behind the whitish dentate subterminal line are shaded blackish; the reniform macula shaped like a trefoil-leaf and the costal margin above it are greenish-white; the fine black transverse lines are distinct here, the anterior one indistinctly double, the posterior one distinctly double, forming an acute angle between veins 4 and 5 towards the reniform macula; a red-brown longitudinal stripe near the anal angle contains a black streak. Hindwing greyish-brown, darker at the margin, yellowish at the base, fringe yellowish-white. From a ♂ from Brazil, Coll. SEITZ in the Senckenberg Museum.
- albidula*. **R. albidula** *Dogn.* is a smaller species very similar to *Chadisra infanta*. Forewing silvery white with a black basal spot and 3 blackish-brown transverse lines, a large brown triangular spot behind the foremost line at the inner margin, a large costal-marginal spot behind the postmedian line down to the centre of the wing, enclosing darker internerval streaks. Hindwing lustrous white with a small anal spot. The ♀ is more intensely strewn with brown and has a brown angular cell-end band and blackened hindwings. Expanse of wings: ♂ 34, ♀ 42 mm. French Guiana.
- myconos*. **R. myconos** *Schs.* (= *pupula Dogn.*) (153 d). Forewing light grey with 3 irregular darker basal lines and a V-shaped black line in the cell; behind the double postmedian line follows a series of small black internerval spots, a large spot of dense black dusting is before the black submarginal line. Hindwing whitish in the basal half, dark grey distally. Colombia, Brazil.
- praerupta*. **R. praerupta** *Dogn.* is near *myconos*; the white forewing is strewn with brown with brown double transverse lines and a brown reniform macula surrounded by black; subterminal internerval dots are removed farther inwards between the veins 4 and 6 and distally shaded with brown; a spot of brown strewing is also behind the postmedian line at the costal margin. The ♀ is more intensely marked. Hindwing as in *myconos*. Expanse of wings: ♂ 39, ♀ 42 mm. French Guiana.
- condita*. **R. condita** *Schs.* (= *presbytica Dyar*) (153 d). Forewing white strewn with black in the basal third, distally bordered by a straight black line which is double below the cell, and traversed by a black line which is double at the costal margin. Forewing distally light brown, darkened towards the apex, the reniform macula surrounded with black, and with a double red-brown postmedian line behind which there are large black spots in the upper two thirds. Hindwing white with a black marginal band. Guiana.
- cassandra*. **R. cassandra** *Schs.* (= *longula Drc.*) (153 d). The white forewing is strewn with grey and light brown, the veins interruptedly striped black, with rather indistinct double grey transverse lines and a large red-brown spot at the cell-end, edged and traversed by dark lines; subterminal line whitish, bordered with red-brown in the upper half outside. Hindwing white with a dark grey marginal line and blackish hair at the inner margin. Venezuela, Colombia.
- felderi*. **R. felderi** *Schs.* (153 d) is an extremely common and widely distributed species with white forewings, very scantily strewn with black, with fine double dentate transverse lines, the reniform macula surrounded with black; behind the postmedian line there are small more or less distinct black internerval spots in a red-brown subterminal band. Hindwing white with a black anal spot. Mexico to Peru.
- bichorda*. **R. bichorda** *Hmps.* is probably a somewhat larger insular form, more densely strewn with brownish and without the red-brown subterminal band. The white hindwing is strewn with brown at the margin in the only ♀ described. Expanse of wings: 46 mm. Nassau (Bahamas).
- haitia*. **R. haitia** *Schs.* is somewhat similar to *bichorda*; forewing light drab, white strewn with brown at the costal margin, white with black strewing basally below the cell; both the transverse lines double, brown and black, the posterior one very fine and scarcely darker than the ground, a large erescent surrounded by black is at the cell-end; subterminal shadow brownish, double in its upper half. Hindwing white, narrowly brownish at the margin. Expanse of wings: 35 mm. Haiti.

R. nebulosa Schs. (153 d) is a rather variable species very closely allied to the preceding ones; forewing *nebulosa*. greyish-white, the disc lighter and scantily strewn with brown, with the same lines as in *felderi*, and brown dusting behind the postmedian line especially towards the costal margin. Hindwing white with a grey inner margin and distal margin. The ♀ is greyer with a brown costal spot at the base and grey hindwings. Mexico, Costa Rica. — f. **medioclara** Schs. which may be a distinct species has almost black forewings with a white area at the cell-end and a blackish shadowy stripe behind it in the cell-end. Hindwing white with narrow black veins and margins. Costa Rica. *medioclara*.

R. lineata Drc. (153 e) is probably one of the most common *Notodontidae* of a very vast range; it looks *lineata*. rather much like *felderi*, but it is much larger and especially the median area is more mixed with brownish, the posterior transverse line quite red-brown, close behind it follows an almost straight black line behind which there is a black notched shadow, a large white spot below it and reddish-brown strewing above the anal angle. Hindwing yellowish-white with a broad grey marginal band. Florida and Mexico to Brazil.

R. distinguenda Wlr. (= dubia Möschlr.) (153 e) is likewise very common and widely distributed, *distinguenda*. similar to the preceding species; forewing greyish-white, quite similarly marked, but more intensely strewn, the double transverse lines finer, often hardly noticeable, the basal area more or less brownish, with fine black internerval streaks subterminally. Mexico to Brazil.

R. dissepia Schs. is very closely allied to *distinguenda* and may be a form of it; forewing white, densely *dissepia*. strewn with light brown, the anterior transverse line is absent, the posterior one only single, a brown median shadow before it; subterminal line whitish, dentate, some black streaks behind it in the upper half and above the anal angle. Hindwing white with a broad black margin. The median area below the cell and a shadow at the cell-end are blackish-brown in the ♀. Expanse of wings: 45—47 mm. Costa Rica.

R. guianensis Schs. Forewing silvery white strewn with dark brown and similar markings; one small *guianensis*. triangular spot each at the bases of the costal margin and inner margin, traversed by an oblique dentate line, 5 costal-marginal spots between the centre and the apex; the centre is crossed by a fine partly double line before and behind which the strewing is denser; a velvety brown postmedian line is dentate only in the lower half, dark streaks behind it towards the costal margin, and a fine undulate line behind them. Hindwing white, broadly dark brown at the inner margin, narrowly at the distal margin. Guiana.

R. bianca Schs. (153 e). Forewing white, scantily strewn with brown, broadly light brown at the *bianca*. apex, a similar small spot also at the inner angle, the median and distal transverse lines very indistinct, 2 fine dark lines at the cell-end; 2 parallel black lines from the base of the costal margin to the first quarter of the inner margin, an almost straight thick black line is before the margin with small black internerval spots behind it. Hindwing white with blackish veins. Brazil.

R. apella Schs. (153 e). Forewing light brown with a large white irregular triangular area in the centre, *apella*. enclosing a black ring at the cell-end; transverse lines black, the submarginal line being most distinct. Hindwing brownish-white, dark brown at the distal margin. Brazil, Colombia.

R. cinga Schs. is very similar to *apella*; forewing silvery white strewn with grey and fine double black *cinga*. transverse lines and reniform macula; a broad reddish-brown oblique shadow traverses the median area from near the base of the costal margin to the inner margin at the posterior transverse line which extends down almost straightly and only shows 2 outward bends above the inner margin; marginal area iridescent reddish-brown dusted with white and with a black subterminal line the dents of which in the lower half extend to the margin. Hindwing reddish-brown. Expanse of wings: 54 mm. British Guiana.

R. causia Schs. (= titus Koehler) (153 e). Forewing white in the basal half and in an area near the *causia*. distal margin, the rest light brown, strewn with grey here and there and separated from the white by a black line; 2 short black parallel streaks behind the cell, and a very angular submarginal line, the veins of the marginal area black. Hindwing white with a brown anal streak. Brazil.

R. tethys Schs. Forewing dark grey with brownish transverse shadows and black transverse lines. *tethys*. the interior one double, the distal one single; a yellow spot bordered with black is at the cell-end, and black internerval spots edged with yellow inside are before the margin, a white crescentiform apical spot at the costal margin, yellow vein-dots on the base of the fringe. Hindwing brown, yellow at the base. Expanse of wings: 45 mm. Brazil (Rio de Janeiro).

R. brunnea Mschlr. Forewing red-brown, dusted with a lighter reddish-yellow along the costal margin *brunnea*. and below the median vein and from there between the veins 5 and 6 to the margin; both the transverse lines fine black, the anterior one forms 3 bows to the inner margin, the posterior one is double, dentate, removed considerably inwards between the veins 3 and 2; the veins behind it are black strewn with white; a large whitish reniform macula at the cell-end, its centre filled with reddish-brown, and finely surrounded with black, a thick black longitudinal streak extends from it outwards: undulate line light, dark brown shading before it. Black

double dots are before the margin in the interspaces. Hindwing brownish-grey, fringe yellowish-white. Guiana.

chocotoa.

R. chocotoa Dyar is near *tetys* and has monotonously chocolate-brown forewings, shaded somewhat blackish in the basal area; the two transverse lines are indistinctly double, the anterior one forms 3 bows, the posterior one is dentate on the veins, with black and white vein-dots behind it; a dark streak at the cell-end, somewhat lighter behind it; instead of the undulate line there are small indistinct blackish spots between the veins, each with a light halo on the outside; black oblique internerval streaks before the margin. Hindwing brownish-grey, lighter yellowish towards the base, long yellowish hair at the inner margin. Fringe yellowish-white. Expanse of wings: 66 mm. Colombia.

grandi-macula.

R. grandimacula Dogn. Forewing silvery grey finely strewn with greyish-brown and with double brown dentate transverse lines, the anterior one and posterior one uniting submedianly; a strong black crescentiform streak is at the cell-end, a broad blackish shadow behind it extends to the postmedian line and appears brownish towards the costal margin, fringe speckled white and brown. Hindwing blackish, spotted black and white at the anal angle. Expanse of wings: 42 mm. French Guiana.

picta.

R. picta Schs. (153 f) is the chief representative of a beautiful group of more variegated species; forewing violettish-brown mixed with grey, more reddish-brown at the costal margin, the two colours separated by a broad white stripe above the inner-marginal vein, which stripe does not extend to the margin and is bordered with black above and with olive below; a large light postcellular area is interrupted by a broad grey stripe bordered with black above and below; the postmedian line is shaded with olive. Hindwing whitish with brown veins and marginal line, brown inner-marginal shading and a dark inner-marginal spot. Guiana, Colombia.

intermedia.

R. intermedia Rothsch. (153 f) is intermediary between *picta* and *merita*; forewing reddish cinnamon with a broad reddish-brown longitudinal band to the centre of the margin with a pink tint, the longitudinal band above the inner-marginal vein reddish-yellow, more greyish outside. Hindwing reddish-yellow, brownish at the margin. The ♀ is larger with darker hindwings. Venezuela.

merita.

R. merita Schs. Forewing violettish-brown below the inner-marginal vein, olive above it, with a short white basal ray below the cell; a broad light violet band extends from the first quarter of the costal margin to the centre of the margin and turns darker distally, the distal three quarters of the costal margin above it are broad dark violettish-brown with 2 black lines in it; the fine postmedian line is double. Hindwing brown, blackish at the distal margin with a fine reddish-yellow line in it. Expanse of wings: 52 mm. British Guiana.

variegata.

R. variegata Dogn. differs somewhat from the diagnose of the genus in the antennae being set with lamellae. Forewing covered with scales of various colours, white, yellow and green at the base, then follow on the lilac and green ground 3 black parallel lines, the costal margin above the lilac and pink cell is white, the space below the cell lilac and green like the space behind it, only admixed with white at the margin; the black postmedian line is partly double, traversed by the black veins. Hindwing yellowish-white, brownish at the margin. Expanse of wings: 44 mm. Brazil (Novo Friburgo).

castrena.

R. castrena Jones. Forewing yellowish ochreous, dusted with red-brown and blackish, red-brown in the basal area and at the cell-end and behind it, with double dark dentate transverse lines, the posterior one filled with a lighter colour; a subterminal row of small reddish-brown luniform spots, 2 small black luniform spots before them in the lower half; an intense black streak at the cell-end connects 2 very dark shadows at the costal margin and below the cell. Hindwing yellowish-brown. Expanse of wings: 40 mm. Brazil (Castro, Parana).

rothschildi.

R. rothschildi n. nom. (= *muscosa* Rothsch. nec Dogn.) is an insect with very remarkably narrow wings, the generic position of which is not quite certain. Forewing greyish-green, watered black, pinkish-brown in the median area with double dentate black transverse lines, ring-macula and reniform macula, and a darker triangular apical spot. Hindwing brownish orange at the base as far as the inner margin, dull brown outside. Head and collar chestnut-red like the first two abdominal segments. Expanse of wings: 53 mm. Surinam.

100. Genus: **Grafiria** nov.

I establish this genus for a very remarkable insect described as *Rifargia*, from which it differs chiefly in the longer palpi with a rather long drooping beak-shaped or snout-shaped terminal joint. Wings very long, narrow, distal margin of forewing concave in the lower half, the slender abdomen projects considerably beyond the short narrow hindwings. The origin of vein 5 of forewing is removed down to the centre of the cross-vein, vein 6 arises right behind the beginning of the areole, not from its centre. Hindwing as in *Rifargia*.

Type of genus: *G. steinbachi* Rothsch.

G. steinbachi *Rothsch.* (= *speciosa* *Schs.*) (153 f). Forewing red-brown, mixed with light grey and *steinbachi*. greenish in the inner-marginal area and at the distal margin, the two colours bordered by a jet-black, inwardly faded line which forms 3 pointed dents outside and reaches the distal margin below the apex on the lowest subcostal branch; a feeble blackish longitudinal shadow extends through the lower half of the cell to the black line; the transverse lines are marked by single black, distally whitish dots, two of which are also in the cell one above the other. Hindwing whitish with a smoky brown marginal line and inner-marginal hair. The ♀ is much larger, of a duller colouring and thinly scaled. Bolivia, Amazonas, South Brazil.

101. Genus: **Afilia** *Schs.*

♂ antennae pectinated, ♀ plain. Palpi very short. The long narrow forewing lacks the arcole as in the following genera, for which reason vein 6 arises with 7—10 on a joint stalk. The costal vein of the hindwing arises nearer at the base, vein 6 arises with the subcostal vein from the same basis without a stalk. Only 2 species:

Type of genus: *A. cinerea* *Schs.*

A. cinerea *Schs.* (153 f) is an insignificant grey insect strewn with black, with fine indistinctly double *cinerea*. transverse lines which are mostly bordered with reddish-brown, and a distinct black lunar streak at the cell-end; small blackish undulate-linear spots are traceable, a fine black submarginal line is straight in the upper half, scalariformly interrupted below. Hindwing dingy white, greyish-brown in the ♀. The basal part is occasionally filled with brown. Mexico.

A. oslari *Dyar* (= *moqui* *Barnes*) is very similar, but much more intensely marked black, the transverse *oslari*. lines slightly bordered with reddish-brown on the averted sides, a broad triangular darkening before the anterior one at the costal margin. Hindwing white, very feebly smoked at the apex and distal margin. Arizona.

A. venadia *Schs.* Head and thorax brownish mixed with white, abdomen reddish cinnamon, more *venadia*. orange at the base. Forewing whitish scantily strewn darker at the base, costal margin and median area, the antemedian and marginal areas reddish-brown; the fine transverse lines are double, blackish-brown and brownish cinnamon; subterminal line dentate, interrupted on the veins. Hindwing white, dusted with reddish-brown. Expanse of wings: ♂ 28, ♀ 30—39 mm. Venadio (Mexico).

A. purulha *Schs.* Body like that of *venadia*, but forewing more monotonously grey, the subbasal and *purulha*. anterior transverse lines double, black, the antemedian line removed almost into the centre, connected with subbasal line by a black streak, the posterior line more brownish and more spotted. Hindwing purely white. Expanse of wings: 38 mm. Guatemala (Purulha).

102. Genus: **Scevesia** *Dyar.*

Distinguished from the preceding genus by more strongly pectinated antennae of the ♂, longer erect densely hairy palpi with a straightly porrect terminal joint. Vein 5 of forewing removed up near to the upper cell-end, the stalk of 6 with 7—10 very short. Hindwing as in *Afilia* except the vein 5 being nearly quite absent. Only 1 species:

Type of genus: *S. broidricci* *Dyar.*

S. broidricci *Dyar.* Forewing monotonously dark grey with a white, black-edged luniform spot at the *broidricci*. cell-end. Fine black subterminal internodal dots and a few small irregular blackish spots in the basal half. Hindwing smoky grey. Expanse of wings: 47 mm. Mexico (State of Hidalgo).

103. Genus: **Lobeza** *Herr.-Schäff.*

A well characterized genus of similar large species of a mostly whitish colour with strongly notched transverse lines. The ♂ antennae are shortly pectinated to the tips, the short hairy palpi erect, the strong abdomen tufted laterally. Vein 5 on the broad forewing arises from the centre of the cell, 6 from the upper cell-angle. The costal vein on the hindwing is connected with the centre of the cell by a short veinlet. Most of the numerous species are very difficult to separate.

Type of genus: *L. aglone* *Herr.-Schäff.*

L. aglone *Herr.-Schäff.* (153 g) is probably one of the largest species, the white forewing scantily and *aglone*. coarsely strewn with black, the double strongly notched transverse lines bordered somewhat rusty brown on the averted sides. Hindwing white. Brazil.

L. lateralis *Wkr.* resembles *aglone*, but it is much smaller, the forewing more densely strewn, the *lateralis*. transverse lines more distinct, deeply notched, strewn with yellowish on the averted sides; at the cell-end

there is a streak strewn with yellowish on both sides; oblique black fine streaks before the margin are scalariformly arranged below each other. Hindwing white, with yellowish hair at the inner margin, and with a fine black marginal line. Abdomen yellow above, with strong deep black lateral lines. Brazil.

gilberta. **L. gilberta** Schs. Head and thorax greyish-white, abdomen cinamon-brown with white dorsal spots, anal ring whitish, ventrum white, with drab bands. Forewing white, strewn with blackish-brown, very little in the median area; anterior transverse line fine, dark, with a few reddish-yellow scales, interrupted inwards below the median vein, then extending to the centre of the inner margin; cross-vein purely white with a dark dot in the lower cell-angle; postmedian line fine, with chestnut-brown scales, double below 3; fringe slightly scaled dark only at the ends of the veins. Hindwing white with a fine dark median line with vein-dots and a faint dark postmedian shadow. The ♀ is more densely strewn dark with more distinctly marked lines, the fringe spotted dark between the veins. Marginal half of hindwing dusted with brownish sand-colour. Expanse of wings: ♂ 58, ♀ 70 mm. French Guiana.

huacamaya. **L. huacamaya** Schs. Head and thorax white and blackish-brown, metathorax black mixed with orange; abdomen white with drab segmental lines, ventrum reddish-yellow. The white forewing is scantily strewn with black, the fine reddish-orange antemedian line strewn with black, almost touching the median line at the inner margin, a small ring at the cross-vein before the median line; the postmedian line is composed of blackish-brown lunules, a purer white area is before it, an orange ochreous parallel line behind it, blackish-brown and orange strewn behind this line as far as the whitish subterminal area. Hindwing white, suffused with brownish in the cellular spaces. Inner margin reddish, the veins and median line brown. Expanse of wings: ♂ 60, ♀ 83 mm. Peru (Rio Huacamaya).

petropolia. **L. petropolia** Schs. resembles the ♀ of *huacamaya*, the brown abdominal bands interrupted dorsally. Forewing white, strewn with black, more densely so subterminally; the anterior transverse line ends behind the centre of the inner margin; a small purely white spot in the lower cell-angle; fringe with large black spots; marginal line thickend on the veins, interrupted in *huacamaya*; hindwing brownish with a dark marginal line, broad white costal margin and fringe. Expanse of wings: 85 mm. Brazil (Petropolis).

maronia. **L. maronia** Schs. Front body white, collar and tegulae very little intermixed with brown; abdomen brownish-grey above with white segmental lines, white beneath. Forewing white, scantily strewn with black and brownish, a purely white area before the postmedian line; anterior transverse line doublé only at the costal margin, contiguous with the indistinct orange ochreous median line at the inner margin; a dark streak at the cross-vein; postmedian line double, the interior part blackish-brown, the exterior part lighter, more deeply bent inwards between 2 and 3, undulate-dentate; subterminal line white, marginal line dark. Hindwing brownish, white at the costal margin. Expanse of wings: ♂ 68, ♀ 85 mm. French Guiana.

venica. **L. venica** Schs. Anterior body white intermixed with brown, abdomen brown with reddish-cinnamon segmental lines, white beneath. Forewing white scantily strewn with blackish-brown, the blackish-brown double antemedian line interrupted inwards below the median vein, cross-vein white; the feeble median line forms distal dents on the veins; postmedian line black at the costal margin, double, deeply dentate at the inner margin, the exterior part below very indistinct, brownish ochreous. The white hindwing is suffused with brown, with a dark median line. Expanse of wings: 58 mm. Venezuela (Merida).

rhenia. **L. rhenia** Schs. is the only species of the *aglone*-group with purely white hindwings. Anterior body as in the preceding species, abdomen reddish-cinnamon above with whitish segmental lines, only the first and last segment white, ventrum white. Forewing white, scantily strewn with blackish-brown; anterior transverse line feeble in the ♂, stronger in the ♀, double at the costal margin, vertical and somewhat punctiform as far as below the cell, then somewhat undulate to the inner margin towards the median line; cross-vein white; postmedian line undulate-dentate, double only in the ♀; ♂ without a marginal line which is fine dark in the ♀. Hindwing white. Expanse of wings: ♂ 62, ♀ 84 mm. Colombia (Muzo; Medina).

medina. **L. medina** Schs. (153 g). Anterior body brownish-grey, metathorax with white tufts which are bordered with brown and orange. Abdomen white with brown subdorsal spots. Forewing white, the antemedian area strewn with blackish-brown excepting the base of the inner margin; anterior transverse line blackish-brown, spotted from the costal margin to below the cell, scaled orange below that; median area scarcely strewn at all; postmedian line composed of small spots, strewn with olive brown behind it, most densely so at the said spots; marginal line fine, fringe white. Hindwing white, base and inner margin reddish-yellow, a brown line extends from the costal margin to the anal angle. Expanse of wings: 67 mm. Colombia.

arnoula. **L. arnoula** Schs. Thorax white and light brown, collar darker brown. Abdomen light brown above with darker bands, whitish beneath. Forewing white, strewn with chestnut-brown, a subbasal spot at the costal margin, transverse lines red-brown, strewn with orange, the anterior line extends to the centre of the inner margin, a feeble lighter line behind the exterior line; a black dot in the lower cell-angle; a broad white subterminal band. Hindwing brownish cinnamon with a slightly darker median line. Fringe white, brownish at the anal angle. Expanse of wings: 65 mm. Peru (Carabaya).

genebrarda. **L. genebrarda** Schs. (153 f). Anterior body white, scantily intermixed with darker, collar brown, bordered with white. Abdomen brown above, intermixed with orange, the 2 last segments more white. Forewing white,

strewn with red brown, the lines composed of black, red-brown, and orange scales, the posterior line double, the interior part thicker, distally angled on vein 3, then vertical to the inner margin; a small blackish-brown spot at the cross-vein, a red-brown dot above it, a darker shadow behind it; traces of a whitish subterminal line; a dark lunular line at the margin is thickened on the veins. Hindwing light reddish-yellow and dusted grey from the base to behind the dark median line, with brown veins, margin broadly brownish cinnamon; fringe white. Expanse of wings: 60 mm. Peru (Rio Huacamaya).

L. abdjesa Schs. Anterior body drab, tegulae intermixed with white, thorax more brown; abdomen *abdjesa*. blackish-brown above, with lighter segmental lines, intermixed with white basally and dorsally, the two last segments white mixed with brown. Forewing white, strewn with chestnut-brown, the lines composed of blackish-brown and orange scales, the anterior one meeting the indistinct median shadow at the inner margin; the posterior line is vertical, slightly incurved between 3 and 2; subterminal line white, irregular; marginal line red-brown, projecting on the veins. Hindwing brown, fringe white. Expanse of wings: 60 mm. Bolivia (Incachaca).

L. gunthierna Schs. Forewing white and brownish cinnamon; abdomen nut-brown above, with light drab *gunthierna*. hair, the last segment white and cinnamon-brown. Forewing white, strewn with brown and black; a very fine, feeble parallel line before the antemedian line which is strewn with blackish-brown and orange; cross-vein streak with a fine black line; the posterior transverse line is coloured like the anterior one, followed by a chiefly orange parallel line; subterminal line purely white, irregular, the fine dark brown marginal line enters into the fringe above and below the ends of the veins. Hindwing dark brownish, fringe white. Expanse of wings: 65 mm. Bolivia (Songo). It is near *favilla*, but it has broader wings and different genital organs.

L. favilla Dogn. (153 g) is greyer, more densely strewn with blackish, the broad brownish-grey transverse *favilla*. lines single, a whitish brightening behind the distal line, and the undulate line is also whitish. Hindwing greyish-brown. Ecuador, Colombia.

L. friburga sp. n. (153 h) is somewhat similar to *favilla*. The whitish ground of the forewing is very *friburga*. densely and coarsely strewn with black and dark brown, scantily with orange; antemedian line double, oblique, of almost the same course as in *dentilinea*, but deep black, distally scaled orange; a large white reniform macula at the cell-end; postmedian line very thick and deep black, almost rectangularly produced between 3 and 4, the postmedian area behind it strewn darker, excepting a purely white line, and projecting with 2 darker pointed notches between 2 and 4 towards the whitish subterminal line; marginal line black, coherent, projecting on the veins, with thick black spots between them on the fringe. Hindwing black. Thorax black intermixed with long white hair. Abdomen black above, orange beneath. From a ♀ from Novo Friburgo in the Coll. NIEPELT.

L. dentilinea Schs. (153 h). Forewing grey with 2 darker red-brown, strongly notched transverse lines, *dentilinea*. the anterior one only dentate at the costal margin, the cell-end streak likewise red-brown. Hindwing blackish-grey, lighter at the distal margin. Abdomen blackish-grey, with deep yellow bands beneath, and yellow lateral tufts. Brazil (São Paulo). Expanse of wings: 66 mm.

L. smithi Drc. Forewing greyish-white densely strewn with red-brown, only the broad red-brown *smithi*. anterior transverse line is visible. Hindwing likewise greyish-white. Abdomen yellowish-white above, all white beneath. Expanse of wings: 62 mm. Colombia.

L. schausi Dogn. (153 g). Forewing white, densely strewn with black and yellow, with 2 black trans- *schausi*. verse lines, the posterior one almost straight, distally accompanied by a black shadow, with a purer white filling between, black crescents at the margin, a black dot behind each of them. Hindwing brownish with traces of a lighter median line; abdomen also brownish. This species described from Venezuela is between *aglone* and *favilla*.

L. obliquilinea Schs. Forewing white strewn with brown, most intensely in the basal area which is *obliqui-* bordered by the double brown antemedian line; a black dot below the base of the cell, and a dark inner- *linea*. marginal shadow; the interior part of the double postmedian line only extends to behind the centre of the cell; undulate line white, shaded darker inside. Fringe white with brown spots. Hindwing blackish-grey, broadly brown at the inner margin, with darker veins and white fringe. Abdomen yellowish-brown above, white beneath. Expanse of wings: 50 mm. British Guiana.

L. irrorata Schs. is allied to *schausi*; forewing white, scantily strewn with brown and yellow; between *irrorata*. the double strongly dentate transverse lines, which are more densely strewn with brown and especially yellow, there is an almost straight median line, slightly dentate only on the veins, distally followed by broad white colour; an irregular brown marginal line in the purer white marginal area. Hindwing white with a dark median line. The ♀ is more densely strewn with brown. Abdomen blackish-brown, with lighter brown segments and a white dorsal line, white beneath. Expanse of wings: ♂ 69, ♀ 90 mm. Costa Rica.

turnina. **L. turnina** Schs. Anterior body cinnamon-brown, intermixed with white, abdomen rusty brown with darker bands. Forewings brown, more cinnamon-brown in the basal area; subbasal line and antemedian line double, interrupted by the veins, mottled darker brown, more prominent owing to intermixed white scales. Median area more intensely strewn with white, a cinnamon-brown spot bordered with white is at the cross-vein; the double dentate postmedian line is cinnamon-brown, the two transverse lines connected by a black submedian streak; a dark brown subterminal shadow with black vein-streaks, a light brown spot at the apex. Hindwing brown, olive-grey at the base. Expanse of wings: 39 mm. French Guiana.

minor. **L. minor** Schs. (153 h). Forewing greyish-white, strewn with brown, most densely so in the basal area which is oblique-triangularly cut off, from the first third of the costal margin to the centre of the inner margin, bordered by a dark undulate line; lightest is the median area before the irregular oblique postmedian line which is almost united with the anterior line at the inner margin; submarginal area and distal margin dark grey, the veins in this part white. Hindwing smoky grey. Abdomen golden brown above, white beneath. The ♀ is lighter. French Guiana.

fassli. **L. fassli** Dogn. is very different and is distinguished by longer palpi and the costal vein of the hindwing arising without a cross-bar to the cell from its centre. Forewing white with broad red-brown markings, a broad median band forming an acute angle at the cell, the basal part of the same colour, bordered by a black line parallel to the median band, margin broad blackish. Hindwing sooty brown, abdomen blackish-brown, with ochreous ringlets, black beneath. Expanse of wings: 52 mm. Bolivia.

suprema. **L. suprema** Schs. (153 h) differs from the other species in the absence of transverse lines. Forewing of ♂ white, with dark red-brown veins, especially the subcosta, median vein and submedian vein; costal margin fine black. The base of the white hindwing is somewhat orange-haired. Forewing of ♀ reddish-brown, the distal part strewn with grey between the veins, hindwing dull brown with white fringe. Abdomen in both sexes black, with orange bands beneath. — Larva yellow, probably green in life, with red transverse bands above the joints, and red subdorsal lines beginning from the 5th segment, red beneath, head black. Food-plant not mentioned.

104. Genus: **Oiozona** Drt.

Only one very peculiar species with a Geometrid-like habitus, yet only to be ranged under the *Noto-dontidae*. The slender palpus with a slightly drooping terminal joint is correct, prolonged in the ♀. Antennae lamellate, in the ♂ with short double pectinations. The abdomen projects beyond the hindwing. Forewing broad with a sharp apex and slightly undulated margin. Neuration similar to that of *Lobeza*, but with an areole on the forewing on which vein 5 arises a little above the centre of the cross-vein, and 6 from below the upper cell-angle, 7—9 stalked. Hindwing very characteristic by the entire fusion of 8 with 7 for two thirds of the length of the anterior edge of the cell after forming a large basal sling.

geometrica. **O. geometrica** Drt. (154 b). Head and thorax bone-white, collar rusty yellow, abdomen and base of tegulae blackish. Forewing sepia-brown with white veins in the median and marginal areas, with 3 whitish transverse bands strewn with brown, the two anterior ones often strangulated spot-like, marginal area of a purer bone-white colour. Hindwing whitish, the ♀ smoky towards the margin. Peru.

105. Genus: **Lusura** Wkr.

Distinguished from the preceding genus by much longer palpi, longer-pectinated antennae, and veins 3 and 4 of the hindwing arising more separated. A few insignificant species.

Type of genus: *L. discalis* Wkr.

discalis. * **L. discalis** Wkr. has blackish-grey forewings strewn with brown, the darker, only curved, not dentate transverse lines hardly noticable in the dark ground; the exterior cell-end shaped like a quadrangular spot is filled with light reddish-brown, its distal border being formed by a straight fine black cell-end streak; instead of the undulate line there is a slight brightening behind which there is one fine black longitudinal streak subapically and at the anal angle. Hindwing white with a grey marginal band. Brazil.

altrix. **L. altrix** Stoll (= *chera* Stoll, *megalops* Sepp, *simois* Wkr.) (154 a) is not dissimilar to *discalis*; forewing somewhat lighter brownish, darkened blackish only before the antemedian line and behind the distally broadly lighter postmedian line in the shape of broad shadowy bands, transverse lines slightly notched, the distal cell-end not lighter; a fine black streak at the cell-end, and a submarginal row of fine blackish internerval streaks, a thicker subapical longitudinal streak. Hindwing whitish. Guiana, Colombia.

L. ancha Schs. is a larger species with broad wings, of a different exterior. Forewing brownish-black *ancha*, with fine indistinct transverse lines, the posterior one composed of small triangular black spots distally edged with whitish-grey; another fine transverse line in the middle, followed by a distinct black line extending to below the cell, bordered with white outside below the cell and connected with a crescentiform streak before the cell-end by a dark streak; 2 black dots at the cell-end itself, 4 small whitish spots behind them; a black undulate submarginal line. Hindwing of the same colouring. Expanse of wings: 40 mm. Paraguay.

L. plorabilis Schs. Forewing steel-black strewn with grey, brownish in the cell and at the base of *plorabilis*, the inner margin, the transverse lines broken up into small dark velvety brown spots, brown shading behind the distal line with 2 rows of small dull brown spots; centre of costal margin strewn with white; a dark brown spot at the cell-end, dark brown lunar streaks at the dusted brownish distal margin, distally edged with reddish-yellow. Hindwing smoky brown. Expanse of wings: 45 mm. French Guiana.

L. falsimonia Dogn. Forewing coal-black, lighter brownish ochreous at the inner margin, below the *falsimonia*, cell and at the margin, still lighter in the cell-end and from there widened to the costal margin; transverse lines broken up into thick black internodal dots as in *plorabilis*, and also a submarginal row of black dots. Hindwing blackish, fringe light. Expanse of wings: 36 mm. French Guiana.

106. Genus: **Nesebra** Schs.

Antennae of both sexes shortly pectinated as far as beyond the middle; palpi slightly drooping with a very short terminal joint. Forewing rather long and narrow, veins 2—4 at equal distances from each other, vein 5 arises from the centre of the cross-vein, 6 from the upper cell-angle, hindwing as in *Scevesia*, but vein 6 on a short stalk with 7, 8 from the centre of the cell.

Type of genus: *N. norema* Schs.

N. norema Schs. Forewing brown, with a velvety brown oblique streak below the base of the cell with *norema*, a white spot behind it, lighter brown in the disc, bordered by a curved brown double line with a black line behind it; behind the uniformly bent postmedian line follows at first a whitish shadow, then a brown one; marginal area grey mixed with lilac, with a subterminal row of small brown spots. Hindwing brown. The ♀ is larger, greyer, with indistinct transverse markings and a postcellular row of small blackish spots. Expanse of wings: ♂ 35, ♀ 46 mm. French Guiana.

107. Genus: **Gluphisia** Bsdv.

This genus being also represented in the palaearctic region (cf. Vol. II, p. 295) occurs in North America in a series of forms which are combined in but two species now. The ♂ antennae are pectinated to the tips, those of the ♀ plain; palpi short, hairy. They are small, insignificantly coloured species with rather narrow forewings; vein 5 arises from the centre of the cross-vein, 6 from the upper cell-angle; hindwing with the usual neuration, vein 8 arises only near the cell-end.

Type of genus: *G. crenata* Esp. from Europe.

G. septentrionis Wkr. (= *septentrionalis* auct., *clandestina* Wkr., *trilineata* Pack.) (154 a) is the smallest *septentrionis*, and most insignificant species; forewing ash-grey, very variably lighter or darker, with more or less distinct transverse lines edged with whitish, and a dark shadowy band behind the anterior line, the median area generally yellowish strewn with black; the submarginal line is twice obtusely broken. Hindwing lighter or darker ash-grey. — f. **ridenda** Edw. (154 a) is lighter grey, the broad median band of a clear light reddish-yellow *ridenda*, colour. — f. **rupta** Edw. is still somewhat lighter whitish-grey with a narrower yellow median band the black *rupta*, border-lines of which cut each other at the inner margin, a darker shadowy band following behind the distal transverse line, absent in *ridenda*. Both forms from Colorado and Montana. — f. **albofascia** Edw. Forewing *albofascia*, more yellowish-grey with a broad dark subbasal shadowy band; median area yellowish-grey with a broad black shadowy band behind it. Hindwing with a faded broad dark band in the marginal quarter. From Utah. — f. **formosa** Edw. is a lighter grey form, chiefly from Texas, with almost white hindwings; the median band *formosa*, of the forewing is quite light flesh-coloured or yellowish, parted by a darker median line which is thickened on the veins; interior transverse line very strong and deep black. — f. **wrightii** Edw. is very intensely strewn *wrightii*, with black, the light median band very dark, light reddish-yellow only above the inner margin in a quadrangular spot, parted by a black median line; postmedian area densely shaded with black as far as the dentate submarginal line. Hindwing dingy white with a darker submarginal shadow. California. — f. **quinquelinea** *quinquelinea*, Dyar, from the Pacific Coast, is a more insignificant form with 5 distinct transverse lines on its grey ground. — Larva green with yellow subdorsal lines and red double dorsal spots except on the 4th and 5th segments. It lives on aspen-trees.

lintneri. **G. lintneri** Grt. (154 a) is a somewhat larger species for which even a special genus, *Eumelia* Neum. & Dyar, was established. Forewing ash-grey or mouse-coloured, with black transverse lines, the anterior one straight, not curved, and with an indistinct cross-vein streak; median area and a small basal spot loamy yellow, small yellow black-scaled submarginal spots. Hindwing just as dark as forewing with a distinct post-
avimacula. median line and a lighter shadow behind it. — f. **avimacula** Huds. has also an ash-grey median area, only intermixed with some yellow scales at the border-lines, containing a dark median area, and a very distinct yellow reniform macula surrounded by black is at the cell-end, the basal spot below the cell is also yellow
slossoni. surrounded by black. — f. **slossoni** Pack. is lighter ash-grey, the basal fifth blackish-brown, the two yellow
severa. spots of *avimacula* are whitish-grey here. — f. **severa** Edw. is a large strong form with a broad blackened median band and the yellow spots of *avimacula*. Hindwing with a blackish median band with a lighter filling;
danbyi. this form flies in California — f. **danbyi** Neum. is a large, very light yellowish loam-coloured form with a scarcely visible lighter median area and feeble transverse lines; the reniform macula is also very fine and
normalis. indistinct. California. — f. **normalis** Dyar is smaller than the preceding forms, the median area yellowish, a very narrow grey tinge on the averted sides of the transverse lines; reniform macula very distinct, filled with grey. — The larva is diaphanous light green with a yellow lateral line and lives on *Populus tremuloides* and *balsamifera*.

108. Genus: **Nagidusa** Wkr.

Antennae of ♂ pectinated to the tips, of ♀ plain; a small tuft on the head. Forewing long and narrow with an oblique margin and a rather pointed apex; as in all the neighbouring genera it lacks the areole, vein 5 arises above the centre of the cross-vein, 6 is stalked with 7--9. Hindwing as in *Gluphisia*. Few tropical American species.

Type of genus: *N. xylocampoides* Wkr.

xylocampoides. **N. xylocampoides** Wkr. (= *exyra* Drc.) (154 a) is a large species with light brown forewings strewn with grey, with a large quadrangular grey costal-marginal spot and a few small dark brown costal spots near the apex. Hindwing white, yellow at the inner margin with a brown marginal line. Venezuela.

cinescens. **N. cinescens** Schs. (= *miranda* Dyar). Forewing grey with fine undulate double black mostly indistinct transverse lines and a dark cell-end streak; an indistinct subterminal shadow, with black vein-streaks and internerval streaks towards the costal margin; fringe speckled dark. Hindwing smoky grey with a whitish postmedian line. Expanse of wings: 47 mm. Mexico, Arizona.

suavis. **N. suavis** Dyar (154 a) is smaller and more slender than the preceding species, forewing violet bluish-grey, strewn with yellowish ochre and red-brown at the costal margin, with red-brown double transverse lines filled with yellowish-ochre, the cell-end macula of the same colouring. Hindwing whitish, fringe greyish-brown, with brown apical lines. Mexico.

mycomba. **N. mycomba** Dyar is also similar, greyish-blue, abdomen black; forewing strewn with black, with double indistinct transverse lines, the posterior one shaded dark behind the cell and above the inner margin; the undulate line is composed of large faded spots between the fine black veins of the marginal area. Hindwing brownish-grey with a light median line at the costal margin and inner margin. Expanse of wings: 42 mm. Mexico (State of Hidalgo).

109. Genus: **Ellida** Grt.

Like the preceding genus, but the origin of vein 5 of forewing is removed down to the centre of the cross-vein, and veins 3 and 4 of the hindwing arise from the same base, not separately. Only one North-American species:

Type of genus: *E. caniplaga* Wkr.

caniplaga. **E. caniplaga** Wkr. (= *transversata* Wkr., *gelida* Grt.) (154 b) is monotonously ash-grey with a contrastingly brown head and collar, the forewing with 3 distinct antemedian transverse lines, the outermost of which extends close to the brown discal spot; 2 indistinct postmedian lines are marked by vein-dots, a submarginal row of small irregular brown spots. Hindwing dark ash-grey. Larva unknown. Canada, New York, Maine.

110. Genus: **Fentonia** Btlr.

Separated from *Ellida* only by the antennae being pectinated not quite to the tips, and by somewhat longer porrect palpi. Forewing somewhat broader, no difference in the neurulation. The genus, also known as *Macrurocampa* Dyar, contains beside a number of Eastern Asiatic species also 3 American species, two of which occur in North America.

Type of genus: *F. marthesia* Cr.

F. marthesia Cr. (= *tesella* Pack., *turbida* Wkr., *elongata* Grt. & Rob.) (154 b) has exactly the exterior *marthesia* of a *Heterocampa*, but no areole on the forewing; greyish-white with a dark blackish-grey basal third distally bordered by a notched double line; postmedian line double, irregularly dentate, followed by a light undulate line behind it, bordered inside by a darker shadow which is only distinct in the upper half of the wing and forms large blackish spots above the anal angle. Hindwing whitish-grey, darkened in the ♀, the postmedian line distally light. The abdomen bears 6 dark dorsal tufts. Forewing occasionally with a somewhat greenish tint. Larva, resembling a larva of *Cerura* by its two long caudal points, grey with a yellow red-spotted dorsal stripe and yellow oblique lateral streaks on 3 segments each; the first segment exhibits a short red cone. It lives on oaks and beeches, and on being molested it sputters forth a fine jet of a liquid, like the larvae of *Cerura* do. Maine to Georgia and Texas; it is said to occur also in Mexico, Guiana, and Brazil.

F. dorothea Dyar on the whole shows the same scheme of markings as *marthesia*, but the basal area *dorothea* is not separated by a darker colour, but also the distal half is brownish-grey like the basal area; the double black transverse lines are distinctly and somewhat more regularly dentate than in *marthesia*; the light notched undulate line is shaded dark inside in its whole length, with 2 thick black small spots above the anal angle; a black double streak at the cell-end represents a narrow reniform macula; hindwing darker greyish-brown, lighter towards the base. California.

F. amazonica Btlr. (154 b) may correspond with the Brazilian specimens identified as *marthesia*; basal *amazonica* third of forewing chocolate-brown, traversed by 3 undulate jet-black transverse lines, distally bordered by the double notched black antemedian line; the distal half of the wing is whitish, finely strewn with reddish-brown, a fine black streak at the cell-end; the postmedian line extends similarly as in *marthesia*, but it is somewhat more oblique, the two double lines more separated, more regularly dentate; the light whitish undulate line is more deeply notched. Hindwing whitish, brownish at the margin. Amazons.

111. Genus: **Notela** Schs.

Like the preceding genera and also without an areole on the forewing, separated by a high frontal tuft. Vein 6 of forewing arises from the upper cell-angle, separated from the stalk of the veins 7—10. Vein 3 of hindwing arises from the same base with vein 4, 6 on a short stalk with 7. Only 2 closely allied species.

Type of genus: *N. jaliscana* Schs.

N. jaliscana Schs. (154 b). Forewing grey strewn with black, especially the veins are blackened, with *jaliscana* brownish shading between the veins and at the indistinct transverse lines, only the posterior one being occasionally distinct and double, dentate; a black dot generally in the lower cell-angle, an oblique row of black streaks below the apex. — **f. ramosa** nov. (154 b) I denominate a common form with a black submedian ray which *ramosa* begins at the base of the inner margin and extends obliquely upwards to the first third of vein 2, below which it is continued to the second third, ending obliquely upwards on vein 4 at the margin, a black anal spot below it. Hindwing whitish. Mexico.

* **N. angustiora** B. & McD. has longer narrow forewings of the same ash-grey colour strewn darker, *angustiora* the double transverse lines more or less broken up into dots, especially the posterior line which is followed by a reddish-brown shadow; a black double streak in the cell, followed by a whitish brightening, an indistinct reniform macula at the cell-end, and black dots before the margin. Hindwing light smoky grey. Arizona.

112. Genus: **Euharpyia** Schs.

Separated from the preceding genus by the antennae being pectinated only in the basal halves, with a long porrect hair-tuft at the base of the antenna; the middle joint of the porrect palpus is longer than in the preceding species. Neuration as in *Notela*. Only 1 species.

Type of genus: *E. comita* Schs.

E. comita Schs. (154 b). Forewing brown in the basal and distal thirds, more grey in the median area, *comita* the anterior double transverse line removed far to the centre, the posterior double line filled with whitish, with vein-dots; small black dots above the anal angle and towards the costal margin before and behind the reddish-brown undulate line. Hindwing light brown, darker distally. Peru, Bolivia.

113. Genus: **Eunotela** Schs.

Like *Euharpyia*, but the palpi are erect, and the hair-tuft at the base of the antenna is absent. Vein 3 of hindwing arises separated from 4.

Type of genus: *E. pallida* Schs.

pallida. **E. pallida** Schs. (154 c) is very similar to *E. comita* on the whole, but of a much lighter colouring; marking also the same except the black subterminal spots which are absent here, and the undulate line is a fine black line with some brownish shading before it towards the apex. Hindwing white, a few black scales at the anal angle. Brazil (Castro, Parana).

tropica. **E. tropica** Schs. is very similar, but at once discernible by its brown hindwings. Forewing light grey, shaded with light brown basally, the double postmedian line very indistinct and interrupted, instead of the absent black subterminal line there are short black vein-streaks before the marginal line; the velvety black crescent at the cell-end is very distinct. Expanse of wings: 40 mm. Venezuela.

collaris. **E. collaris** Schs. Thorax grey with a contrastingly velvety brown head and collar. Forewing brown mixed with reddish-yellow basally, in the cell and in the marginal area, the whitish basal ray strewn with black, a white discal spot bordered with black above, with brown beneath, with a whitish area before it; the double brown anterior transverse line begins with a large brown costal-marginal spot; veins partly strewn with black and white, the postmedian vein is composed of white vein-dots; black dots bordered with grey are between the veins of the marginal area. Hindwing greyish-brown, lighter towards the base. Expanse of wings: 39 mm. Colombia.

bipunctata. **E. bipunctata** Jones. Forewing yellowish-white, dusted with brownish basally, with a yellowish-brown costal-marginal spot behind the postmedian line, a black basal ray and a double anterior transverse line, the interior part of which is faded brown, the exterior part black; 4 dots in the cell, a dark streak at the end; the posterior transverse line is composed of a threefold row of vein-dots; undulate line brown, with one black anal spot each before and behind it, one black spot each before it on the middle radial vein and at the apex; fringe white with small black spots. Hindwing yellowish, veins and margin brownish. Expanse of wings: 34 mm. Corcovado (Rio de Janeiro).

basitincta. **E. basitincta** Dogn. is near *bipunctata*; forewing white strewn with brown, yellowish ochreous basally, with a red-brown border-line; the dentate brown postmedian line is dotted on the veins, followed by a less distinct interrupted line and a red-brown costal spot; reniform macula and undulate line likewise red-brown. Hindwing white, brownish at the margin. Expanse of wings: 32 mm. Amazons.

chacoa. **E. chacoa** Schs. Anterior body reddish-brown, tegulae whitish olive grey, abdomen greyish-brown. Basal area of forewing loamy grey, median area grey, brownish behind it, a brown antemedian shadow bordered by a fine blackish-brown double line, a brown line bordered with white is at the cell-end; the fine postmedian line is bordered with whitish, dark vein-streaks behind it, then a brown shadow meeting an angle of the postmedian line on vein 4; whitish and reddish scales before the fine submarginal line in the lower half. Hindwing white with a fine brown marginal line. Expanse of wings: 27 mm. Argentina (Chaco).

114. Genus: **Pontala** Wkr.

This genus contains only two peculiar species of conspicuous wing-contours, the distal margin forming an angle on vein 5, and one strong dent each at the anal angle and in the centre of the very much indented inner margin. Vein 5 arises from the upper cell-angle, 6 from the apex of the areole. Hindwing as usual.

Type of genus: *P. rubrana* Wkr.

rubrana. **P. rubrana** Wkr. Forewing purple brown with fine red-brown transverse striae bordered with yellowish inside; marking exactly like that of *calpe*, the oblique line from the apex is black, distinctly bordered with light violettish-grey on the outside, faded inside; the second oblique line from the distal-marginal dent is very indistinct, quite absent in some specimens; a thick black subapical dot at the distal margin, another dot above the anal angle. Hindwing whitish, brownish at the distal and inner margins. Brazil.

calpe. **P. calpe** Fldr. (154 c). Forewing deep red-brown with a violet reflection, a fine darker oblique line from the apex to the inner-marginal indentation, another line from the distal-marginal angle to the anal angle. Hindwing dark greyish-brown. Brazil.

115. Genus: **Apela** Wkr.

Separated from the preceding genus only by the rounded distal margin without an angle on vein 5, with broader wings, the basal half of the costal margin rather convex; neurulation the same. A few tropical species have been described.

Type of genus: *A. divisa* Wkr.

A. divisa Wkr. (= *strigata* Mschlr.) (154 c) is a most variable species, if the specimens presumed to *divisa*. belong together are really identical, the inner margin being sometimes very deeply dentate, sometimes quite straight. Forewing copper-red dusted with purple violet, darkened before the purple black oblique line which is bordered somewhat lighter distally, except the broad light costal margin; fringe and inner margin likewise darkened purple blackish, especially at the inner-marginal dent; an oval surrounded by blackish is at the cell-end, a ring-macula in the cell; two distantly separated fine blackish arcuate antemedian lines, the distal one of which ends near the postmedian line at the inner-marginal dent. Hindwing brownish-grey, somewhat lighter towards the base, fringe light. The bright rusty yellow collar contrasts with the purple violet thorax. Colombia.

A. acutidivisa Rothsch. is reddish-cinnamon on the forewing with a yellowish tint, with a deep red- *acutidivisa*. brown oblique band which is faded inside, distinctly defined outside, and extends from the apex into the inner-marginal dent, a very fine antemedian line is very deeply notched. Hindwing brownish pink. Expanse of wings: 38 mm. French Guiana.

A. neobule Drc. (154 c). Forewing yellowish-brown, almost quite yellow along the costal margin, the *neobule*. dark oblique line of *acutidivisa* is double here, a submarginal row of very fine brown dots, and 2 small round spots in the cell; antemedian line very fine. Hindwing reddish-brown, lighter towards the base. Costa Rica.

A. lilacina Dogn. (154 c) resembles *neobule*, but the forewing is dusted with violet, greenish-yellow at *lilacina*. the anterior half of the costal margin and at the anal angle, with a greenish-yellow reniform macula. Hindwing light brownish. French Guiana.

A. picturata Dogn. The inner-marginal dent is prolonged into a small tail twice as long as in the preced- *picturata*. ing species. Forewing red-brown with a yellowish tint, with brownish veins in the postmedian area; a white subbasal double line of an elliptical shape, a large brown cellular spot behind it, and a somewhat smaller rounder one at the cell-end; the brown oblique line is distally set with white vein-dots; 2 dark dots above the anal angle. Hindwing brownish, fringe whitish. Expanse of wings: 35 mm. French Guiana.

A. archimma Schs. ♂ antennae with short ciliary tufts. Anterior body fawn-coloured, intermixed with *archimma*. whitish. Forewing cinnamon-red, suffused with purple, a strong dent at the inner margin; the fine oblique bent subbasal line is partly bordered with white, like the fine excurved antemedian line; the fine white postmedian line is bordered with red-brown inside and extends from the apex behind the inner-marginal dent; ring-macula and reniform macula surrounded by fine dark rings; marginal area slightly strewn with black, a light brown spot at the anal angle. Hindwing fawn-coloured, costal margin lighter. Expanse of wings: 37 mm. Amazons (Rio Ica).

116. Genus: **Dylomia** Fldr.

Structure very similar to that of the preceding genus, but forewing with an obtuse apex and a rounded not indented inner margin; vein 5 arises near the upper cell-angle, 6 from the centre of the areole; the rest of the neuration almost the same; 3 and 4 of hindwing arise either stalked or from the same base. The costal vein branches off from the centre of the cell. Several mostly delicate tropical species have been described.

Type of genus: *D. tortricina* Fldr.

D. tortricina Fldr. (154 d). Forewing deep red-brown with a yellowish-white costal-marginal stripe and *tortricina*. a very large reflecting violet discal spot; the scaled dent at the inner margin is blackish-brown. Hindwing brown with a whitish inner-marginal area. Brazil.

D. ciliata Fldr. (= *consobrina* Schs.) (154 d). Forewing light reddish-yellow with a fine yellowish *ciliata*. ochreous costal margin and a violet spot in the centre of the costal margin; an undulate dark yellow antemedian transverse shadow and a similar dot at the cell-end; a brownish shadow containing white vein-dots is before the red-brown marginal line, a dark violet shadowy stripe scaled lilac is behind it. Hindwing light reddish-yellow, red-brown at the margin. French Guiana, Amazons.

D. ochreata Schs. Forewing ochreous, costal-margin red-brown except the postmedian part remaining *ochreata*. yellow; an irregular darker antemedian shadow, the inner margin before it is shaded lilac; a red-brown dot at the cell-end; a dark yellow submarginal line with white vein-dots is before the dark lilac marginal shadow. Hindwing ochreous, lighter towards the base. Expanse of wings: 29 mm. French Guiana.

D. caesia Fldr. (154 d) is light violettish grey on the head, thorax, and forewing, with a blackish-brown *caesia*. arcuate streak basally below the cell, and a straight postmedian line extending from the darkened brownish-grey apex to the centre of the inner margin, after having formed a right angle on the inner-marginal vein; a very fine parallel line extends before it, 3 blackish small spots behind it before the centre of the margin. Collar, abdomen, and hindwing are bright orange. Brazil.

- delicata.* **D. delicata** Schs. Forewing violet with a brownish ochreous costal margin which is lighter in the distal half, brownish ochreous shading in the centre of the cell; a red-brown antemedian shadow below the cell, the distal half of the inner margin is brownish ochreous; a dark dot in the cell-end, a reddish-yellow subapical streak, a brownish ochreous submarginal shadow below it, fringe reddish-yellow. Hindwing dingy white, dusted with violettish-brown in the distal half. Expanse of wings: 20 mm. French Guiana.
- suavis.* **D. suavis** Jones. Forewing light yellowish-brown, reddish-yellow at the costal margin, shaded somewhat darker in the marginal area; the oblique fine, slightly curved anterior transverse line ends at the inner margin in a long sealed dent, the stronger postmedian line terminates near it in a short sealed dent and comes straightly from the apex; an indistinct subterminal row of small obsolete dark lunular spots, and 2 small spots in the cell-end connected by a dark line; fringe red-brown, prolonged at the inner margin. Hindwing iridescent yellowish. Expanse of wings: 31 mm. Brazil (São Paulo).
- fragilis.* **D. fragilis** Schs. (= nubiloviolaceus *Rothsch.*) (154 d) has light yellow forewings broadly shaded violet and lilac at the costal and distal margins, with a dark brown cell-end dot and a brown notched shadow below the cell-end, distally bordered by a dark brown line, and a white submedian dot; the inner margin behind it is grey and brown, distally bordered by a short white line; a brownish-ochreous shadow bordered with dark brown on both sides is situated before the lower half of the margin. Hindwing dingy white, reddish-brown at the inner and distal margins. Expanse of wings: 30 mm. French Guiana.
- pulverea.* **D. pulverea** Schs. Forewing brown, densely strewn with lilae excepting the distal half of the inner margin and the marginal area; a white oblique line shaded brown inside extends from the apex to the basal third of the inner margin, a white vertical line from vein 2 to the inner margin; one black dot each at the cell-end and subapically, 2 white dots in the upper third of the distal margin; the veins between the cell-end and the oblique line are brown. Hindwing reddish-brown, lighter towards the base. Expanse of wings: 28 mm. French Guiana.
- germana.* **D. germana** Schs. (154 d) is similar, violettish-brown on the forewing, strewn with lilae at the margins; a light oblique line inwardly shaded with brown extends from a black subapical dot to the centre of the inner-marginal vein and bends then distally to the inner margin, towards its angle a similar line extends from the base of the costal margin; a black dot at the cell-end. Hindwing reddish-brown, lighter towards the base. Expanse of wings: 31 mm. French Guiana.
- diversa.* **D. diversa** Dogn. is distinguished by 2 different tints into which the brown oblique line, distally bordered with lilae and extending similarly as in *pulverea*, divides the forewing, the colour above it being reddish flesh-coloured with a lilae tint, below it dark lilae with a reddish flesh-coloured spot; a brown spot in the centre of the costal margin, a small brown dot in the cell, a thick black dot at the apical beginning of the oblique line. Hindwing brownish ochreous, lighter towards the base. Expanse of wings: 26—29 mm. French Guiana.
- transversa-ta.* **D. transversata** Dogn. is allied to the following species; forewing white, strewn with ochre, reddish-yellow at the costal margin, a reddish-ochreous oblique line extends from the apex straight to the first third of the inner margin; a small black dot in the cell-end. Hindwing white, with a slight pink tint at the margin. Expanse of wings: 32 mm. Amazons.
- diagonalis.* **D. diagonalis** Fldr. (154 d). A fine blackish oblique line extends from the apex of the bone-coloured forewing to the first quarter of the inner margin, a small black dot is in the cell-end. Hindwing greyish-white. Amazons.

117. Genus: **Naprepa** Wkr.

The members of this genus number among the largest *Notodontidae* known; they resemble gigantic *Lophopteryx* in colour and scheme of markings. ♂ antennae tuftedly ciliated; the erect palpi have a rather long short-haired middle joint and a very short terminal joint; the mesothorax exhibits a high tuft the end of which is slightly split. Forewing with a dentate distal margin, the inner margin with a sealed dent. Vein 5 arises from the centre of the cross-vein, 6 from the areole near the upper cell-end. Hindwing with the usual neuration, the costal vein proceeds before the cell-end.

Type of genus: *N. camelinoides* Wkr.

camelinoides. **N. camelinoides** Wkr. (154 e) exactly resembles a gigantic *Loph. camelina* and is invariably easily recognizable by the yellow, black-curled abdomen. Brazil (Espírito Santo).

cyllota. **N. cyllota** Drc. (154 e) is quite similar to the preceding species, but the abdomen is light grey, the base and anus reddish-yellow, each segment with a broad black ring. — The larva is very stout on the 3rd and 4th segments, the first segments are light bluish-green, laterally with white, black-ringed spots, the rest of the body bright green with subdorsal white, red-ringed spots and a white undulate lateral line. Food-plant unknown. Mexico, Honduras, Panama.

N. houla Dyar (= *fuscounubilata* Rothsch.) (154 e) is somewhat smaller with broader wings, otherwise *houla*, of the same colouring and marking, though the district of the scaled dent is less scaled white, the same being the case at the anal angle of the hindwing. At once discernible by the unicoloured brown abdomen without black rings. Mexico to Venezuela.

N. flexifera Schs. is most similar to *houla* and apparently only separated by somewhat narrower wings. *flexifera*. Costa Rica.

N. elongata Schs. (154 f.) has the longest and narrowest wings and correspondingly a much longer abdomen. Colouring and marking almost the same as in the preceding species, but the row of light vein-dots behind the postmedian line is absent, and the scaled dent is darker. Brazil (Rio de Janeiro).

N. pulcheria Drc. (154 f.) represents another type; forewing reddish greyish-brown with brown markings, especially a postmedian band crossing a fine whitish zigzag marking at the cell-end. Hindwing reddish-brown, darker at the distal margin with 2 short blackish-brown streaks at the anal angle. Panama.

N. pallescens Schs. is very similar to *pulcheria*, but much lighter, almost yellowish-white, with reddish-brown markings, only the light brown postmedian line extends below the cell as a thick black line into the scaled dent, light lilac dusting extends along the median vein to the margin; a reddish-brown shadow extends from the lower cell-angle obliquely to the margin below the apex. Hindwing much darker brown, whitish only at the costal margin. Expanse of wings: 72 mm. Brazil.

N. adusta Rothsch. (154 f) is a very different species with relatively narrow forewings, light brown, densely darkened violettish-brown excepting the basal half of the costal margin and the cell, with rather indistinct double fine deeply notched transverse lines and fine long dark brown internerval streaks behind the centre in the costal-marginal half. Hindwing lighter brown with the usual black anal spot parted by light. From Peru and Bolivia.

118. Genus: **Lophopteryx** Stph.

This genus which is also represented in the palaearctic regions (cf. Vol. II, p. 306) is very closely allied to the preceding genus, only separated by the differently stalked subcostal branches, the 3 middle ones arising on a joint stalk, whilst 7 and 10 are separated; in *Naprepa*, however, the two lowest are stalked. The palpi are more porrect, the ♂ antennae serrate with ciliary tufts. America harbours only one species very similar to the European *camelina*.

Type of genus: *L. camelina* L.

L. americana Harv. (154 d). I cannot say to what extent this species corresponds specifically to the European species (Vol. II, p. 306), it seems to be rare in America, and the stages of its metamorphosis have apparently not yet been observed there. Both are entirely alike excepting the somewhat more compressed and broader shape of the wings. Pennsylvania, Wisconsin, Kansas.

119. Genus: **Herbertina** Schs.

Very closely allied to the preceding genus, distinguished by less ciliated, not serrate ♂ antennae, as well as a small hair-tuft on the head. The costal vein of the hindwing arises from the centre of the cell, in *Lophopteryx* near the end of the cell. Only 1 species:

Type of genus: *H. eumeta* Drc.

H. eumeta Drc. is distinguished by a dark brown median line on the red-brown forewing, with yellow crescentiform spots on either side of it, one large yellow spot each is at the cell-end and apex, a yellow stripe extends from the base to the anal angle, and a series of small yellowish-white spots before the margin; 2 black dots at the apex, one at the anal angle. Hindwing dark brown with a black anal spot. Expanse of wings: 32 mm. Colombia.

120. Genus: **Azaxia** Dyar.

Likewise extremely similar to the preceding genera, separated by the 3 lowest subcostal branches being stalked, whilst the second from above (10) arises from the long and narrow areole which is much shorter in the neighbouring genera. Only 2 species.

Type of genus: *A. luteilinea* Drc.

luteilinea. **A. luteilinea** Drc. (154 g) has purple brown forewings broadly mixed with yellowish-green, with double dentate grey transverse lines, a large black spot at the cell-end and 3 black apical spots; 2 white dots above the anal angle. Hindwing yellowish-white, with dark brown veins and a black anal spot, fringe yellowish-green. Peru, Bolivia.

dyari. **A. dyari** Schs. (154 g) is very similar to *luteilinea*; forewing dark lilac grey, mixed with green at the costal margin, whitish at the inner margin with green and olive brown markings, apex and anal angle whitish, strewn with green, the transverse lines as in *luteilinea*, with a green and reddish-brown mixture below the cell; a velvety blackish-brown lunar spot at the cell-end; the fine double postmedian line is reddish-brown, small blackish-brown spots are subapical. Hindwing white strewn with blackish-brown, most densely so at the margin, with an indistinct white postmedian line and a dark anal spot. Costa Rica.

121. Genus: **Marcella** Dogn.

Closely allied to *Naprepa* anatomically, but the ♂ antennae are pectinated long, the pectinations ciliated, the palpi much shorter; the costal vein of the hindwing arises only behind the centre of the cell. The subcostal branches of the forewing are as in *Azaxia*. Only 1 species has been described.

Type of genus: *M. volcancita* Dogn.

volcancita. **M. volcancita** Dogn. Forewing reddish yellowish-brown, strewn with red-brown on the two first subcostal thirds, the veins and the inner margin, strewn with green below the median vein and before the apex, the cell blackened, mixed with green at the end; a faded black median line forms an angle postdiscally, a black stripe is at the cell-end; the dentate postmedian line is indistinct, black internodal dots are behind it, 2 postcellular dots are thicker; the ends of the veins are strewn with white. Hindwing yellowish red-brown, darker at the margins, with a blackish-brown anal spot. Expanse of wings: 50 mm. Colombia (Quindiu).

122. Genus: **Odontosia** Hbn.

This genus which is distributed also in the palaearctic regions (cf. Vol. II, p. 305) has the antennae pectinated to the ends, short palpi, rather long forewings with a dentate oblique margin, a strong scale-dent at the inner margin, none of the subcostal branches stalked. Thorax without a tuft. Only 2 American species.

Type of genus: *O. carmelita* Esp. from Europe.

elegans. **O. elegans** Stkr. (154 g). Forewing brown, darkened in the costal-marginal area, without transverse lines, with a silvery white basal ray along the inner-marginal vein. Hindwing light yellowish, with a large brown anal spot below which the inner-margin is yellowish; 2 or 3 black internodal streaks are subapical.

grisea. From Canada to the Rocky Mts. — f. **grisea** Stkr. (= *notaria* Edw.) is a more ash-grey form from Colorado.

viridifusca. **O. viridifusca** Schs. differs from the diagnose of the genus in the almost entire-margined, not dentate margin, otherwise the same. Forewing moss-green, broadly violettish-brown at the inner margin, with similar costal-marginal spots from which the distinct transverse lines proceed, the posterior one with white vein-spots; grey dentate shadows are behind the grey cell and before the postmedian line; black double dots at the margin are centred white above the anal angle; the centre of the distal margin is dusted reddish-brown. Hindwing blackish-brown with a black and white anal spot. Expanse of wings: 35 mm. British Guiana.

123. Genus: **Dottia** Schs.

Separated from *Odontosia* by the ♂ antennae not being pectinated to the tips, and by the doubly split anal tuft; the costal vein of the hindwing arises near the cell-end. Only 2 species.

Type of genus: *effecta* Schs.

effecta. **D. effecta** Schs. (154 g). Forewing red-brown, dusted with violet as far as the fine double dentate postmedian line, with a light green basal ray as far as the double dark brown anterior transverse line at which there is a white dot at the submedian fold; 2 dark stripes extend from the cell-end to the margin; the ♂ exhibits a dark-shaded white spot above the anal angle, another one between the veins 4 and 5. Hindwing blackish-brown. Costa Rica.

boliviata. **D. boliviata** Schs. Anterior body yellowish sand-coloured and brown, abdomen brown. Forewing brown in the basal area above, reddish ochreous below the cell, bordered by 2 dark lines; median area creamy yellowish as far as the lower cell-angle and along the costal margin to the apex; cross-vein black, rusty brown stripes behind it above and below 5, the upper one extending to the margin; 3 indistinct fine brown lines behind the cell; cellular branches deep reddish olive, finely bordered with brown towards the margin, the marginal area being yellowish mixed with olive; inner margin partly dusted with rusty brown. Hindwing smoky brown with a light postmedian shadow. Expanse of wings: 47 mm. Bolivia.

124. Genus: **Ribaldia** Dyar.

Like *Dothia*, but the second and third subcostal branches, counted from below, on the forewing are stalked. Only 1 species.

Type of genus: *R. amatame* Dyar.

R. amatame Dyar. Forewing wood-coloured brown, strewn darker, with a prominently dark brown *amatame*. median area and a small elliptical light discal spot in it; only the posterior one of the transverse lines bordering on the median area is dentate on the veins; a subterminal row of black very indistinct spots. Hindwing whitish, strewn with blackish at the margin, with a dark anal spot and pink fringe. Expanse of wings: 39 mm. Mexico (Hidalgo).²

125. Genus: **Hyperaeschra** Btlr.

This genus occurring in the Indian regions (Vol. X, p. 642) has also half a dozen of North American representatives. ♂ antennae pectinated to the tips, palpi hairy. Distal margin of forewing entire-margined; neuration as in the preceding genera, but all the subcostal branches of the forewing are stalked except the uppermost.

Type of genus: *H. pallida* Btlr. from India.

H. stragula Grt. (= *scitipennis* Wkr.) (154 g) is a pretty easily recognisable species with violettish- *stragula*. grey forewings, reddish-yellow at the inner margin, with a chestnut-red basal spot and undulate line; basal ray deep red-brown, 2 subapical streaks also red-brown; fragments of the transverse lines are lighter grey. Hindwing brownish-grey with a red-brown marginal line. — f. **manitou** Neum. & Dyar has not the reddish- *manitou*. yellow tinge at the inner margin of the forewing, but it is more monotonously violettish-grey, it also lacks the chestnut-red basal spot, only single red-brown scales are at the undulate line. Hindwing lighter brownish-grey. Colorado, California. — f. **pacifica** Behr is a darker form with an almost black thorax, from Cali- *pacifica*. fornia. — f. **ochreata** B. & McD., described from Utah, is lighter ochreous brown with a large bluish-black *ochreata*. spot behind the cell-end with 2 small whitish spots in it; marginal area and basal half of inner margin likewise bluish-black, undulate line less undulate. Hindwing white with a bluish-black anal spot. — The larva is exactly like that of *ziczac*, lilac whitish-grey, marbled brownish, a brown dorsal line extends to the apex of the second protuberance; the last segments are raised and rusty brown mixed with yellow. It lives on willows and poplars. Widely distributed in the United States.

H. georgica H.-Schäff. (154 h). Forewing greyish ochreous with a short silvery white basal ray and *georgica*. white dentate transverse lines bordered with black, the median area between them blackened in the inner-marginal half; 2 black subapical internerval streaks. Hindwing dingy white. — Larva smooth, without protuberances, green, irrorated yellowish-white, strewn with irregular dull red dots which are condensed into two lines; a yellow dorsal stripe bordered with red is very broad on the 5th and the 7th and 8th segments. It lives on oaks in September. Its range extends from Maine to Texas.

H. tortuosa Tepp. differs from *georgica* in the darker brownish-grey forewing without the white *tortuosa*. basal ray, the black transverse lines are scarcely dusted white, much more notched and irregular; the median area is scarcely darkened in the proximal half, but a broad faded red-brown median line is nearer to the postmedian line; a black streak at the cell-end, and 2 subapical strong black internerval streaks. Hindwing whitish brownish at the margin. Colorado.

H. tropicalis Schs. (154 h). Forewing brown with whitish hair, the darker brown transverse lines — *tropicalis*. a median line is double — are partly accompanied by small whitish spots; a dark longitudinal line extends through the cell, a few darker spots at the end, and a black line is at the cell-end with white scales behind it; the veins of the marginal area are blackened. Hindwing brown, reddish-yellow basally. Expanse of wings: 40 mm. French Guiana.

126. Genus: **Astapa** Dogn.

Two thirds of the ♂ antennae are provided with short ciliated pectinations; palpi rather long, hairy, with a short terminal joint. Forewing relatively broad with a rounded distal margin, with a long pencil-shaped hair-scale dent; neuration stated to be the same as in *Ribaldia*. Only 1 species.

Type of genus: *A. signata* Dogn.

A. signata Dogn. Forewing rusty yellowish brown, dusted with green at the costal margin, in the *signata*. cell-end, behind it and submedianly, blackish in the basal half of the cell, the veins strewn with black and white, marked very much like *M. volcancita*, with a black angular median line and an almost parallel postmedian line composed of lighter internerval rings, a black cell-end streak and a double row of black subterminal dots. Hindwings blackish, fringe light, with a black and white anal spot. The species varies in the intensity of the marking, and in the colour which may even turn violettish-pink. Expanse of wings: 31—37 mm. Colombia.

127. Genus: **Libyssa** Dogn.

Very similar to the preceding genus from which it differs in the tuftedly ciliated antennae and shorter palpi. Veins 3 and 4 of the hindwing arise from the same basis, separately in *Astapa*. Only 1 species.

Type of genus: *L. viridirosea* Dogn.

viridirosea. **L. viridirosea** Dogn. is a smaller species with light pink forewings, brownish at the base and the 2 first thirds of the inner margin, light green submedianly, behind the cell and subapically, as well as on the fringe; a submarginal double row of black dots, the interior row being thicker, between the veins. Hindwing blackish with a pink tinge, and a brown and white anal spot. Expanse of wings: 28 mm. French Guiana.

128. Genus: **Notodonta** Ochs.

This widely distributed genus (cf. Vol. II, p. 299) has also two representatives in North America. Antennae of ♂ shortly pectinated, of ♀ plain. Distinguished by the absence of the areole on the forewing, 7—10 being forked together with 6 and arising from the end of the cell. The costal vein of the hindwing arises near the cell-end. No larvae known.

Type of genus: *N. dromedarius* L.

basitriens. **N. basitriens** Wkr. (154 h) is coloured and marked like the European *trepida*; forewing ash-grey strewn with reddish-brown, with a large rusty brown basal spot, bordered by a double notched red-brown line, the dentate postmedian line is bordered with whitish outside and is continued on the light, distally smoky hindwing. Atlantic States.

simplaria. **N. simplaria** Graef (154 h). Forewing ash-grey, blackish basally, with 2 dark dentate transverse lines bordered with a lighter colour on the averted sides, the cell-end streak surrounded with whitish; a submarginal row of small dark internerval spots. Hindwing whitish. From the Northern Atlantic States.

129. Genus: **Lophodonta** Pack.

Structured exactly like *Notodonta*, but both sexes with plain antennae. Two North-American species.

Type of genus; *L. ferruginea* Pack.

ferruginea. **L. ferruginea** Pack. (154 h). Forewing red-brown at the base and in the median area, the rest very dark ash-grey, whitish in the anterior upper half of the median area with blackish scales, two rusty red notched transverse lines bordered with whitish on the averted sides, and a whitish undulate line. Hindwing dingy white, narrowly smoky at the margin, with a grey postdiscal band. Canada to Colorado. — The stout larva is green with double yellowish-white dorsal lines, some small yellow lateral spots and a short red below yellow lateral line from the head to the first two segments. It lives on *Betula*, especially *B. papyrifera*.

angulosa. **L. angulosa** Abb. & Sm. is marked like *ferruginea*, only the postmedian line is less undulate, but the colouring is much lighter ash-grey, and the median area is of the same colour, not red-brown, only the transverse lines are red-brown, whitish on the averted sides, bordered with white on both sides at the costal margin. Hindwing as in *ferruginea*. — The larva is more slender than that of *ferruginea*, green with a double white dorsal line, with 3 lateral yellow dots on each segment, and a yellow lateral stripe bordered with red-brown above; it lives on oak and pupates in the soil. Massachusetts to Georgia and Florida.

130. Genus: **Pheosia** Hbn.

Likewise very closely allied to the preceding genera and separated by pectinated antennae in both sexes. Only the 4 lowest subcostal branches of the forewing are stalked, vein 6 arises from the cell-end. (Cf. also Vol. II, p. 297).

Type of genus: *P. tremula* Clerk from Europe.

rimosa. **P. rimosa** Pack. (= *californica* Stretch) (154 h) is the exact image of the European *tremula*, only the forewing is apparently a bit broader on an average, and the brownish marginal shadow somewhat broader and darker. — The larva occurs also in the same two colourings, green or brown, but it differs constantly in a long pointed Sphingid horn on the penultimate segment. It lives on poplars and willows. Distributed from British Columbia to Maine and New York. The name *dimidiata* H.-Schäff. which was formerly given to the species refers to a tropical insect: *Rhuda dimidiata* (cf. p. 986) and is due to a mistake.

P. portlandia *Edw.* (= *descherei* *Neum.*) which was formerly regarded as a melanotic form of *rimosa portlandia*, is considered to be a distinct species now. Shape and marking the same, but the disc of the forewing is not white but mouse-coloured, the brown parts are almost black. Hindwing dingy white with a broad smoky grey marginal band and a large dark anal spot. Somewhat larger on an average. Alaska to California.

131. Genus: **Calomathetes** *Dyar.*

Shape and exterior very similar to that of the palaearctic genus *Pterostoma*; ♂ antennae pectinated long to the tips. Distal margin of forewing dentate, a broad scale-dent in the middle of the inner margin and one before the anal angle; the uppermost and lowest subcostal branches are free, the 3 middle ones stalked. The obliquely rising palpi are densely scaled below, but not so long as in *Pterostoma*. Only 1 species.

Type of genus: *C. halmaphylla* *Dyar.*

C. halmaphylla *Dyar* (155 a). Forewing whitish strewn with brownish, somewhat more yellowish *halmaphylla* in the cell and behind it, dusted with violettish-grey in the basal and marginal areas, with fine double dentate transverse lines, with black and white vein-dots behind the exterior line; discal fold finely striped black, double in the basal half of the cell, 3 black dots at the cell-end; instead of the undulate line there are small purple blackish spots bordered with white inwardly; veins of marginal area striped black. Hindwing brownish, fringe lighter. Mexico.

132. Genus: **Goacampa** *Schs.*

The long antennae are shortly pectinated in the ♂, serrate in the ♀, the very short palpi are porrect. Forewing long and narrow, with a long areole; vein 6 arises before the centre of it, the 4 lowest subcostal branches from the end of the areole. Vein 5 of the hindwing is absent here and in all the following genera, and 6 arises on a rather long stalk with 7, and 8 close from the cell-end. Only 1 extremely variable species.

Type of genus: *G. variabilis* *Schs.*

G. variabilis *Schs.* (155 a). The nomenclatural type has whitish-grey forewings with a silky gloss, with *variabilis* a darkened blackish basal area, notched single black transverse lines, the posterior one of which fades away more or less towards the costal margin, with a large reniform macula surrounded by black; the subterminal line represented by black internerval wedges behind which the ground is somewhat lighter whitish, besides some shorter wedges before the margin; fringe speckled white on the ends of the veins. Hindwing white, darkened black before the snow-white fringe, with a broader wedged area before the anal angle. This form has an expanse of 43—46 mm and was described from Oaxaca in Mexico, but it occurs also in Colima. — Another form of only half its size (expanse of wings: 35 mm) has a much darker forewing coarsely strewn with black, without the silky gloss, with less distinct markings, I denominate: **tehuacana** *f. nov.* (155 a), from *tehuacana* Tehuacan in the State of Puebla; the hindwings are neither purely white here, but smoky brownish. — *f. diminuta* *f. n.* (155 a) is a still much smaller form with a wing-span of 25 mm, so that there is no resemblance whatever between this dwarf and the type. Forewing uniformly grey, the marking almost extinct. Hindwing whiter than in *tehuacana*. This is the western coast form from Guerrero. Nevertheless all three are most probably one species, for all of them exhibit the same aberration, since the submedian fold may be sometimes darkened black from the base to the margin: — *ab. nov. striata* (155 a); the space behind the cell may occasion- *striata* ally also be black as far as the margin as in the figured specimen; the reniform macula of other specimens is entirely filled with black, but it is of no use denominating all these forms which may also be combined.

133. Genus: **Pilodonta** *Dogn.*

This genus contains but one species so far; it is allied to the preceding genus and differs in a longer and stronger middle joint of the palpus, a much longer abdomen and peculiar long and fine hair of the cell on the forewing and of the costal margin on the hindwing. Veins 3 and 4 of hindwing on a short stalk.

Type of genus: *P. subcrinita* *Dogn.*

P. subcrinita *Dogn.* has quite monotonously ash-grey forewings strewn slightly darker, with whitish *subcrinita* strewing at the base and along the costal margin; only a small dot encircled by white is at the cell-end. Hindwing somewhat lighter. Expanse of wings: 57 mm. French Guiana.

134. Genus: **Ursia** B. & McD.

Likewise only one very different small species from North America. Antennae bipectinate not quite to the tips, palpi diminutive. The narrow forewing with a straight costa has almost the neuration of *Goacampa*, but vein 6 arises almost from the apex of the areole, veins 3 and 4 of the hindwing arise separately and the costal vein arises nearer at the centre of the cell.

Type of genus: *U. noctuiformis* B. & McD.

noctuiformis. **U. noctuiformis** B. & McD. (155 a). Forewing grey, striated darker and dusted whitish; a white streak extends from behind the lower cell-end almost vertically to the inner margin which is continued towards the apex as a dark oblique shadow with some black longitudinal streaks in it before the margin; the area behind the white line and the shadow is lighter than the inner part, with small indistinct white internerval spots; fringe speckled. Hindwing brownish-grey. Arizona.

135. Genus: **Kurtia** Schs.

Antennae of ♂ with long pectinations as far as the apical fifth, palpi hairy, the long and narrow forewing with a convex inner margin and a very oblique distal margin; vein 5 is removed upwards to the upper cell-angle, 6 arises behind the middle of the very long areole. Neuration of hindwing as in *Goacampa* except the costal vein which arises in the middle of the cell. Only 1 species.

Type of genus: *K. modesta* Schs.

modesta. **K. modesta** Schs. (155 b). Forewing dark red-brown with indistinct grey internerval streaks, and traces of transverse lines at the costal margin; a series of tiny dark spots behind the centre and small black internerval spots before the margin. Hindwing dull brown. Venezuela.

136. Genus: **Anita** Schs.

Antennae of ♂ pectinated except the apical fifth, palpi rising with a very short terminal joint. Forewing short and broad with the same neuration as the preceding genus, but the costal vein arises near the base of the cell. A small number of tropical species:

Type of genus: *A. basipuncta* Schs.

basipuncta. **A. basipuncta** Schs. (= *costalis* Schs., *albonubila* Dogn.) (155 b). Forewing light brown, whitish above the median vein, with a velvety brown basal spot, the veins of the marginal area striped dark brown; a fine dot in the upper cell-angle and shadowy traces of a postmedian line. Hindwing light brownish. Venezuela.

gigas. **A. gigas** Roths. is the largest species, near *basipuncta*, with slate-coloured forewings strewn with white at the base and costal margin, the transverse lines scarcely visible in the ground-colour, and with a black notched subterminal line. Hindwing brownish-grey. Amazons (Fonte Boa).

norella. **A. norella** Schs. Forewing brown, grey in the basal area at the costal margin, mixed with reddish-yellow below it, with fine black antemedian and postmedian transverse lines, a stronger median line, of a velvety black colour; a large brown spot in the cell, white vein-dots and a brown shadow behind the postmedian line, then follows a whitish-grey transverse area enclosing large black spots; a grey shadow between the base of the median nervules. Hindwing dark brown. Expanse of wings: 37 mm. French Guiana.

syрта. **A. syрта** Schs. Forewing brown with a broad white base of the costal margin and dentate blackish transverse lines which are red-brown towards the inner margin, a thick black cellular spot and a red-brown cell-end streak; white vein-dots and black streaks are behind the postmedian line; submarginal black spots surrounded by whitish, a brown marginal line behind them. Hindwing dark brown. Expanse of wings: 34 mm. French Guiana.

minima. **A. minima** sp. n. (155 b) is the smallest species; forewing brown, base of the costal margin broadly white, the white apical third of the costal margin of the shape of a triangle the apex of which extends down to vein 2; a broad dark brown band from the first third of the costal margin obliquely to the lower cell-angle meets here a similar one in almost a right angle, which extends from the centre of the costal margin to the anal angle before which, however, it disappears; a thick black spot in the base of the cell. Transverse lines double, notched, black, with black and white vein-streaks behind the posterior line; thick black spots subterminally in the white area, those between 5 and 7 being situate farther towards the margin; small black vein-spots between 4 and 8 behind a fine whitish submarginal line. Hindwing brown, lighter basally. Described according to 1 ♂ from Thomar (Coll. Stgr. in the Berlin Museum).

galibensis. **A. galibensis** Schs. (= *basiplaga* Roths.). Forewing dark velvety brown in the basal third, light grey behind it above the median vein; brown below it, with 2 very deeply notched postmedian transverse lines;

a small velvety brown spot in the cell, a ring-shaped macula at the end; another submarginal black dentate line. Hindwing dark brown. Expanse of wings: 44–50 mm. French and British Guiana.

A. essequiba Schs. (155 b). Forewing broadly light yellowish-brown at the base, distally bordered by *essequiba*. one brown spot each at the costal and inner margins; light brown behind it, whitish in the upper half of the median area, traversed by a dark brown lunular line bordering on the basal area below the cell; at the cell-end there is a narrow spot filled with grey and white, a deeply notched blackish-brown line behind it, followed by the brown postmedian line, which is distally bordered with white, with long black vein-streaks behind it; marginal third strewn white in the upper half, with 2 black dentate lines in it. Hindwing dark greyish-brown. British Guiana.

A. definitiva Dogn. (155 b). Basal half of forewing blackish-brown, strewn with lilac, separated from *definita*. the light red-brown, white-irrorated distal area by 2 black parallel lunular lines, with a white and red-brown reniform macula and a double short line filled with light lilac behind them; the black postmedian line is strong and irregularly dentate, black subterminal lunae are bordered with white, the two uppermost form spots with 2 tiny costal spots before them; the margin is of a pinkish tinge with a dark line in it. Hindwing white, grey at the costal and inner margins, narrowly grey at the distal margin. Expanse of wings: 42 mm. Amazons (Taperinha).

A. albipalpis sp. n. (155 c) is very similar to *definita*; interior half of forewing light reddish violettish *albipalpis*. grey, light brownish cinnamon in the distal half, somewhat lilac subterminally, of a pink tinge before the margin; some indistinct, slightly darker and feebly dentate antemedian transverse lines, shortly before the centre there is a fine black transverse line bordered with reddish on both sides; behind it follows, as a boundary between the grey and reddish tints of the wing, a whitish somewhat notched transverse band which contains the white reniform macula centred with red-brown at the cell-end and recedes a little in the submedian area; the fine black postmedian line somewhat lighter reddish on both sides, before and behind it there are yet very indistinct violettish-grey transverse lines parallel to it, white dots behind it on the veins; subterminal slate-coloured spots are between the veins which are strewn with black and white, a large white spot is before the two anal spots; behind the fine irregular submarginal line the veins exhibit white dots, black ones on the ends of the veins; fringe whitish, finely spotted red-brown above and below each end of the veins. Hindwing light reddish-brown, lighter discally. Described according to a ♀ from Brazil. Palpi white laterally. Type in the Mus. Senckenberg.

A. lassa Schs. (= *squalida* Dogn.) which was recently placed to *Kurtia* has light brown forewings, *lassa*. shaded dark steel-grey in the basal third below the cell and from the centre of the cell to the costal margin, moreover subapically at the costal margin and at the inner angle, with 3 small velvety black antemedian spots below each other, a postmedian double row of black vein-dots with internerval streaks behind them, and oblong grey marginal spots bordered with black. Hindwing dark brown. Expanse of wings: 50 mm. French Guiana.

A. divisa Schs. (155 c) is deep blackish-brown in the smaller basal half, traversed by numerous velvety *divisa*. black undulate lines and defined towards the reddish cinnamon distal area by a notched velvety black antemedian line; inner margin and subterminal area shaded with violettish-grey, before and behind the regularly dentate postmedian line there are yet several undulate-dentate parallel lines of a somewhat darker colour than the ground; a whitish reniform macula filled with violettish-grey is at the cell-end, the ground behind and before it being shaded with violettish-grey; a subterminal row of small slate-coloured spots. Hindwing white, narrowly brownish at the margin. Colombia.

137. Genus: **Postanita** Dyar.

Separated from *Anita* by the costal vein of the hindwing arising only at the cell-end; the only smaller species of the genus is otherwise very similar to *Litodonta*, but it has a very feeble, almost absent vein 5 of the hindwing; besides the ♀ has plain antennae, and the hindwings are not hairy beneath.

Type of genus: *P. decurrens* Dyar.

P. decurrens Dyar. Forewing yellowish-brown, shaded dark purple brown behind the base, obliquely *decurrens*. to the costal margin and along the inner margin only strewn to the distal margin; a blackish-brown dot at the cell-end, a grey stripe from the cell to the margin, and a spot above it. Hindwing whitish-brown, grey at the costal and distal margins, spotted brown at the anal angle. The ♀ is strewn darker with traces of dark transverse lines, the anterior one of which borders on the violettish-brown area, and with a very large blackish-brown discal spot. Hindwing chocolate-brown. Mexico.

138. Genus: **Navarcostes** Schs.

This genus has much longer and narrower wings than the preceding genera, moreover the antennae of both sexes are pectinated beyond the middle, and above the thick palpi with a short terminal joint there is one hair-tuft on each side of the frons; the legs also exhibit thin hair-tufts, the abdomen projects far beyond the hindwing. Neuration similar to that of the preceding genera. Only 1 species.

Type of genus: *N. limnatis* Schs.

limnatis. **N. limnatis** Schs. (= *medulla* Dogn.) (155 c). Forewing grey strewn with brown, a whitish submedian spot near the base and a reddish-yellow apical spot; one black dot each in the centre and at the end of the cell; 3 brown antemedian transverse lines and two postmedian ones, a few small black spots at the inner margin; behind the postmedian lines follow small brown internerval spots and then an interrupted black subterminal line, small brown spots behind the latter. Hindwing greyish-brown. Colombia, Guiana.

139. Genus: **Pamcoloma** Schs.

Separated from the preceding genera by tuftedly ciliated, not pectinated antennae, hairy palpi and legs, the wings beneath being very hairy. Neuration slightly different, veins 6 and 7 of the hindwing arise from the same basis without a stalk and the costal vein arises before the centre of the cell. Two species have been described.

Type of genus: *P. marita* Schs.

marita. **P. marita** Schs. has light grey forewings strewn with brown, darkened at the margins, with double dark brown dentate transverse lines; a dark spot in the cell, one dark spot each behind the postmedian line near the costal margin and inner margin, a yellowish-white blotch before the costal margin; oblique dark marginal streaks before the grey, black-speckled fringe. Hindwing dark violettish-brown, somewhat lighter basally. French Guiana. Expanse of wings: 37 mm.

mus. **P. mus** Mschlr. (*refervens* Schs.) is allied to *marita* and differs in the margins of the wings not being darkened, a threefold antemedian line, double cell-end streaks instead of the absent cellular spot, a double median line at the costal and inner margins, and a complete subterminal row of black spots. Hindwing dark brown. The ♀ has a darkened median area and white dusting behind the postmedian line. French and Dutch Guiana. Expanse of wings: ♂ 37, ♀ 39 mm.

140. Genus: **Kaseria** Schs.

Separated from *Pamcoloma* by the antennae being pectinated in the basal two thirds and the costal vein arising only behind the centre of the cell. Only 1 species.

Type of genus: *K. pallida* Schs.

pallida. **K. pallida** Schs. (= *gemonia* Schs.) (155 c). Forewing silvery white scantily strewn with light brown and with fine brown transverse lines, the posterior one partly double, with a large spot, strewn with red-brown, before it in the costal half; small brownish submarginal spots. Hindwing light brown, scantily scaled. Guiana to Brazil.

141. Genus: **Brecontia** Dyar.

Extremely similar to the two preceding genera, distinguished by the separate origins of veins 3 and 4 on the hindwing, the costal vein arising from the centre of the cell; the areole is very long and narrow. The ♀ antennae are pectinated in the basal halves. Only 1 species was described hitherto.

Type of genus: *B. plagipennis* Dyar.

plagipennis. **B. plagipennis** Dyar. Forewing whitish clay-coloured with a large chocolate-brown spot from the base of the costal margin to the postmedian line, reaching in the middle to the inner-marginal vein and forming outside two rounded projections below and behind the cell, and besides this spot is traversed before the centre by a light notched transverse line; a large round black spot at the cell-end; in the subterminal centre follows a distally trilobate brown spot into which a marginal spot penetrates which ends narrowed towards the costal and inner margins. Hindwing brown, lighter basally. Peru, described according to a single ♀.

142. Genus: **Ginaldia** Schs.

Likewise very similar to the preceding genera, separated by tuftedly ciliated antennae. Forewing with an oblique distal margin, the origin of vein 5 removed up to the upper cell-angle, 6 arises from the centre of the areole. Only 1 species.

Type of genus: *G. davidsoni* Schs.

davidsoni. **G. davidsoni** Schs. (= *diminuta* Dogn.). Forewing white, scantily strewn with black and brown, with double transverse lines, the anterior one very oblique, the posterior one broken up into vein-dots, with a black

basal ray and a large black cell-end spot; a brown submarginal shadow and double vein-dots are before the upper half of the margin. Hindwing white with a brown marginal line. French Guiana. Expanse of wings: 35 mm.

143. Genus: **Bahaia** Dyar.

From this genus to the end the species mostly lack the areole of the forewing and at the same time vein 5 of the hindwing. Antennae of ♂ not pectinated to the tips, a hair-tuft is on the vertex; vein 6 of forewing on a joint stalk with the 4 lower subcostal branches, 5 arises from the centre of the cross-vein. The costal vein on the hindwing branches off from the centre of the cell. Only 1 species.

Type of genus: *B. sceletaria* Dyar.

B. sceletaria Dyar (155 c). Forewing light grey, strewn with violettish-brown scales, and with a red-brown longitudinal patch through the cell, then darkened by brown shading obliquely as far as below the apex, bordered below by an undulate brown line, forming an angular spot below vein 2; traces of interrupted lines are visible. Hindwing whitish. The ♀ is more monotonous and less marked, with darker hindwings. Mexico (Colima).

144. Genus: **Procolax** Schs.

The exterior is exactly like that of the following genus *Colax* from which it differs in the subcostal branches being differently stalked, vein 10 proceeding from the joint stalk farther towards the apex than vein 7; besides the ♀ has tuftedly ciliated antennae.

Type of genus: *P. apulana* Schs.

P. apulana Schs. (155 d). Shaped and marked exactly like the following species, but the forewing is of a lighter red-brown colour, the inner margin and distal area lighter brownish-grey, the costal margin strewn with iron-grey; the black transverse lines are more distinctly prominent on the light ground-colour. Costa Rica to Brazil.

145. Genus: **Colax** Hbn.

Antennae of both sexes pectinated in the basal two thirds, the short palpi hairy, hair-tufts at the bases of the antennae. Distal margin of the narrow forewing angular on vein 5, concave below it; vein 6 of forewing stalked with the 4 lower subcostal branches, the second subcostal branch from above arises proximally from the lowest. Veins 3 and 4 of hindwing arise separately, the costal-marginal vein branches off from the centre of the cell.

Type of genus: *C. apulus* Cr.

C. apulus Cr. (155 d). Forewing purple blackish mixed with chestnut-red, especially basally and in the cell, lighter greyish-brown at the inner margin and distal margin behind the whitish, notchless subterminal line, with black angular transverse lines, and 2 small silvery white spots obliquely above each other at the cell-end. Hindwing diaphanous light grey, darkened at the apex. Guiana to Colombia.

C. phocus Schs. (155 d) is extremely similar to *apulus*, but the forewing is much darker velvety brown, the inner margin and distal margin are somewhat lighter, the postmedian line is not so very undulate and the two silvery spots in the cell are near together. Hindwing white, brownish-grey only at the inner margin and the fringe. Brazil (Rio de Janeiro).

146. Genus: **Schausiades** Dogn.

Exterior exactly like that of a *Hemiceras lepidoides* from which genus, however, it differs in the second subcostal branch from above arising separately from the cell, vein 5 arises from the upper cell-angle. Neuration of hindwing not essentially different, the ♂ exhibits a triangular stigma at the anal angle, exactly as in *Hemiceras*. Antennae of ♂ pectinated on half their length, palpi rather long. Only two species.

Type of genus: *S. lepidoides* Dogn.

S. lepidoides Dogn. Forewing brownish olive with a more yellowish oblique band from the first quarter of the costal margin towards the anal angle, another band in the distal half of the costal margin, a darker broad oblique shadow between them; transverse lines broken up into vein-dots, the posterior one extending almost into the apex. Hindwing blackish with lighter fringe and a stigma of almost the same colour. Peru. Expanse of wings: 46 mm.

almothes.

S. almothes Schs. is closely allied to *lepidoides*; thorax and forewing white, strewn with light brown; anterior transverse line fine, undulately excurved, with single blackish-brown scales, an indistinct light brown oblique shadow at the cross-vein; the undulate-dentate postmedian line arises from a chestnut-brown spot at the costal margin and extends to the centre of the inner margin, the marginal area behind it is light brown between 6 and the inner margin. Hindwing and stigma cinnamon-brown. Expanse of wings: 18 mm. Brazil (Rio Purus).

147. Genus: **Hemiceras** Guen.

This genus comprises a huge number of very homogeneous species which are often extremely similar and difficult to separate, and were formerly assigned to the "*Noctuae*". Half or a little more of the ♂ antennae are pectinated, those of the ♀ plain or studded with ciliary tufts, or also pectinated. The smoothly scaled palpi with a long middle joint and a short terminal joint project a little beyond the frons. Vein 5 of forewing arises near the upper cell-angle, 6 from the centre of the long areole from the end of which the 4 lower subcostal branches arise from a joint stalk. Hindwing without vein 5, vein 6 stalked with the subcostal vein. The ♂ hindwing of a great many species exhibits a triangular area of modified scent-scales near the anal angle. The inner margin of the forewing is variably shaped, either straight or cut out, often with a long dent in the centre, often also with another dent at the anal angle. The larvae, as far as they are known, bear a wart-like protuberance on the 11th segment; judging from the figure by CRAMER, the larva of *meona* has another one on the 4th or 5th segment.

According to a recent statement by CARLOS C. HOFFMANN *), the larvae of several species of *Hemiceras* — especially *H. subochraceum* Wkr., *transducta* Wkr., *muscosa* Schs., and smaller numbers of *alba* Fldr., *micans* Schs., and *cotto* Dyar — have done great harm to Mexican coffee-plantations in a rather peculiar way, i. e. by stripping the trees of leaves, which are absolutely necessary for the growth of the young coffee-plants. These trees belong to the family of Leguminosae, especially a species of Inga, called "Chalú" in the district of Chiapas. As the *Hemiceras* develop as many as 3 generations a year, the trees having shot forth for the second time naturally decay on their being stripped once more, so that the young coffee-trees cannot develop. Unfortunately no descriptions of the larvae are given, which would have been very desirable; it is only stated that the larvae are brown or green. The vast numbers of *Hemiceras* occurring there may be concluded from the great number of imagines captured on lamps, forming more than 30 percent of the total number, which means very much considering the enormous swarms of Moths flying to these lamps.

In 1908, H. G. DYAR (Proc. Ent. Soc. Wash. IX, p. 56) supplied a very serviceable table determining the species known at that time. As it is almost hopeless to find one's way through the multitude of species solely by means of descriptions and figures, we have made use of this table as a basis on the following pages, and have added more than 60 species that have been newly described in the meantime. In this way we hope to have facilitated the determination of this extremely complicated and difficult group.

Type of genus: *H. pallidula* Guen.

Key of Determination.

I. Transverse lines of forewing not dentate, at least the exterior one.

A. Three transverse lines: a subbasal, interior and exterior one.

1. Interior line marked by a white cellular spot *gortynoides*.

2. No white cellular spot present.

a. Forewing clouded light and dark *plusiata*.
b. Forewing unicoloured.

a¹ Ground-colour from a light brown to grey.

b¹ Undulate line marked whitish, dentate.

c¹ Forewing with 1 discal dot *variegata*.

c² Forewing with 2 discal dots *jejuna*.

b² Undulate line not or feebly marked blackish.

c¹ Forewing dark *beata*.

c² Forewing light.

d¹ Hindwing white *cadoca*.

d² Hindwing not white.

*) An. Inst. Biol. Mexico, II, 2, p. 151, 1931.

- e¹ Exterior line straight, parallel to the margin.
 - f¹ Forewing brownish.
 - g¹ Hindwing blackish brown *indistans*.
 - g² Hindwing light brownish cinnamon *turijafa*.
 - f² Forewing ash-grey *echo*.
- e² Exterior line oblique
 - f¹ Proceeding near the apex *proximata*.
 - f² Proceeding far from the apex *liboria*.

a² Ground-colour dark red-brown.

- b¹ Subbasal and interior lines straight.
 - c¹ Exterior line shaded light grey outside *satelles*.
 - c² Exterior line not shaded *plana*.
- b² Subbasal and interior lines slightly undulated *striolata*.

B. Only two transverse lines, an interior and exterior one, the subbasal one obliterated.

1. Exterior line straight.

a. Exterior line ending at apex or close before it.

a¹ Interior line straight.

- b¹ Thorax beneath black *affinis*.
- c¹ 1 or 2 spots or dots at the cell-end.
 - d¹ 2 discal dots obliquely above each other, or if the upper one be obliterated, only a small one in the lower cell-angle.
 - e¹ Collar contrastingly dark.
 - f¹ Forewing dark, lines distinct, three-coloured.
 - g¹ Only 1 discal dot.
 - h¹ Hindwing white, brownish only on the veins and margin . . . *flavorufa*.
 - h² Hindwing light brown with a dark marginal band . . . *chromona*.
 - g² Two discal dots *tricolora*.
 - f² Forewing yellowish.
 - g¹ Forewing brownish yellow, lines distinct *maronita*.
 - g² Forewing straw-coloured, lines indistinct *ochrospila*.
 - e² Thorax and collar of the same colour.
 - f¹ Hindwing without a stigma.
 - g¹ Lines with white vein-dots *piccolata*.
 - g² Lines without white vein-dots.
 - h¹ Vertex white *saron*.
 - h² Vertex not white *linea*.
 - f² Hindwing with a stigma.
 - g¹ Costal margin of forewing of the same colour.
 - h¹ Forewing purple, hindwing whitish *cayennensis*.
 - h² Forewing bronze-brown, hindwing brown.
 - i¹ Interior line distinct.
 - k¹ Lines without white dots *bilinea*.
 - k² Lines with white dots.
 - l¹ Stigma of hindwing dark *calaonis*.
 - l² Stigma of hindwing of the same colour *consobrina*.
 - i² Interior line indistinct *stupida*.
 - g² Costal margin of forewing white.
 - h¹ Hindwing whitish, stigma brown *kearfotti*.
 - h² Hindwing brown, stigma brown *daguana*.
- d² Discal dot a large spot.
 - e¹ Collar contrastingly dark brown, stigma of hindwing present.
 - f¹ Forewing straw-coloured, discal spot large *lissa*.
 - f² Forewing grey, strewn with brown.
 - g¹ Hindwing not white.
 - h¹ Discal spot blackish, hindwing brown.
 - i¹ Hindwing dark brown *unimacula*.
 - i² Hindwing light brown *ursara*.
 - h² Discal spot obliterated, hindwing yellowish *leucospila*.

- g² Hindwing white *pohli*.
 - e² Collar and thorax of the same colour.
 - f¹ Forewing dark brown *astigma*.
 - f² Forewing light.
 - g¹ Forewing with a silky shine, costal margin orange *sericilinea*.
 - g¹ Forewing not shiny, costal margin of the same colour . . *buckleyi*.
 - c² An oblique streak at the cell-end.
 - d¹ Stigma of hindwing present.
 - e¹ Forewing dusty grey *vecina*.
 - e² Forewing brown.
 - f¹ Hindwing brown *colombia*.
 - f² Hindwing yellowish-white *cadmioides*.
 - d² Stigma of hindwing absent.
 - e¹ Forewing yellowish, veins broadly striped *striata*.
 - e² Forewing brownish, veins finely striped.
 - f¹ Inner margin with a dent *cadmia*.
 - f² Inner margin without a dent *congrua*.
 - a² Interior line curved.
 - b¹ Vertex greyish-white, forewing unicoloured.
 - c¹ Forewing brownish ochreous, hindwing white *aroensis*.
 - c² Forewing brown.
 - d¹ Forewing dark bronze-brown.
 - e¹ Forelegs of ♂ with thick woolly hair *manora*.
 - e² Forelegs of ♂ smoothly scaled *laurentina*.
 - d² Forewing reddish-brown, dusted with lilac.
 - e¹ Inner margin dentate, lines with vein-dots *ceiba*.
 - e² Inner margin not dentate, lines without vein-dots *cinnoma*.
 - b² Vertex purple, costal margin of forewing bronze-yellow *flava*.
 - b. Exterior line ending far before the apex.
 - a¹ Only one transverse line.
 - b¹ Costal margin of forewing reddish-yellow *semililacea*.
 - b² Costal margin of forewing pinkish cinnamon *teffea*.
 - a² Two transverse lines.
 - b¹ Lines parallel, subterminal line distinct, straight *ruizi*.
 - b¹ Lines divergent, subterminal line indistinct.
 - c¹ Discal dot separated, oblique.
 - d¹ Hindwing dark brown, stigma not contrasting.
 - e¹ Undulate line present, shaded inside *indigna*.
 - e² Undulate line absent *subdigna*.
 - d² Hindwing light.
 - e¹ Hindwing white *buscki*.
 - e² Hindwing brownish.
 - f¹ Hindwing whitish-brown, stigma contrasting *corema*.
 - f² Hindwing reddish-brown, stigma not contrasting *daguensis*.
 - c² Discal dots united forming a spot.
 - d¹ Discal spot indistinct.
 - e¹ Exterior line straight, light.
 - f¹ Lines with black vein-dots *domingonis*.
 - f² Without black vein-dots *refuga*.
 - e² Exterior line curved.
 - f¹ Lines light, bordered with dark *moresca*.
 - f² Lines dark *triopas*.
 - d² Discal spot large, black.
 - e¹ Costal margin not white *clarki*.
 - e² Costal margin white *siderea*.
 - 2. Exterior line curved in the lower half.
 - a. Exterior line not angular subcostally.
 - a¹ Exterior line ending far before the apex.
 - b¹ Two obliquely arranged discal dots.

- c¹ Light straw-coloured *serana*.
 c² Brown.
 d¹ Lines light, bordered with dark.
 e¹ A large species, costal margin shaded dark brown.
 f¹ Forewing darkred-brown, stigma of hindwing scarcely conspicuous *modesta*.
 f² Forewing light reddish-brown, stigma of hindwing contrasting *liboria*.
 c² A smaller species, costal margin not shaded.
 f¹ Inner margin slightly dentate.
 g¹ Hindwing brownish with a darker margin *transducta*.
 g² Hindwing white with a brownish margin *climaca*.
 f² Inner margin strongly dentate *dentata*.
 d² Lines with dark vein-dots.
 e¹ Chestnut-brown *nigrigutta*.
 e² Brownish ochraceous.
 f¹ Hindwing without a stigma, vein-dots distinct *castanea*.
 f² Hindwing with a stigma, vein-dots indistinct *castaneoides*.
 b² No two discal dots.
 c¹ Marked as dots.
 d¹ Three dots in a triangle.
 e¹ The three dots very strong *trinubila*.
 e² The three dots very feeble *joinvillea*.
 d² The three dots united by a line *postica*.
 c² An indistinct spot at the cell-end *barina*.
 a² Exterior line ending at the apex or close before it.
 b¹ Wings long and narrow, bronze-yellow *longipennis*.
 b² Wings broad.
 c¹ Forewing yellowish-white *albulana*.
 c² Forewing not yellowish-white.
 d¹ Forewing dull brown *avangareza*.
 d² Forewing chestnut-brown, median area violet *olivencia*.
 b. Exterior line angled subcostally.
 a¹ Forewing dark brown, interior line angular *crassa*.
 a² Forewing not dark brown, interior line undulate.
 b¹ Exterior line straight, with white vein-dots.
 c¹ Margin of forewing not dentate. *anguilinea*.
 c² Margin of forewing undulate-dentate *taperinha*.
 b² Exterior line curved, without white dots.
 c¹ Postmedian line of forewing without spots at the inner margin *commentica*.
 c² Postmedian line of forewing with dark spots at the inner margin *reyburni*.
 b³ Exterior line scalariformly interrupted *scalata*.
 b⁴ Exterior line bent up to the cell and the submedian line *jovita*.

II. Transverse lines of forewing dentate.

A. Exterior line angular subcostally.

1. A large species, forewing truncate, with an ellipse at the cell-end *truncata*.
 2. A smaller species, wings normally shaped.
 a¹ Forewing greyish olive *undilinea*.
 a² Forewing reddish-brown *trapezina*.

B. Exterior line not angular or indistinct.

1. Forewing contrastingly two-coloured.

a. Forewing metallic yellowish-olive and purple grey.

- a¹ Costal margin contrastingly light.
 b¹ Head white *metallescent*.
 b² Head and collar white *vinicosta*.
 a² Costal margin of the same colour as the wing.
 b¹ Basal area contrastingly light yellowish.
 c¹ Median area purple grey *meona*.
 c² Median area coppery brown *splendens*.

- b² Basal area not contrasting.
 - c¹ Forewing triangular, disc of hindwing white *sabis*.
 - c² Forewing normal, disc of hindwing brown.
 - d¹ Anterior line not undulate, but angular.
 - e¹ Antennae of ♀ plain, interior line slightly angular *deornata*.
 - e² Antennae of ♀ peetinate, interior line very angular *zula*.
 - d² Anterior line undulate *losa*.
 - b. Forewing yellowish and brownish-violet.
 - a¹ Costal margin broadly light yellow *pallidula*.
 - a² Costal margin of the same colour.
 - b¹ Forewing grey with a yellowish cellular spot *ovalis*.
 - b² Forewing without a distinct cellular spot.
 - e¹ Forewing with a bronze gloss.
 - d¹ Forewing red-brown with a pink tinge *egregia*.
 - d² Forewing red-brown with a greenish olive tinge.
 - e¹ Hindwing without a stigma *aena*.
 - e² Hindwing with a stigma.
 - f¹ Forewing greenish olive *oleagina*.
 - f² Forewing more brown *stigmata*.
 - e¹ Forewing without a bronze gloss.
 - d¹ Hindwing with a stigma.
 - e¹ Exterior line dentate, forewing with yellowish spots *nebulosa*.
 - e² Exterior line dotted dentate, forewing not spotted *nubilata*.
 - d² Hindwing without a stigma.
 - e¹ Exterior line dotted dentate.
 - f¹ Forewing dark yellow, linear dots small *flavescens*.
 - f² Forewing dark brown, dots large.
 - g¹ Wings narrower, hindwing whitish *punctata*.
 - g² Wings very broad, hindwing dark brown *lavior*.
 - e¹ Exterior line straight, dotted *celia*.
 - e. Forewing dark purple brown strewn with lilae white or greenish spots.
 - a¹ Hindwing with a stigma.
 - b¹ Forewing metallie violettish-brown.
 - e¹ Hindwing white, stigma black *carmelita*.
 - e² Hindwing yellowish, stigma brown *nupera*.
 - b² Forewing dark brown with greenish-white spots *constellata*.
 - a² Hindwing without a stigma.
 - b¹ Costal margin of forewing white.
 - e¹ Forewing greyish-brown *sparsipennis*.
 - e² Forewing purple brown *coatina*.
 - b² Costal margin of forewing not white.
 - e¹ Hindwing brownish-white, anal angle of forewing dentate *muscosa*.
 - e² Hindwing dark brown, anal angle not dentate *evanescens*.
- 2. Forewing not contrasting, unicoloured.
 - a. Forewing with a bronze gloss, costal margin purple, hindwing white *poulsoni*.
 - b. Costal margin of forewing equally coloured.
 - a¹ Hindwing without a stigma.
 - b¹ Forewing without a dent at the anal angle.
 - c¹ Inner margin curved, cut out basally.
 - d¹ Hindwing light brown *brunnea*.
 - d² Hindwing whitish, veins and margin brownish *arbogasta*.
 - c² Inner margin of forewing straight.
 - d¹ Forewing yellowish-brown *perbrunnea*.
 - d² Forewing deep purple brown *princeps*.
 - b² Forewing dentate at the anal angle *amanda*.
 - a² Hindwing with a stigma.
 - b¹ Costal margin of forewing white.
 - c¹ Forewing reddish-brown.
 - d¹ Hindwing not purely white.

- e¹ Exterior line of forewing punctiform.
 - f¹ Smaller, hindwing with a narrow marginal shadow *conspirata*.
 - f² Larger, hindwing with a broad marginal shadow *gigas*.
- e² Exterior line of forewing forming a white undulate line at the costal margin and inner margin *hidulpha*.
- d² Hindwing purely white *colorata*.
- c² Forewing dark brown, hindwing brown *levana*.
- c³ Forewing light violettish grey, hindwing whitish *cinescens*.
- b² Costal margin of forewing not white.
 - c¹ Exterior line coherent, slightly dentate.
 - d¹ Hindwing brown, stigma large.
 - e¹ Ground-colour monotonous.
 - f¹ Discal spot large, lobate.
 - g¹ Lines black *nigriplaga*.
 - g² Lines red-brown *mutoca*.
 - f² Discal spot not lobate.
 - g¹ Discal spot round *cotto*.
 - g² Discal spot divided into 3 dots *serrata*.
 - d² Hindwing whitish, stigma small *punctilla*.
 - c² Exterior line broken up into dots, dentate.
 - d¹ Discal spot large, oval, black *pagana*.
 - d² Discal spot indistinct.
 - e¹ Forewing greyish-white *alba*.
 - e² Forewing from ochreous to brown.
 - f¹ Median area prominently black *nigrescens*.
 - f² Median area not darkened.
 - g¹ Costal margin of forewing black or iron grey.
 - h¹ Forewing with a dent at the anal angle.
 - i¹ Hindwing brown *nigricosta*.
 - i² Hindwing diaphanous white with brown veins *imitans*.
 - h² Forewing with a rounded anal angle.
 - i¹ Hindwing whitish with dark veins and margin *phocas*.
 - i² Hindwing purely white.
 - k¹ Stigma very narrow, cinnamon-brown *praxides*.
 - k² Stigma larger, dark brown *eustalhia*.
 - g² Costal margin of forewing not black.
 - h¹ Forewing with a dent at the anal angle.
 - i¹ Dark brown, shaded black.
 - k¹ Marginal shadow not united with the cellular spot *singula*.
 - k² Marginal shadow united with the cellular spot.
 - l¹ Hindwing white between the veins *violascens*.
 - l² Hindwing dark blackish-brown *singuloides*.
 - i² Not very dark brown.
 - k¹ Red-brown, basal and marginal areas with a bronze gloss *sericita*.
 - k² Yellowish-brown, basal area of the same colour.
 - l¹ A large species, monotonous.
 - m¹ Without lilac *micans*.
 - m² With lilac *lilacina*.
 - l² Smaller, costal area lighter.
 - m¹ Light, stigma small, reddish-brown.
 - n¹ Exterior line normal.
 - o¹ Inner margin dentate, hindwing white *rufescens*.
 - o² Inner margin sinuous, hindwing glossy reddish-yellow *rufula*.
 - n² Exterior line extraordinarily near to the margin *casiaclara*.
 - m² Dark, stigma large, dark brown.
 - n¹ Interior line continuous, bent *metastigma*.
 - n² Interior line dotted, angular *torva*.

- h² Forewing without a dent at the anal angle.
 - i¹ Hindwing white, stigma contrastingly brown.
 - k¹ Monotonously red-brown, lines indistinct *velva*.
 - k² Mixed with brass-colour, lines distinct *soso*.
 - i² Hindwing shaded brown, stigma brown.
 - k¹ Forewing reddish-brown, without a darker shading.
 - l¹ Postmedian line punctiform *quebra*.
 - l² Postmedian line quite dentate.
 - m¹ Hindwing white with a brown stigma and margin *elphega*.
 - m² Hindwing whitish, veins and margin brownish *monegonda*.
 - k² Dark brown, not reddish.
 - l¹ Lines bordered with reddish-yellow.
 - m¹ Broadly and distinctly bordered *nubilata*.
 - m² Narrowly and indistinctly bordered.
 - n¹ Antemedian line punctiform *pernubila*.
 - n² Antemedian line linear *noctifer*.
 - l² Lines not bordered with reddish-yellow.
 - m¹ Dark, a larger species.
 - n¹ Very monotonous.
 - o¹ The dots connected by a line *turnina*.
 - o² Only dots.
 - p¹ Hindwing whitish *subochraceum*.
 - p² Hindwing brown *vinvala*.
 - n² Transverse lines more distinct, hindwing lighter *lotula*.
 - m² Lighter, a smaller species.
 - n¹ Ground-colour brown.
 - o¹ Brownish-grey, Brazil *tulola*.
 - o² Reddish-brown, Costa Rica *rava*.
 - n² Grey, Argentina *ravula*.

gortynoides. **H. gortynoides** Schs. (155 c). Forewing dark reddish-brown dusted with violet, especially at the straight inner margin, with a white interrupted basal line and a large white cellular spot traversed by an undulate red-brown line, with a small costal-marginal spot above it; a dark spot at the cell-end, a white postmedian spot at the costal margin, a grey line below it to the inner margin. Hindwing whitish with grey hair, dark brown distal margin, veins and stigma. Expanse of wings: 38 mm. French and British Guiana to the Amazons.

plusiata. **H. plusiata** Fldr. (155 e). Forewing lilac-grey with a purple reflection and mixed with red-brown, especially subterminally, with 3 straight transverse lines bordered with a somewhat lighter colour. Hindwing brownish-grey. Colombia, Bolivia.

variegata. **H. variegata** Dogn. is allied to the following *jejuna*; forewing light brown with 3 fine white transverse lines the course of which is somewhat more rounded than in *jejuna*; white dusting in the basal third of the inner margin and at the distal margin, more broadly dusted apically; 2 black dots at the cell-end, the upper one small, it may also be absent. Hindwing rusty brownish with a scarcely darker stigma and whitish fringe. Expanse of wings: 32—34 mm. Amazons.

jejuna. **H. jejuna** Schs. Forewing whitish, densely strewn with light brown, so that only the 3 straight transverse lines remain white, one black vein-dot each at the antemedian line with a grey shadow behind it; a dark grey spot at the cell-end, the inner margin is somewhat sinuate, the veins of the marginal area are strewn with black. Hindwing greyish-brown, whitish basally. Expanse of wings: 38 mm. Trinidad, Amazons. Allied to *indistans*.

beata. **H. beata** Schs. Forewing brown, strewn with lilac, especially at the costal margin, behind the interior transverse line, and at the anal angle; the median one of the white transverse lines is shaded darker brown outside, the two others inside, the two anterior ones are somewhat angular subcostally; a dark spot at the cell-end, and a brown shadow at the margin below the centre. Hindwing brown with a darker stigma. The ♀ is more intensely strewn with lilac. Expanse of wings: 33 mm. Described from French Guiana.

obliquicola. **H. obliquicola** Wkr. (= *cadoca* Schs.) Forewing light reddish ochreous strewn with olive grey, veins darker; transverse lines brown, the basal one from below the base of the cell obliquely to the interior line near the inner margin; only the lower half of a narrow olive grey undulate-linear shadow is present. Hindwing white, brownish at the inner margin and distal margin, with a brown stigma. Expanse of wings: 40 mm. Brazil.

H. indistans *Guen.* (155 e). Forewing pinkish brownish with 3 straight white transverse lines, the *indistans*, middle one distally bordered with dark, the two others bordered inside with dark; an oval darker shadow at the cell-end; the indistinct light undulate line shaded darker inside. Hindwing blackish-brown with a darker stigma and whitish fringe. Brazil.

H. turiafa *Schs.* Anterior body cinnamon brown intermixed with white. Abdomen brownish. Forewing *turiafa*, with a straight inner margin, fawn with a silky gloss and an olive tint, strewn with whitish, with fine brown transverse lines: a subbasal one bordered with light outside forms 2 small lunules; anterior transverse line bordered with whitish inwards, the inner margin behind it as far as the anal angle blackish-brown and clouded lilac grey; cross-vein and cellular veins dark and strewn with white; the straight postmedian line is bordered with white, and dotted somewhat white on the veins; a dark parallel shadow behind it; costal margin finely white. Hindwing and stigma brownish cinnamon, fringe white. Expanse of wings: 31 mm. Brazil, Rio Purus (Hyutanahan).

H. echo *Dyar* (155 e) is marked exactly like *indistans*, but the ground-colour is a very light whitish *echo*, ash-grey, more intensely strewn with brownish-grey between the transverse lines, a lighter area at the anal angle. Hindwing whitish with brown veins, margins, and stigma. Guiana, Peru.

H. proximata *Dogn.* (155 e) is very similar to the two preceding species and differs in the darker *proximata*, red-brown strewing on the white ground with a white costal margin and white transverse lines, the exterior one of which ends much nearer at the apex than in *indistans* and *echo*; the marginal area is somewhat whiter with 2 small dark shadowy spots analwards. The whitish hindwing is brownish, especially at the veins and margin, with a contrastingly brown stigma. Expanse of wings: 40—46 mm. Brazil (Sa. Catharina).

H. satelles *Schs.* Forewing dark olive brown with violet transverse lines, the two anterior ones bordered with reddish-brown inside, a darker streak at the cell-end; a lilac shadow behind the distal transverse line, a darker undulate linear shadow before the margin in the lower third. Hindwing very dark brown, veins and stigma still darker. Expanse of wings: 36 mm. French Guiana.

H. plana *Btlr.* (155 f) is very similar to *satelles*, but the postmedian line is distally not shaded with *plana*, violettish-grey, the colour of the forewing is somewhat more reddish, the hindwing not so dark brown. Brazil, Colombia.

H. striolata *Btlr.* is also very closely allied to the preceding species, the red-brown colour of the *striolata*, forewing is somewhat darker owing to darker strewing, and the two interior transverse lines are not quite straight, but slightly undulate. Brazil.

H. affinis *Drc.* (= *astigma Dyar*) (155 f) is easily discernible from all the similar species by the black *affinis*, underside of the thorax. Forewing reddish-brown with two dark brown transverse lines bordered with light on the averted sides, the exterior line extending from the apex to the centre of the inner margin, the vertical interior one reaching neither the costal margin nor the inner margin. Hindwing white, brownish at the distal margin, without a stigma. Peru.

H. chromona *Schs.* is most similar to the following *flavorufa*. Head and collar cinnamon red, thorax *chromona*, more yellowish, abdomen brownish above, whitish beneath. Forewing reddish-yellow with fine straight lines bordered with light on the averted sides, the anterior one vertical, blackish-brown, the posterior one cinnamon-brown, from the apex to the centre of the inner margin; a small round black, often extinct spot at the cell-end, small dark subterminal dots on 3 and 4. Hindwing and stigma light reddish-yellow, the margin dusted brownish cinnamon. Expanse of wings: 35 mm. Brazil, Rio Purus.

G. flavorufa *Dogn.* (155 f). Forewing light red-brown with a large black discal dot and 2 oblique *flavorufa*, red-bronze lines which are only 3 mm distant from each other at the inner margin, the exterior one into the apex. Hindwing white, veins, distal margin and stigma contrastingly red-brown. Guiana, Peru, Bolivia.

H. tricolora *Dyar* (155 f) is very similar to *flavorufa*, but it has double discal dots; forewing more *tricolora*, brownish pink, finely strewn darker, the transverse lines dark brown on the sides facing each other, red-brown in the middle, and ochreous on the averted sides; 2 dark dots connected by a faint shadow are in the centre of the marginal area. Hindwing whitish, veins, margin, and stigma brownish. Peru.

H. maronita *Schs.* Forewing reddish-yellow, finely strewn with brown, with fine red-brown transverse *maronita*, lines which are dark grey on the sides facing each other, the exterior one from the apex to the centre of the straight inner margin. Hindwing whitish, veins, margins, and stigma light red-brown. Allied to *leucospila*. Expanse of wings: 40 mm. French Guiana.

H. ochrospila *Dyar* (155 f). Forewing lighter straw-coloured, very finely strewn darker, the feeble *ochrospila*, yellowish transverse lines extend as in *maronita*, bordered with brown on the sides facing each other; 2 dots at the cell-end. Hindwing straw-coloured, stigma very light brown. French Guiana.

H. piccolata *Dogn.* Forewing brown, somewhat lighter in the marginal area, the dark, light-edged *piccolata*, transverse lines with white vein-dots on the averted sides, both ending close together at the inner margin; 2 black dots at the cell-end, the veins are black and strewn with white. Hindwing light brown, without the stigma. Allied to *calaonis*, *affinis*. Expanse of wings: 44 mm. Colombia.

- saron*. **H. saron** Dogn. Forewing yellowish-brown, the veins strewn grey and white, with 2 dark transverse lines bordered with light, the exterior one almost parallel to the distal margin; two feeble dark dots at the cell-end. Hindwing white, no stigma, feebly brownish on the veins and margin. Vertex and abdomen white. Peru.
- linea*. **H. linea** Guen. is similar to *saron*, separated by the vertex being coloured like the thorax, not white; ground-colour somewhat darker, exterior transverse line more oblique so that the two lines are nearer together at the inner margin. Brazil, Bolivia (Songo).
- cayennensis*. **H. cayennensis** Schs. (155 g). Forewing lilac brown with darker veins, the vertical interior line dark brown, the oblique exterior one reddish-brown, distally bordered with light; a narrow dark streak at the cell-end, irregular darker shadows before the margin; inner margin slightly sinuate. Hindwing whitish, veins, distal margin, and stigma dark brown. Allied to *bilinea*. Expanse of wings: 43 mm. French Guiana.
- bilinea*. **H. bilinea** Schs. (155 g) is very similar to *cayennensis*, but the forewing is more reddish-brown with a slight bronze gloss, the veins strewn with grey, the two olive grey transverse lines ochreous on the averted sides; inner margin somewhat more dentate. Hindwing brown, stigma inconspicuous. Common in Mexico.
- calaonis*. **H. calaonis** Dyar. Forewing dark red-brown, the interior dark brown transverse line is dotted white on the veins, the exterior one bordered with golden yellow towards the margin; two brown dots obliquely above each other are at the cell-end; yellowish shading instead of the undulate line before the margin. Hindwing light brown, with a very large dark brown stigma, veins and margins brownish. Separated from the similar *stupida* by the distinct interior line. Peru.
- consobrina*. **H. consobrina** Dogn. looks very much like *piccolata*, the inner margin is more sinuate, the two discal dots are confluent, the exterior less oblique line ends farther away from the apex, both are more distantly separated at the inner margin. Hindwing light brown, the stigma contrasts scarcely, as it is of the same colour. Forewing somewhat more greyish-brown. Expanse of wings: 42—45 mm. Peru.
- stupida*. **H. stupida** Schs. Forewing light brown, veins strewn with black and yellowish, costal and inner margins dusted somewhat reddish yellow; anterior transverse line very fine, the exterior one much thicker, dark brown, extending from the apex to the centre of the inner margin; a fine dark brown streak at the cell-end, subterminal grey shadows parallel to the postmedian line. Hindwing scantily scaled, whitish, dusted brown in the distal half, with a dark brown stigma. Expanse of wings: 35 mm. Dutch Guiana (Paramaribo).
- kearfotti*. **H. kearfotti** Dyar differs from *stupida* in the fine white costal margin of the forewing; forewing brown with a pink tinge, strewn somewhat darker especially on the veins, the lines as in *calaonis*, the interior one likewise with white vein-dots. Hindwing as in *stupida*. Brazil.
- daguana*. **H. daguana** sp. n. (157 a) looks like *kearfotti*, but it is easily discernible by the hindwing being quite brown with an inconspicuous stigma; forewing light brownish violet with a light lilac tinge, the veins strewn black and white; transverse lines as in *kearfotti*, but without white dots; a grey subterminal shadow is particularly distinct between 2 and 4. 1 ♂ from the Rio Dagua (Colombia) in the Berlin Museum.
- lissa*. **H. lissa** Drc. (155 g) is easily recognizable: forewing straw-coloured with a large black discal spot; the dark brown collar brightly contrasts with the forewing. Peru, Bolivia.
- unimacula*. **H. unimacula** Dyar (= *furina* Dogn.) differs from *lissa* in the pinkish-brown forewing being finely strewn darker; transverse lines dark brown, bordered with yellowish ochre on the averted sides; the large black discal spot is somewhat more obsolete in the ♀; 2 blackish dots connected by a shadow are in the centre of the marginal area. Hindwing dark brown with a large, not contrasting stigma. Guiana.
- ursara*. **H. ursara** Schs. is nearest to *unimacula*; body reddish-brown, white hair on the vertex, ventrum reddish-white. Forewing reddish fawn, strewn with light reddish-yellow; antemedian line slightly bent, reddish ochreous, distally bordered with reddish-brown like the postmedian line which extends 3 mm before the apex to the centre of the inner margin; an oblique black spot at the cross-vein; the ends of the veins finely strewn with white, subterminal irregular feeble shading between them. Hindwing whitish, dusted with fawn-colour, stigma not darker. Expanse of wings: 45 mm. Panama (Chiriqui).
- leucospila*. **H. leucospila** Wkr. (155 g). Forewing coloured and marked like the preceding species, but the discal spot is smaller and indistinct. Hindwing yellowish-white, veins and margin darkened reddish-yellow, with a brightly contrasting stigma. Amazons (Santarem). — f. **nivosa** Dogn. (155 g) differs from the type in the purely white hindwing with scarcely darker veins and stigma. Expanse of wings: 50—53 mm. Ecuador.
- pohli*. **H. pohli** Schs. Hindwing white as in *nivosa*, veins and margin broad red-brown, stigma dark brown. Forewing reddish-yellow, dusted dark olive, transverse lines yellowish with black vein-dots, the exterior one

from the apex to the centre of the inner margin; a round dull grey spot at the cell-end, shaded grey inside behind the cell. Brazil (São Paulo).

H. sericilinea Schs. (155 h) is presumably allied to *leucospila*; forewing light reddish-yellow with a *sericilinea*. silky gloss, finely strewn reddish-brown, costal margin orange, transverse lines orange-brown, the posterior one shaded greyish-brown inside, lighter outside, 2 subterminal dots below the centre; a small brown spot at the cell-end is surrounded with a darker colour; fringe dark orange brown. Hindwing whitish, inner margin and base of fringe brownish ochreous, no stigma. Collar yellow. Brazil (Petropolis).

H. buckleyi Dr. Forewing reddish-brown, strewn darker with a dark brown ring-macula; transverse *buckleyi*. lines dark brown, the exterior one from the apex to the centre of the inner margin. Hindwing light reddish-brown. Ecuador.

H. vecina Schs. (155 h). Forewing light red-brown, strewn with white, with 2 fine dark red-brown *vecina*. transverse lines bordered with ochre, then white on the averted sides; subterminal darker shading, fringe dark brown; a fine oblique dark streak at the cell-end. Inner margin somewhat dentate near the base. Hindwing and stigma light brown. Mexico, Venezuela.

H. colombia Dyar (155 h). Forewing reddish-brown, strewn darker, with dark brown transverse lines, *colombia*. the interior one fine, the exterior one thicker, ending in a blackish apical shadow from which an indistinct blackish undulate line proceeds; an oblique blackish streak at the cell-end. Hindwing brown, stigma large, but of the same colour. Colombia.

H. cadmioides Dogn. (155 h) is very similar to *cadmia*, but somewhat darker and hindwing with a stigma; *cadmioides*. forewing greyish ochreous, strewn with red-brown, the brown veins strewn with white, the dark brown transverse lines shaped as in *colombia*, an undulate line behind the postmedian line. Hindwing yellowish-white, brownish at the margin, stigma brown. Expanse of wings: 36—39 mm. Amazons.

H. striata Schs. (155 h) resembles *cadmia* still more, but the forewing is somewhat more yellowish with *striata*. a slight bronze gloss, the veins much broader striped brown, interrupted in the course of the transverse lines which are olive brown, bordered with reddish-white on the averted sides; inner margin almost straight. Hindwing white, veins and distal margin reddish-brown, stigma absent. Expanse of wings: 42 mm. Brazil (Novo Friburgo).

H. cadmia Guen. (= *obliquilinea* Wkr.) (155 i). Forewing greyish-brown, strewn with reddish-brown, *cadmia*. the veins finely striped dark brown, transverse lines dark brown, somewhat lighter on the averted sides. A feeble dent at the inner margin. Mexico.

H. congrua Dogn. is very similar to *cadmia*, the postmedian line ends a little more distantly from the *congrua*. apex, the forewing is not dentate at all. Ground-colour of a somewhat pink tint. Expanse of wings: 38 mm. Amazons.

H. aroensis Schs. Forewing with a stronger dent at the anal angle and before the centre, colour reddish- *aroensis*. brown dusted with lilae as far as the postmedian line, the fine interior transverse line is undulate, the exterior line is stronger, dark brown, distally lighter and finely marked dark at the veins. Hindwing white, veins, distal margin and stigma light red-brown. Expanse of wings: 35 mm. Venezuela.

H. manora Schs. is distinguished by the woolly hair on the forelegs of the male; forewing dark brown, *manora*. dusted violet as far as the posterior transverse line which is dark violettish-brown, the indistinct curved anterior line is reddish-brown; 3 small dark spots in a curved row at the cell-end; inner margin straight. Hindwing smoky grey, brownish at the distal margin. Stigma dark brown. Expanse of wings: 36 mm. French Guiana.

H. laurentina Schs. Forewing brown at the base and distal margin, lilae brown between them; instead *laurentina*. of the anterior transverse line black and grey vein-dots, the posterior dark red-brown transverse line is double, it begins at the blackened apex and extends into the incision before the dent, the inner margin itself is fine black. Hindwing whitish, inner and distal margins light reddish-brown, stigma dark brown. Expanse of wings: 39 mm. French Guiana.

H. ceiba Schs. Forewing reddish-brown, dusted lilae, the anterior transverse line replaced by 3 black *ceiba*. dots; the dark brown postmedian line extends from the blackened apex to the centre of the inner margin, and is dotted black on the veins, bordered with lighter brown outside; inner margin cut out and dentate. Hindwing whitish, brownish, veins and margins as well as stigma darker. Costa Rica.

H. cinnoma sp. n. (155 i). Forewing broad, inner margin slightly convex, without a dent or indentation; *cinnoma*. colour cinnamon-brown with a slight lilae reflection; the interior brown transverse line very feeble, the exterior one very strong, straight out of the slightly blackened apex to the centre of the inner margin, purple brown, lighter yellowish outside, narrowly and indistinctly shaded purple grey inside; shadow at the cell-end very indistinct. Hindwing brownish-white, lighter towards the base. Female antennae shortly pectinated. According to a female from Novo Friburgo (Brasil).

- flava*. **H. flava** Schs. (155 i) has longer wings; forewing bright yellow, dusted red-brown at the inner margin and behind the postmedian line, strewn with lilac between the cell and the submedian vein; interior line straight, dark brown, white outside, the exterior one from the darkened apex, ending at the inner margin near the interior line, bordered with white inside; a reddish-brown shadow at the cell-end, a black dot above it and a little before it. Hindwing whitish, the inner margin, distal margin and stigma reddish-brown. Expanse of wings: 47 mm. British Guiana.
- semililacea*. **H. semililacea** Dogn. has only an oblique red-brown postmedian line bordered with light outside, the wing before it light reddish-yellow at the costal margin, light lilac below it, the marginal area behind it light, chestnut-brown; a very fine brown streak at the cell-end; hindwing light brown. Expanse of wings: 32 mm. Amazons.
- teffea*. **H. teffea** Schs. (155 i) is not allied to any species known. Head and collar cinnamon-brown with a white band between the antennae. Thorax and base of abdomen light reddish cinnamon, abdomen above silvery greyish-brown, whitish beneath. Forewing reddish light brown with a silky gloss, the marginal area broad brown, costal-marginal part light reddish cinnamon like an oblique band from the base to the anal angle; a darker shadow in the cell and below it as far as the postmedian line; an indistinct dark spot at the cell-end; only one fine double transverse line is present, extending before the apex parallel to the distal margin to the inner margin. Hindwing of the only ♀ described so far brownish cinnamon. The figured ♂ from Villavicencio (Colombia) I range here with reservation. The ♀ from Teffé, Amazons.
- ruizi*. **H. ruizi** Dogn. (155 i) is easily recognizable: forewing brownish ochreous with 3 straight, almost parallel red-brown transverse lines, the interior one orange ochreous inside, the two exterior ones — the 3rd being the subterminal line! — orange ochreous outside, the subterminal line with a small interruption above the anal angle; a brown streak at the cell-end. Hindwing brownish-white, stigma contrastingly brown, fringe white. Ecuador, Bolivia.
- indigna*. **H. indigna** Schs. (155 i). Forewing light brown, the dark veins strewn with lilac grey, with fine olive brown transverse lines; a dark spot at the cell-end, a smaller one above it farther basad; the straight subterminal line of *ruizi* is merely a shadow here. Hindwing reddish-yellow, distal margin dark violettish-brown, the stigma not contrasting. This species is also allied to *transducta*, the inner margin sinuate and dentate. Expanse of wings: 40 mm. French Guiana.
- subdigna*. **H. subdigna** Dyar is very closely allied to *indigna*, but separated by the entire absence of the subterminal line; forewing light violettish-brown, median area and anal angle somewhat lighter, the margin above it shaded darker. Stigma not contrasting. French Guiana.
- buscki*. **H. buscki** Dyar (156 a) is likewise very similar to *indigna*, but the hindwing much lighter, almost white, so that the stigma is very conspicuous; thorax with a slight pink tint. Panama.
- corema*. **H. corema** Schs. (156 a) is also allied to the preceding species; forewing lilac brown, the dark brown transverse lines are reddish-yellow outside, the two small black spots at the cell-end more distinct, the veins partly strewn blackish and light brown, feeble traces of a subterminal shadow. Hindwing light brown, darker at the distal margin, stigma contrastingly brown. Costa Rica.
- daguensis*. **H. daguensis** Dogn. from the same group is distinguished by light reddish-brown, basally whitish hindwings and an inconspicuous stigma; forewing also more reddish-brown, somewhat lighter at the anal angle, the brown transverse lines bordered with yellowish ochre; veins of marginal area greyish-brown. Undulate line indistinct. Expanse of wings: 38 mm. Colombia.
- domingonis*. **H. domingonis** Dyar was described according to a female, and may therefore not be correctly ranged here; forewing lustrous dark bronze brown, strewn with violettish grey, the transverse lines feebly lighter, the anterior one bent and angled on the folds, with black vein-dots, the exterior one straight, with black vein-dots on the inside; the large cell-end shadow is somewhat trilobate; a feeble undulate linear shadow before the margin. Hindwing brown, lighter towards the base. San Domingo.
- refuga*. **H. refuga** Dogn. (156 a) also belongs yet to the group of *indigna*. Forewing red-brown with a violet tint and lighter dusting, with a darker faded cell-end dot and 2 lighter transverse lines; the marginal area behind the exterior line is somewhat lighter with a dark undulate linear shadow. Hindwing whitish, veins and margin brownish, stigma present. Expanse of wings: 41 mm. French Guiana.
- moresca*. **H. moresca** Schs. Forewing brown, dusted violettish-grey at the costal and inner margins and in the distal-marginal area, transverse lines light, shaded darker brown on the sides facing each other, the interior line slightly bent, with small black subcostal spots, the exterior one somewhat curved; a large dark oblique spot at the cell-end. Hindwing whitish, veins and margin brownish. Only the ♀ is known. British Guiana.
- triopas*. **H. triopas** Dogn. Forewing chestnut-brown with a coppery gloss, dusted violettish-grey in the inner-marginal half, with 2 blackish-brown transverse lines, the interior one angular, the exterior one very finely

dentate on the veins as in *moresca*. Hindwing white, brownish at the margin with a contrasting stigma. Also allied to *velva*. French Guiana.

H. clarki Schs. (156 a) is a large reddish-yellowish brown species with fine olive brown transverse lines *clarki*, bordered with reddish-yellow on the averted sides, with a large black spot at the cell-end, united with a smaller subcostal one above it; veins finely strewn grey; subterminal shadow indistinct. Hindwing brown, stigma also brown. Mexico, Costa Rica.

H. siderea Schs. Forewing reddish-brown dusted with grey, the outermost costal margin white, transverse lines dusted with whitish on both sides, with white vein-dots and black-strewn and broadly white-striped veins of the marginal area, strewn with reddish-brown, subterminally spotted blackish-grey; distal margin deep yellow, inner margin slightly cut out and dentate. Hindwing blackish-brown, fringe yellowish-white. Costa Rica. *siderea*.

H. serana Schs. Forewing light reddish-yellow, dentate at the inner margin, the interior line very feeble, with three black vein-dots, the exterior line red-brown from the apex to the centre of the inner margin, yellowish outside, with black vein-dots, slightly incurved in the lower half; a dark dot at the cell-end. Hindwing white, veins, distal margin, and stigma reddish-brown. Expanse of wings: 35 mm. Venezuela. *serana*.

H. liboria Schs. is near *modesta* from which it differs in the different colouring and the subbasal line. Forewing light reddish-cinnamon, strewn with brown with reddish-ochreous lines, an undulate excurved subbasal line is present; a thick brown streak at the cross-vein, and 2 small spots, one subcostally before it, the second behind it at the origin of 6; postmedian line remote from the apex, incurved towards the inner margin, a feeble dark subterminal shadow behind it. Hindwing light reddish-yellow, a fawn-coloured shadow along the inner margin. Stigma brown. Expanse of wings: 50 mm. French Guiana (St. Laurent). *liboria*.

H. modesta Btlr. (156 a) is a very common large species with red-brown forewings shaded darker in the costal-marginal halves, with fine dark transverse lines bordered with light on the averted sides, of a somewhat curved course; 2 small blackish spots obliquely above each other at the cell-end. Hindwing scantily scaled feebly brownish, somewhat darker on the veins and margin, with a scarcely conspicuous stigma. Mexico. *modesta*.

H. transducta Wkr. (156 b) is smaller than *modesta*, otherwise very similar, separable by the costal margin not being shaded darker; forewing somewhat broader, more brownish-grey, shaded blackish in the inner-marginal third excepting the light anal angle, on the whole strewn somewhat more whitish. Hindwing as in *modesta*. Mexico. *transducta*.

H. climaca Schs. belongs to the *transducta*-group. Anterior body cinnamon-brown, intermixed with white hair; forewing light brownish cinnamon, shaded darker in the median area below the cell as far as behind the postmedian line, costal margin narrowly white as far as the postmedian line; a small black and white subbasal spot below the cell; lines light reddish-yellow, shaded darker on the sides facing each other, the anterior one vertical, the posterior one from before the apex to close behind the centre of the inner margin; dark subterminal shading from the costal margin to vein 2, veins white, strewn with blackish-brown. Hindwing white, margin narrowly dusted brownish-cinnamon, stigma of the same colouring. Expanse of wings: 34 mm. Mexico to Panama. *climaca*.

H. dentata Dogn. (156 b) is very similar to *climaca*, but separated by the more deeply dentate inner margin of the forewing, a somewhat darker ground-colour of a more red-brown impression, strewn with yellowish, the transverse lines somewhat more distinctly dotted on the veins, hindwing more light brown. Expanse of wings: 38--39 mm. Described from Colombia. *dentata*.

H. nigrigutta Schs. (= yuntasa Dogn.) (156 b). Forewing dull brown with a straight inner margin, the fine yellowish transverse lines dotted black on the veins on the sides facing each other; a black spot at the cell-end with a smaller one above it and a little before it. Hindwing light reddish-yellow with a darker distal margin and a contrasting dark brown stigma. Expanse of wings: 42 mm. Bolivia. *nigrigutta*.

H. castanea Dogn. (156 b). Forewing chestnut-brown with a more yellowish tinge than in *nigrigutta*, transverse lines rusty brown, bordered with yellowish on the averted sides, with black vein-dots, the black cellular dots much less prominent; veins of marginal area somewhat lighter. Hindwing brown, yellowish towards the base, stigma absent. Expanse of wings: 52 mm. Colombia. *castanea*.

H. castaneoides sp. n. (157 a) is very similar to *castanea*, red-brown, the transverse lines the same, but without any black vein-dots, the veins of the marginal area blackened and strewn with white, the black discal dots very intense, connected by a bar. Hindwing brown, stigma brown. 1 ♂ from West Colombia (Rio Micay); type in the Coll. NIEFELT, taken in February-April. *castaneoides*.

H. trinubila Guen. (156 b) is a larger species very similar to *modesta*; forewing brown, not shaded costally, with the same transverse lines and 3 thick black triangularly arranged dots at the cell-end, *trinubila*.

often a fourth in the middle subcostally; somewhat darker subterminal clouding; hindwing as in *modesta*. Brazil.

joinvillia. **H. joinvillia** Schs. is allied with *dentata* and *postica*; anterior body reddish-brown mixed with white, abdomen above brown. Forewing lustrous yellowish reddish brown, the dark veins strewn with white like the whole wing; inner margin deeply lobate; transverse lines brown, bordered with reddish-yellow on the averted sides, the anterior one straight, the posterior one distant from the apex as far as close behind the inner-marginal dent; the space behind it darker as far as the margin, undulately defined outside; 3 small indistinct dark spots in the disc. Hindwing whitish, suffused with brownish cinnamon with a bronze gloss, stigma darker brown. Expanse of wings: 40 mm. Brazil, Joinville.

postica. **H. postica** Maass. Forewing light yellowish-brown with brown transverse lines bordered with white on the averted sides, a brown lunar spot at the cell-end is composed of 3 blackish connected dots; dark subterminal clouding forms three large spots. Hindwing whitish, yellowish greyish-brown at the distal margin. Described according to a ♀. From Ecuador.

barina. **H. barina** Guen. (= *illucens* Wkr.) is very much like *trinubila* with the same brown ground-colour; transverse lines somewhat straighter, the exterior one more remote from the distal margin. Hindwing darker greyish-brown, the stigma of the same colour and therefore not prominent. Inner margin not dentate. Brazil.

longipennis. **H. longipennis** Schs. (156 c) is easily recognizable by the remarkably long and narrow yellow forewings; the distal margin is somewhat convex below the apex and of a very oblique course so that the anal angle is almost absent; transverse lines violettish-brown, the exterior one bordered with white inside, beginning with a black spot at the apex, the marginal area behind it brownish ochreous, somewhat lighter towards the apex; a thick brown and lilac streak at the cell-end, a small spot above it and a little before it. Hindwing purely white. Colombia, Guiana.

albulana. **H. albulana** Drc. (156 c) is one of the lightest species, forewing yellowish-white, the transverse lines reddish-yellow, bordered with a lighter colour, the exterior one with very fine red-brown vein-dots, the interior one strongly notched, often only indicated; 3 indistinct dots at the cell-end; forewing broad, a dent in the centre of the inner margin. Hindwing white, no stigma. Mexico, Costa Rica.

avangareza. **H. avangareza** Schs. is very similarly marked, but the forewing is dull brown, strewn blackish, the transverse lines light reddish-yellow, the interior one forms 3 bows. Hindwing white, light brown at the distal margin. Costa Rica.

olivenea. **H. olivenea** sp. n. (157 a). A very conspicuous species, median area and the basal two thirds of the inner margin lilac, velvety deep chocolate brown above it in the basal part and in the whole marginal area, the two colours defined by scarcely noticeable dark fine lines which are somewhat more distinct only in the inner-marginal part where they exhibit on vein 1 one white, black-edged dot on each side facing the other; the posterior line forms an obtuse angle distally on vein 2, so that from here both the lines extend almost parallel to the inner margin; an oblique brown streak at the cell-end. Hindwing light brown, darkened at the margin. According to 1 ♀ from São Paulo de Olivença in the Berlin Museum coll. Stgr. A considerably lighter smaller ♂ from Villavicencio presumably belongs to this ♀; its hindwing is white, the margin and stigma narrowly light brown.

crassa. **H. crassa** Schs. (156 c). Forewing very dark red-brown, without a dent at the inner margin, narrowly strewn with grey; only a black postmedian transverse line edged with dark grey is distinctly present, extending down from the fourth fifth of the costal margin; the indistinct interior line is angled in the middle; an extinct dark spot is at the cell-end. Hindwing whitish, veins, distal margin and stigma dark brown. Expanse of wings: 37 mm. French Guiana.

angulinea. **H. angulinea** Schs. (= *angulata* Dogn.). Forewing violettish-brown, the veins strewn dark and reddish-yellow; the dark brown transverse lines are bordered with reddish-yellow on the averted sides, the anterior one is undulate, the posterior one very angular on the middle radial vein; darker shadowy spots at the cell-end and subterminally between the veins. Hindwing whitish, shaded brown at the distal margin. Bolivia.

taperinha. **H. taperinha** Schs. is very near to *angulinea* from which it differs in the undulate-dentate margin. Forewing light brownish cinnamon, browner at the inner margin, costal margin and median area strewn white; traces of an undulate subbasal line, the anterior transverse line from the centre of the costal margin, light brown, somewhat white above inside, somewhat undulate, with a black dot on vein 1, a yellowish patch in the cell behind it, a dark ring at the cross-vein, and a small spot above it; the postmedian line before the apex white, angled on 7, then brownish, cut by the veins which are red-brown outside, strewn with white; darker subterminal shading, expanded below 4 and 3. Fringe dotted white. Hindwing brownish cinnamon, base of cell and costal margin whitish. Expanse of wings: 35 mm. Amazons (Taperinha).

commentica. **H. commentica** Schs. (156 c) is very similar to *taperinha*; forewing grey, strewn light brown, brown at the distal margin, with a dark grey spot at the cell-end; the interior transverse line is very indistinct, the posterior line begins at the second third of the costal margin and is sharply angled on the upper radial vein from where it

extends finely undulate, almost parallel to the margin; the brown marginal shadow is bordered above the upper median vein by a darker brown shadow. Hindwing reddish-yellow, greyish-brown outside. The ♀ has pectinated antennae, that of *angulinea* plain ones. Expanse of wings: ♂ 39, ♀ 41 mm. Colombia, Guiana.

H. reyburni Schs. is allied to *commentica*; forewing reddish olive, abdomen brownish sand-coloured. *reyburni*. Forewing whitish in the basal area, strewn with brown, with an undulate dark subbasal line, a brownish oblique shadow behind it; the fine black antemedian line is deeply undulate-dentate; median area behind it whitish, strewn brownish cinnamon above the inner margin; a small blackish-brown spot at the cross-vein, and a larger one each at the inner margin before and behind the postmedian line; marginal area dusted brown with dark white-strewn veins. Hindwing dull brownish. Expanse of wings: 35 mm. Amazons (Teffé).

H. scalata Dogn. (156 d) is very easily recognizable by the scalariform course of the postmedian line; *scalata*. forewing brown, dusted yellowish, the darker brown transverse lines bordered with yellowish ochre and marked by dark vein-dots; 2 black dots obliquely above each other are at the cell-end; a dark subterminal shadow. Hindwing yellowish-grey, brownish at the distal margin, without a stigma. Expanse of wings: 41—45 mm. Colombia.

H. jovita Schs. is unlike any other species. Anterior body purple brown, vertex white, abdomen *jovita*. brownish. Forewing brownish violet, suffused with cinnamon-brown at the base and inner margin, with cinnamon-brown lines, the anterior one indistinct, undulate, vertical, the exterior one curved from near the apex to the submedian fold, darker purple outside; a black and light brown spot at the cell-end; inner margin rounded near the base. Hindwing white, dusted brownish towards the margin, with a dark brown stigma. Expanse of wings: 35 mm. Amazons (São Paulo de Olivença).

H. truncata Schs. (156 d) is at once discernible by the truncate apex; forewing lustrous dark brown, *truncata*. costal margin black; interior transverse line dark grey, followed at the inner margin by a reddish-brown, distally dark grey shadow; the exterior line is marked by a curved row of vein-dots with an indistinct olive brown shadow in the middle behind it; a large oblique reddish-brown oval at the cell-end, a broad dark shadow before the apex at the costal margin. Hindwing dark brown, whitish in the disc, with a large dark stigma. From Guiana and Colombia.

H. undilinea Schs. Forewing olive grey, the exterior transverse line, a submarginal shadow, a large *undilinea*. anal spot and a basal spot below the cell are reddish-brown, the undulate transverse lines dark brown; a broad oblique dark spot at the cell-end; inner margin straight. Hindwing dark brown. Expanse of wings: 35 mm. French Guiana.

H. trapezina sp. n. (156 d). The reddish-white ground of the forewing is densely strewn with red- *trapezina*. brown; both the notched anterior transverse lines dark brown below the median vein, lighter lilac whitish on both sides, yellowish-white above the median vein; an oval reddish-yellow indistinct spot behind the antemedian line in the cell; the postmedian line forms almost a right angle on the uppermost radial branch and is flatly undulate, dark brown, yellowish-white outside, with hardly any brown towards the costal margin; the cell-end shadow and subterminal shadow are broad, fadedly darker. Hindwing whitish, veins and margin brownish. Described from a female from Marcapata (Peru); type in the Museum SENCKENBERG.

H. metallescens Schs. (156 d) has iridescent golden brown forewings, the two first thirds of the costal *metallescens*. margin reddish-yellow, the cell and the space behind it are whitish lilac; a brown streak at the cell-end; 2 black double dots below the apex, the dark brown transverse lines are rudimentary, the posterior one only marked by a brownish ochreous spot bordered with violet on both sides; inner margin dentate, cut out before the anal angle. Hindwing whitish, veins and margin brownish, stigma golden brown. Expanse of wings: 39 mm. British Guiana.

H. vinicosta Guen. (157 d) is somewhat similar, well distinguished by the white collar; forewing metallic *vinicosta*. olive brown, broadly reddish at the costal margin, violettish grey in the cell, not distinctly defined against the dark inner-marginal part, the two colours gradually warming into each other. From Brazil.

H. meona Cr. (= *splendens* Mschlr.) (156 d) is bronze yellow in the basal and marginal areas, dusted *meona*. with a faded violettish grey in the median area, lighter in the costal-marginal part, the two colours separated by the dentate blackish transverse lines; a large dark spot at the cell-end, subterminal shadowy spots distinct at the costal and inner margins, similar shading also at the inner margin before the postmedian line. Hindwing white with a dark stigma. — CRAMER figures the larva of it: a green insect with violettish-brown saddle-spots on the dorsum, extending on the 6th and 9th segments down to the abdominal legs and bordered outside with black, then with white; between the 4th and 5th segments, and on the 11th, one short yellowish cone each. Guiana.

H. sabis Guen. (= *ania* Drc.) (156 e) exhibits a remarkably triangular shape of the wings, almost con- *sabis*. cavenly cut out at the distal and inner margins; whitish-grey, finely strewn brown, a brass lustre in the inner-marginal and postmedian areas, the margin remains narrowly light grey; darkest is the bronze colour in a basal

ray along the lower cell-margin and subterminally; transverse lines notched, the exterior one almost only marked by vein-dots; indistinct blurred dots at the cell-end. Hindwing white with a distinct dark brown marginal line and stigma. Very widely distributed from Mexico to Peru, Bolivia and Brazil.

deornata. **H. deornata** Wkr. (= *walkeri* Schs.) (156 e) is marked like *sabis*, but the colour is a monotonous brown with a slight bronze shine, hindwing dusted brown. Mexico.

zula. **H. zula** Schs. (156 e) is very similar to *deornata*, but the female has pectinated antennae, and the interior transverse line is more angular; forewing greyish-brown with a silky gloss, lighter in the costal-marginal part, a dark brown shadow from the lower cell-angle to the inner margin, dark brown shadowy spots are before the distal margin. Hindwing greyish-brown, whitish in the disc, stigma greyish-brown, not contrasting. Costa Rica.

losa. **H. losa** Drc. (= *lepidula* Schs., *carmelita* Maass.) (156 e). Forewing light violettish-brown, strewn with red-brown; behind the undulate brown interior line follows a darker shadow bending down towards the inner margin as far as the anal angle, and behind the indistinct dark cell-end streak a brown shadow to the distal margin, which widens here from the apex to the inner angle; a dentate subterminal shadow behind the post-median line which is composed of black vein-dots. Hindwing whitish, veins, margin, and stigma brown. Costa Rica to Colombia.

pallidula. **H. pallidula** Guen. (156 e) is one of the most common and widely distributed species; forewing light yellow with a feeble brass lustre, dusted with violettish-brown in the inner-marginal half and along the distal margin; the transverse lines only coherent below the cell, the interior one is quite absent above it, the exterior one marked by vein-dots which are partly white-centred, 3 white dots in the cell-end. Inner margin strongly dentate. Head white, thorax violet. Hindwing light brownish, without a stigma. Mexico to Brazil. — The larva is chestnut-brown with 2 yellow dorsal bands ending in a red cone on the 11th segment; 3 white lateral lines, in the lowest are the black spiracles, the last segment is black mixed with white. It pupates between leaves which it spins together.

oralis. **H. oralis** Schs. (156 f). Forewing silvery grey, strewn darker, the fine light brown dentate transverse lines marked on the veins by dark dots; a large oval yellow spot in the cell is crossed by the interior line; distal margin shaded darker grey. Hindwing white, brownish on the veins and margin, stigma dark brown or light grey. Brazil.

egregia. **H. egregia** Dogn. Forewing chestnut-brown with a pink tinge and a bronze shine, with 2 faded, more yellowish transverse bands scarcely contrasting with the ground-colour, an interrupted one in the middle and a curved one subterminally; the transverse lines between these bands are formed by black vein-dots. Hindwing light bronze brown, whitish basally. Ecuador.

aena. **H. aena** Dogn. Greenish olive with a bronze shine, lighter basally and at the distal margin, with 2 darkened bands to the margin and anal angle; transverse lines red-brown with black, white-centred vein-dots, also a subterminal row of hardly visible vein-dots and 2 indistinct blotches at the cell-end; inner margin twice deeply dentate and cut out before the anal angle. Hindwing greyish-white, veins and margin darkened, without a stigma. Expanse of wings: 46 mm. Colombia.

oleagina. **H. oleagina** Dogn. resembles *aena* and *egregia*, less bronzed, and with a contrasting brown stigma on the white hindwing which is brownish at the margin; a reddish-yellow spot mixed with violet is before the exterior row of dots in the inner-marginal excision, the colour being otherwise greenish olive as in *aena*. South-Eastern Peru.

stigmata. **H. stigmata** Dogn. (156 f). Forewing coloured like *aena*, hindwing somewhat lighter and with a brown stigma which is absent in *aena*; also very similar to *nigricosta*. Expanse of wings: 45 mm. Bolivia.

nebulosa. **H. nebulosa** Schs. Forewing reddish-yellow, strewn with brown, shaded grey basally and along the inner margin, from a grey cell-end streak a grey shadow extends to the distal margin and as far as the apex; transverse lines marked by rows of dots, a dentate brown line behind the exterior line; inner margin not dentate. Hindwing brown, margin and stigma still darker. Expanse of wings: 35 mm. French Guiana.

flavescens. **H. flavescens** Schs. (156 f). Forewing bright dark yellow in the basal third and along the costal margin as far as the apex, the rest lilac brown, apically strewn with black and grey; 2 black dots before the centre are connected by a fine violet shadow, a dark grey spot at the cell-end with a smaller one above it and before it; the exterior transverse line is composed of black and grey vein-dots connected at the inner margin by a fine dark line; the excision before the anal angle is bordered with brown. Hindwing whitish, yellowish-brown at the margin. Similar to *pallidula*. Expanse of wings: 40 mm. French Guiana.

punctata. **H. punctata** Dogn. (157 d) is a large yellowish-brown species, dusted dark brown in the median area especially at the costal margin, the rows of black dots broadly bordered with yellowish on both sides, a dark notched shadow before the light undulate line; 2 black dots at the cell-end. Hindwing whitish with a brownish margin, without a stigma. Ecuador, Colombia. — **panamensis** f. n. (157 d) has constantly darker brown hindwings. Panama.

H. latior *sp. n.* (157 b) is very similar to *punctata*, but larger and, above all, the wings are much *latior*. broader, more unicoloured red-brown, with the same marking; easily separable by the quite dark brown hindwings. Several ♂♂ from St. Antonio, Colombia; type in the Berlin Museum.

H. celia *Schs.* Forewing red-brown with a silky gloss, dusted with violet excepting the distal margin; *celia*. the anterior brown fine transverse line is straight, somewhat dotted on the veins, the exterior one similar; a fine black streak at the cell-end; inner margin dentate and cut out. Hindwing brown, without a stigma. Costa Rica.

H. nupera *Dogn.* Forewing dark red-brown at the base and margin, metallic violet in the median area *nupera*. with a red-brown discal spot, transverse lines not definable. Hindwing light yellowish, veins and margin brownish, stigma contrastingly brown. Expanse of wings: 45 mm. Amazons (Olivença).

H. constellata *Dogn.* (156 f). Forewing glossy deep violettish-brown, the transverse lines composed *constellata*. of rows of metallic greenish-white dots, the exterior row of which is double, the subterminal line is also represented by such dots, and at the cell-end there are 2 spots of the same colour. Hindwing brown with darker veins and margin and a not contrasting stigma. Mexico to Costa Rica and West Colombia. — f. **albescens** *albescens*. *Dogn.*, from Guiana, Peru, Bolivia and the Amazons, has whitish hindwings. Antennae of ♀ pectinate.

H. sparsipennis *Wkr.* (= *canosparsa* *Wkr.*) (156 f) is very similar to *constellata* and also to *muscosa*, *sparsipennis*. forewing greyish-brown with a fine white costal margin, marked as *constellata*, but besides with a large spot of white scales below the base of the cell; hindwing without a stigma. From Panama through Guiana to Brazil.

H. coatina *Schs.* (156 g) is coloured and marked like *muscosa*, but it has a white costal margin of *coatina*. the forewing and the white-strewn spot below the base of the cell, as in *sparsipennis*; forewing purple brown, the vein-dots and subterminal dots are white. Hindwing dull light brown, without a stigma. Expanse of wings: 40 mm. Guatemala to Colombia.

H. muscosa *Schs.* (156 g). Forewing brown as in the preceding species, with a silky lustrous lilac shadow *muscosa*. from the lower cell-end to the distal margin near the anal angle; the interior transverse line is marked by 3 white vein-dots, the posterior one by a double white dentate line followed by a short third row before the apex. Inner margin with a strong dent. Hindwing light brown with darker veins, without a stigma. Mexico to South Brazil.

H. evanescens *Dyar* seems to be allied to *muscosa*, but the inner-marginal dent much less strong, *evanescens*. entirely absent at the anal angle; forewing monotonously lustrous purple brown, the dentate transverse lines marked by black vein-dots, the interior ones bordered with yellowish ochre towards the base, the exterior one slightly strewn white inside and with white vein-dots; darker clouding at the cell-end, a darker shadow at the margin, the middle of which reaches the postmedian line. Hindwing dark brown. Only 1 ♀ from Panama.

H. poulsoni *Schs.* Forewing olive brown with a bronze gloss, violettish-grey at the costal margin, *poulsoni*. the interior black transverse line finely dentate, the exterior one replaced by small brown spots with 2 larger apical ones and an anal one behind them; a thick oblique black streak at the cell-end. Hindwing white, stigma light red-brown. Expanse of wings: 51 mm. British Guiana.

H. brunnea *Schs.* (156 g). Forewing brown, scantily strewn with grey, the rows of black vein-dots *brunnea*. forming the two transverse lines are connected by indistinct red-brown shading, an oblique dark shadow in the cell. Hindwing light brown, whitish basally, darker at the margin, without a stigma. Expanse of wings: 45 mm. Bolivia.

H. arbogasta *Schs.* is allied to *brunnea*, the inner margin of the forewing is only slightly excurved; forewing fawn-coloured with black lines, the anterior one intensified by black dots, a cinnamon-red shadow before it, the posterior line from before the apex, undulate, with black vein-dots, a broad cinnamon-red shadow behind it, somewhat less distinct between 5 and 2; a blackish streak at the cell-end, a dark shadow below it extends to the inner margin; a subterminal cinnamon-brown oblique shadow between 4 and the anal angle. Hindwing whitish, veins and margin broad reddish cinnamon, only the ♀ is known. Expanse of wings: 49 mm. Brazil (Rio Purus).

H. perbrunnea *Dogn.* differs from the very similar *brunnea* in the almost straight inner margin which *perbrunnea*. is sinuate in *brunnea*, with a basal excision; forewing more yellowish ochreous brown, in an oblique light with a reddish-violet shine, the transverse lines as in *arbogasta*, the postmedian dots thicker; discal shadow broad; subterminal shadow indistinct. Hindwing light brown, no stigma. Expanse of wings: 48 mm. Colombia.

H. princeps *sp. n.* (157 b). Head and palpi as well as collar rusty brown, frons white, thorax violettish-brown, abdomen greyish-brown. Forewing deep lilac brown with a silky gloss and strewn with bluish-white scales, most densely so at the costal margin; both the notched transverse lines dark red-brown, bordered with bronze yellow on the averted sides, the posterior line bordered with a pure white inside above the inner margin; a comma-shaped black streak at the cell-end, and a dot inwards above it; margin deeper purple brown; expanded in a triangular shape inwards between 2 and 4. Hindwing dark greyish-brown, the small and narrow

stigma of the same colour is only visible under the lens. 1 ♂ from the Rio Micay (West Colombia), type in the Coll. NIEPELT.

- amanda*. **H. amanda** Schs. resembles *muscosa*; forewing red-brown, with a violettish-grey reflection in the median area and in the anal area, the fine dark transverse lines with white vein-dots; cell-end shadow dark violettish-grey. Hindwing brown, lighter between the veins, no stigma. Mexico to Costa Rica.
- hidulpha*. **H. hidulpha** Schs. is unlike any other species. Anterior body red-brown with white spots on the vertex and mesothorax, abdomen brown. Forewing red-brown with a white costal margin, deeply lobate at the inner margin and cut out before the anal angle; anterior transverse line dotted white, posterior line composed of white lunules at the costal and inner margins, dotted between them, marginal area suffused with red. Hindwing and stigma brown. cell and base of costal margin whitish. Expanse of wings: 41 mm. Brazil, Rio Purus.
- conspirata*. **H. conspirata** Schs. (156 g). Forewing violettish-brown, narrowly olive brown at the margin, widened in the middle, with a fine white costal margin, the transverse lines marked by fine black and grey vein-dots, the interior line connected by an indistinct red-brown line, the posterior one towards the inner margin by a grey line; a narrow dark shadowy spot at the cell-end. Inner margin deeply sinuate and dentate. Hindwing brownish-white with darker veins, a narrow marginal shadow and stigma. Expanse of wings: 44 mm. Guiana to South Brazil.
- colorata*. **H. colorata** Dogn. (156 g) has the same long-dentate and deeply cut out inner margin as *conspirata* and is easily discernible by the purely white hindwing with an extremely finely brownish margin and a very much contrasting chestnut brown stigma. Forewing lustrous dark red-brown with a lilac reflection excepting the marginal area, a fine white costal margin, and 2 transverse rows of black, white-centred vein-dots; cell-end spot quite faded. The ♀ has pectinate antennae. Expanse of wings: 48–58 mm. Guiana, Amazons. Peru.
- gigas*. **H. gigas** sp. n. (157 b) is very closely allied to *conspirata*, but still much larger, with an expanse of up to 60 mm. Forewing of a deep purple brown, the two transverse rows of dots, formed of little heaps of white, black-edged scales, are accompanied on the averted sides by Pompeyan red bands, the exterior one distinctly undulate-dentate; the large triangular marginal spot with its point on vein 5 is bordered inside, between 6 and the costal margin, by a blackish subterminal band. Hindwing whitish only in the disc, broadly brownish at the margin and veins, so that the stigma is not very prominent. Hindwing and ventrum beneath white. 1 ♂ from Manaos. Coll. STGR. in the Berlin Museum.
- levana*. **H. levana** Drc. (156 h) is very similar to *colorata*, but its forewing is darker brown, not so reddish, the hindwing brown, not white; the type was described from Ecuador. Expanse of wings: 56 mm. — The
- amazonica*. race from the Amazons is: **amazonica** Dgn. distinguished by more intensely dusted lilac forewings with more prominent dentate transverse lines and whiter hindwings, only brownish on the veins and margin, and a better contrasting stigma.
- nigriplaga*. **H. nigriplaga** Schs. (156 h). Forewing brown; interior transverse line dark brown with black vein-dots, the costal-marginal spot being the largest, exterior transverse line black, dentate, but extending only from the apex to the middle radial vein and appearing only again above the sinuate inner margin and below the centre in 2 black vein-dots; a few brown and black spots apically behind it; a large irregular black spot at the cell-end and a small one above it. Hindwing brownish-white, veins and margin darkened. stigma dark brown. Expanse of wings: ♂ 39, ♀ 43 mm. French Guiana.
- cinescens*. **H. cinescens** sp. n. (157 b). Forewing light violettish-grey, with a slight brownish-yellow reflection in the basal and marginal areas; the anterior transverse line forms two bows and is dotted black on the veins, the posterior one sharply dentate, fine black. a small indistinct brownish spot in the lower cell-end; undulate line notched between 6 and the costal margin, shadowy brownish grey below it, enclosing at the inner margin with the postmedian line a trapezoid yellowish-brown small spot. Hindwing brownish. 1 ♀ from Muzo (Colombia) in the Berlin Museum.
- mutoca*. **H. mutoca** sp. n. (157 c) hardly resembles any other species; forewing dark red-brown, intermixed with bluish-white hair-scales, especially at the inner-marginal part, along the costal margin, on the blackish veins of the marginal area, and along the notched bronze brown transverse lines; a very large black indistinctly defined discal spot in the cell-end; subterminal line shadowy very near the postmedian line. more blackened in the apical spot. Hindwing greyish-brown, darker at the margin with an inconspicuous stigma. West Colombia between Tumaco and Pasto; type in the Berlin Museum.
- serrata*. **H. serrata** sp. n. (157 c). Forewing light violettish-grey, finely strewn black, the median vein and the notched transverse lines red-brown, the posterior one bordered lighter inside by the absence of strewing, more distinctly marked by black dots on the veins; 3 black dots at the cell-end; the postmedian line is bordered with rusty yellow outside above the inner margin and has here a black spot behind it; the undulate line is a sharply notched blackish shadowy line from the costal margin to vein 2, extinct below it. Hindwing brown, somewhat lighter towards the base, stigma scarcely noticeable. 2 ♂♂ from West Colombia (Tumaco). Berlin Museum.

H. cotto Dyar (156 h). Forewing broadly triangular with a strongly developed dent in the centre *collo.* of the inner margin and at the anal angle; forewing light purple brown with a bronze shadow in the lower half of the median area and from behind the cell to the anal angle, the undulate line is marked by a less distinct similar shadow; transverse lines fine, blackish, the interior one twice notched, the exterior one finely dentate; a distinct round black spot at the cell-end. Hindwing brown, lighter towards the base, with a brown but not contrasting stigma. Mexico.

H. punctilla Schs. (156 h). Forewing light reddish brown with black, undulate-dentate transverse lines, *punctilla.* the exterior one more distinct at the costal and inner margins; a red-brown spot at the cell-end with a smaller black one above it. Hindwing white, veins and margin reddish-brown, with a small red-brown stigma. Expanse of wings: 40 mm. Venezuela.

H. pagana Schs. has reddish-brown forewings finely strewn with dark grey especially in the median *pagana.* area, with a large black cell-end spot and quite indistinct transverse lines, the exterior one punctiform, small dark apical shadowy spots behind it. Hindwing white, veins and margin brownish, with a very much contrasting stigma. Expanse of wings: 45 mm. Paraguay.

H. alba Wkr. (156 h). Forewing very light greyish-white, strewn somewhat darker, with very indistinct *alba.* punctiform transverse lines, without a discal spot. Inner margin with a broadly triangular dent, without an excision. Hindwing white with a fine brown marginal line and veins, and an ablong reddish-brown stigma. Abdomen also reddish-brown. Mexico.

H. nigrescens Schs. (= *obliquiplaga* Dyar) (156 i). Forewing violettish-black with a brown distal *nigrescens.* margin, mixed with a somewhat reddish-brown colour at the base, with a dark oblique shadow from the cell to the distal margin; transverse lines dark red-brown, some whitish scales behind the exterior line at the apex. Inner margin deeply cut out before the anal angle. Hindwing dark brown. Costa Rica.

H. imitans sp. n. (157 c) is similar to *nigricosta*, but easily discernible from it by diaphanous white, *imitans.* somewhat opalescent hindwings with a narrow light brown margin and veins. Forewing duller brown, median area without a lilac shine; costal margin only very narrowly blackened, the undulate line without any white at the costal and inner margins, marked here as very faint grey shadows. 1 ♂ from the Rio Songo (Bolivia) in the Berlin Museum.

H. nigricosta Schs. (156 i). Forewing red-brown, a slight violet shine in the median area, with a *nigricosta.* broad black costal margin strewn with white, with dark transverse lines, the exterior one dentate, marked on the veins by dots; the undulate line is marked by a few white scales apically and above the anal angle; an oblique dark line at the cell-end, and a dark shadowy spot below the centre of the margin. Hindwing dull brown. Expanse of wings: 53 mm. Costa Rica.

H. phocas Schs. is near *nigricosta* from which it is separated by the different shape of the wings. *phocas.* Forewing brownish violet, dull violet at the costal margin strewn with bluish-white; anterior transverse line chestnut-brown with a white dot on vein 1; an oblique streak at the cross-vein; postmedian line punctiform, connected by a fine dentate line, shaded brownish outside above the inner margin; an oblique brown shadow in the centre of the margin. Hindwing whitish with a browner inner margin, veins and stigma. Expanse of wings: 40 mm. Amazons.

H. praxides Schs. differs from *phocas* in the white hindwing and has the same wing-contours as the *praxides.* following *eustalhia*. Anterior body cinnamon-red, forewing more reddish-brown with a dark grey costal margin strewn somewhat white, and a fine dark basal line; the fine brown antemedian line extends almost straightly to the inner margin, an oblique streak at the cross-vein; the postmedian line proceeds from before the apex, undulate-dentate, below 6 only as black and white vein-dots; a cinnamon-brown oblique shadow between 5 and 3, and a blackish-brown oblique subterminal shadow between 8 and 5. Hindwing white with a narrow cinnamon-brown margin and stigma. Expanse of wings: 42 mm. Brazil (Rio Purus).

H. eustalhia Schs. Anterior body reddish cinnamon. Forewing with a straight costal margin, a pointed *eustalhia.* apex, margin and anal angle in an oblique rounding as far as the base of the inner margin, reddish-brown, with an iron-grey costal margin and a mouse-coloured basal area, of the same colour is the median area bordered inside by the dark grey antemedian line, outside by an oval grey cell-end spot, and between 3 and the inner margin by the undulate postmedian line which is extinct between 3 and 5; instead of it there is an oblique cinnamon-brown shadow; an irregular grey subterminal shadow between the costal margin and 6, and a small spot before the anal angle. Hindwing white, inner margin sand-coloured grey, veins and margin narrowly cinnamon-brown, stigma deep brown. Expanse of wings: 45 mm. Brazil (Rio Purus).

H. singula Guen. (156 i) is a very large brownish violettish-black species, very finely strewn grey, *singula.* with dark dentate transverse lines and still deeper shadowy spots, one in the cell-end and one separated from it, extending to the anal angle. Hindwing greyish-brown. Mexico to Costa Rica.

H. violascens Guen. (= *singuloides* Dyar) (156 i) is very similar to *singula*, but the hindwing is more *violascens.* whitish, greyish-brown only on the veins, and the marginal shadow of the forewing is confluent in a line with the cellular shadow; transverse lines less distinct. Colombia to Brazil.

- sericita*. **H. sericita** Schs. Forewing violettish-brown with a silky shine, red-brown with a bronze lustre in the basal area and at the distal margin; only the dark brown postmedian line is distinct, some white scales apically behind it; an oblique red-brown streak at the cell-end, inner margin strongly dentate. Hindwing light brown. Expanse of wings: 44 mm. Colombia.
- micans*. **H. micans** Schs. (156 i) is a very large, monotonously red-brown species with a somewhat lilac shining median area edged by very fine black vein-dots instead of the transverse lines; a dark streak at the cell-end, a somewhat darker submarginal shadow. Hindwing whitish, scantily strewn with red-brown, stigma violettish-brown. Mexico.
- lilacina*. **H. lilacina** Dogn. Forewing dark red-brown with a bright violet reflection excepting the transverse lines and the white-strewn veins, the former with white vein-dots; 2 black dots obliquely above each other at the cell-end; some white scales subapically. Hindwing greyish-white, veins and margin darker, nostigma. Expanse of wings: 52 mm. Colombia.
- rufescens*. **H. rufescens** Wkr. (156 k) is a smaller species with yellowish red-brown forewings, somewhat lighter in the costal-marginal area, the transverse lines marked by black vein-dots, the anterior one strongly notched, a small faded spot at the cell-end; shadowy spots, often very indistinct, are at the inner margin behind the postmedian line, from the lower cell-end to the margin and subterminally above it. Hindwing white with a small reddish-brown stigma. Brazil.
- rufula*. **H. rufula** Dogn. is similar to *rufescens*, but the inner margin of the forewing is not dentate, but only slightly sinuate; forewing rusty reddish, with 2 rows of black fine vein-dots and similar shadowy spots as in *rufescens*; hindwing lustrous rusty reddish with a similarly coloured stigma, lighter in the female. — f. **vinosa** Dogn. is a female form, the forewing with a claret-coloured tint, with a shading along the inner margin between the rows of vein-dots, the posterior one of which is followed by a band of reddish strewing, while the subterminal shadow is absent. Expanse of wings: 40–47 mm. Amazons (Sao Paulo de Olivença).
- casiaclara*. **H. casiaclara** Dogn. is allied to the two preceding species; inner margin of forewing strongly dentate, with a deep excision before the anal angle; forewing monotonously light cinnamon brown, somewhat darker only at the cross-vein and in 2 subterminal shadows, with 2 rows of brownish-black vein-dots which are partly connected by dentate lines. Hindwing whitish, brownish towards the margin. Stigma cinnamon-brown. Expanse of wings: 38 mm. Amazons (Maués).
- metastigma*. **H. metastigma** Wkr. (156 k). Forewing dark brown, shaded, the two dentate transverse lines complete, marked by vein-dots. Hindwing brownish with a large dark brown stigma. Mexico.
- torva*. **H. torva** Schs. (156 k). Forewing reddish-brown with a yellowish reflection, marked like *metastigma*, but the anterior transverse line replaced by dots; a small brownish spot at the cell-end with a smaller subcostal one above it; the dark postmedian dots terminate at the inner margin in a large reniform brown spot edged with dark violet, the dent and the excision at the inner margin also bordered with dark violet; subterminal shadow light brown, dentate. Hindwing brownish-white, veins and margin darker with a still darker stigma. Costa Rica.
- velva*. **H. velva** Schs. Forewing monotonously light violettish brown with very feeble punctiform lines, with a shadowy spot behind the posterior line below the centre, and an indistinct dark cellular spot. Inner margin straight, without a dent or excision. Hindwing purely white, veins and margin narrowly reddish-brown, stigma contrastingly brown. Expanse of wings: 39 mm. Venezuela.
- soso*. **H. soso** Dyar (156 k). Forewing lustrous brassy brownish strewn with black especially in an oblique shadow of the median area; the fine black dentate lines are marked by vein-dots, bordered with lighter yellowish on the averted sides, with a large oval ring-spot at the cell-end; large roundish subterminal shadowy spots. Hindwing whitish, somewhat brownish at the margin, stigma dark brown. It resembles also *pagana*, though with more distinct lines and a less distinct discal luna. Mexico.
- quebra*. **H. quebra** Schs. Forewing reddish-brown with indistinct dotted transverse lines and an indistinct dark cellular spot. Hindwing reddish-brown, whitish basally, stigma brown. Expanse of wings: 42 mm. Venezuela.
- elphega*. **H. elphega** Schs. is near *quebra*, but the postmedian line is punctiform. Forewing reddish-brown with fine black lines, the anterior one with black vein-dots, the posterior one undulate-dentate, a narrow blackish shadow behind it between the apex and 6; a brownish line at the cross-vein and a black dot above it. Hindwing white, stigma and margin narrowly reddish-brown. Expanse of wings: 44–49 mm. French Guiana.
- monegonda*. **H. monegonda** Schs. differs from *elphega* in the blackish-brown costal margin, a somewhat different course of the lines, a blackish cross-vein streak, and a subterminal shadow between 5 and 2. Expanse of wings: 55 mm. Costa Rica (Guapiles).

nubilata Schs. (156 k) is similar to *metastigma*, but darker and the inner margin straighter, without a *nubilata* dent; forewing reddish-brown, median area somewhat darker, strewn with grey and lilac, transverse lines dark grey, broadly bordered with reddish-yellow on both sides, the exterior line punctiform, a reddish shadow behind it towards the inner margin, and a dark shadow before the margin in the lower half. Hindwing light reddish-brown, stigma brown. Mexico to Venezuela.

H. pernubila Dyar (157 d) is more monotonous than the very similar *nubilata*, the broad reddish-yellow *pernubila* borders of the transverse lines in the latter are very narrow here. Hindwing brown, whitish basad between the veins, with a large dark brown stigma. Mexico to Venezuela and Ecuador.

H. noctifer Schs. is very near *nubilata* and *pernubilata*, with a different copulation apparatus. Forewing *noctifer* brown with a silky gloss, basal area shaded slightly darker, also the median area except the cell; the brownish-black anterior transverse line is vertical, the posterior one from 3 mm before the apex to the centre of the inner margin, feebly dentate, with black and white vein-dots, a narrow cinnamon orange shadow behind it between 2 and the inner margin; the brownish-black subterminal shadow from the costal margin to 4, then interrupted inwards and extending obliquely to the margin below 2; a blackish-brown spot behind the postmedian line at the inner margin. Hindwing lustrous light brown. Expanse of wings: 44 mm. Costa Rica (Juan Vinas) to Colombia (Juntas).

H. turnina Schs. is allied to *subochraceum*. Forewing light brown, suffused with reddish, with brown *turnina* lines dotted black on the veins; subterminal shadow very indistinct, a fine cross-vein streak. Hindwing light brownish, somewhat darker at the margin with a deep brown stigma. Expanse of wings: 46 mm. Peru (Yahuarmayo).

H. subochraceum Wkr. (= *mora* Drc.) (157 a) is very similar to the two preceding species, darker, *subochraceum* larger, much more monotonously reddish violetish-brown, separated by the entire absence of the reddish-yellow borders of the transverse lines. Mexico.

H. vinvala Schs. is near *subochraceum*; forewing light brown with a silky gloss; the brown antemedian *vinvala* line indistinct, vertical, with darker vein-dots, the posterior one from near the apex, also with vein-dots, composed only of dots below 2; an indistinct dark oblique shadow before the centre of the margin and a fine dark streak at the cell-end. Hindwing and stigma monotonously yellowish reddish-brown with a bronze lustre, fringe white. Expanse of wings: 49 mm. Colombia (Palmira).

H. lotula Guen. together with the preceding species forms a group very difficult to differentiate, as *lotula* large as *subochraceum*, the transverse lines somewhat more distinct and more continuous, the anterior one almost straight, with a darker dentate subterminal shadow. Hindwing lighter than in *vinvala*. Venezuela to Brazil.

H. tulola Schs. Forewing more brownish-grey, the fine transverse lines black, the interior one undu- *tulola* late, the exterior one only coherent at the inner margin, otherwise punctiform. Hindwing light brown. Expanse of wings: 37 mm. Brazil.

H. rava Schs. (157 a) is more reddish-brown than *tulola*, the dentate subterminal shadow distinct, *rava* the inner margin almost straight. Hindwing light brown, veins and margin darker, scantily scaled basally. Costa Rica.

H. ravula Dogn. is much greyer, the lines more separated, the vein-dots white-pupilled, 2 dots at the *ravula* cell-end. Hindwing grey, the stigma less contrasting. Expanse of wings: 37 mm. Argentina.

148. Genus: **Hapigia** Gn.

A larger genus of rather conspicuous representatives with long slender forewings of a mostly brown colour and often large silvery spots at the cell-end, which however are not constant in the same species and may also just as often be absent. In distinction with the similar following genera, the antennae are only ciliated, nodular at the base, the palpi rather long, the middle joint hairy. Apex of forewing pointed, distal margin very oblique; vein 5 arises from the centre of the cross-vein or above it, 6 is stalked with the 4 lower subcostal branches, the areole being absent. Hindwing: veins 3 and 4 have the same origin, 6 is stalked with the subcostal vein, the costal vein is connected by a short bar with the subcostal vein near the base of the type.

Type of genus: *H. nodicornis* Guen.

H. nodicornis Guen. (157 e). Forewing deep red-brown with 5 blackish shadowy stripes extending from *nodicornis* above inside to below outside, reaching neither the costal nor inner margins as in *duponti*; the silvery spot in the centre is absent; the black apical shadow is dusted white outside; fine black double dots before the margin, a fine serpentiformly curved submarginal line before them. Hindwing greyish-brown, lighter yellowish towards the base, fringe lighter. Brazil.

H. duponti Schs. is allied to *nodicornis*; anterior body reddish-brown, abdomen grey. Forewing brown- *duponti* ish cinnamon, with 3 darker oblique shadows distally bordered with a faded lighter colour, the antemedian

one to the centre of the inner margin, the middle one to the margin on 2, the posterior one between the postmedian line and subterminal line on 3; the grey subbasal line indistinct; a small grey subcostal spot before the cell-end, 2 greyish-green spots below it, the upper one oblique, the lower one curved and produced on the median vein; a cinnamon line extends from the costal margin to the lower cell-angle and from here somewhat inwards towards the inner margin; the posterior transverse line with black and white vein-dots, and a white oblique spot behind it on 5, a whitish dentate line above it; 2 white subapical lunules strewn with greyish-green behind it, the subterminal line composed of small black lunules. Hindwing brown, fringe yellowish-white. Expanse of wings: 70 mm. Amazons (Amatura).

annulata. **H. annulata** Schs. (157 e) is allied to the preceding species, forewing lilac brown with 6 darker shadowy stripes extending obliquely downward outside and reaching neither the inner nor distal margins, the middle stripe interrupted by a long silvery spot filled with white; another less distinct preapical shadow is bordered outside by an irregular white line, a few black dots before the margin. Hindwing greyish-brown with blackish-veins. Costa Rica, Guiana, Brazil.

obliqua. **H. obliqua** Wkr. (157 e) resembles *annulata*, but the forewing is quite light yellowish red-brown, the 6 transverse shadows are very much narrower, so that they almost appear as broad lines; they begin close at the costal margin and are continuous to the inner margin; the silvery spot in the centre seems to be absent, but it is represented by a fine black linear marking; the fine blackish submarginal line is marked in the shape of very pointed W-markings, a fine blackish apical line is bordered with silvery white inwards. Hindwing brownish-grey. Colombia, Bolivia.

hollandia. **H. hollandia** Schs. (157 f) is easily discernible from all the species by the notched margin. Forewing light reddish purple brown with numerous darker oblique bands; a double silvery line at the cell-end. Hindwing brownish sand-coloured, fringe light reddish-yellow. Brazil (Rio Purus); also from the Rio Songo (Bolivia).

smerinthoides. **H. smerinthoides** Wkr. (157 f) is very much like *notha*, but the light reddish-brown forewing is not tinged with violet, the 3 brightenings are hardly noticeable as very indistinct more yellowish places; the fine darker lunular lines are arranged by twos and of a more distinct antemedian and postmedian course, the ground between them is not darkened olive; at the cell-end there is a large olive green reniform macula of an irregular triangular shape, partly strewn with bluish-white. Hindwing brownish-grey. Colombia, Bolivia, Brazil.

smerinthina. **H. smerinthina** Schs. resembles *smerinthoides*, but it has a smooth margin and it is lighter, reddish-yellow, with fine darker undulate transverse lines meeting in the centre of the inner margin; a small white spot at the base of the cell, a large irregular chestnut-brown, white-edged spot at the cell-end contains sea-green lines surrounding a red-brown spot, on its inside there are 2 oblique green spots bordered with white and strewn darker; postmedian line very fine and indistinct with black and white vein-dots; small white subterminal vein-spots, being larger between 4 and 6, behind them an irregular black line partly edged with white. Hindwing dark brown, costal and inner margins light reddish-yellow. Expanse of wings: 66 mm. Brazil (Rio Purus).

notha. **H. notha** Mschr. (= *rufocinnamomea* Roths.) (157 f). Forewing red-brown with a violet tinge, with 3 broad reddish-yellow brightenings, a more band-shaped one before the middle, 2 spot-shaped ones behind it, brownish orange dusting near the apex and near the anal angle; the wing is traversed by several darker lunular lines, some filled with brownish olive; cell-end spot and apical spot greenish olive. Hindwing greyish-brown. Guiana, Brazil (Amazons).

abscondens. **H. abscondens** Wkr. (157 g) exactly resembles *repandens*, but the forewing is darker reddish-brown, partly shaded with violet, the transverse linear spots are less green, more whitish, coarsely strewn with black, a little more green colour is only in the reniform macula at the cell-end; the other marking is the same. Hindwing lighter yellowish-grey. Brazil.

repandens. **H. repandens** Schs. (= *smerinthoides* Drc.) (157 g). Forewing brown shaded with lilac, the anterior transverse lines grey mixed with greenish, partly bordered with black, grey and greenish-yellow spots strewn black and white are in the cell behind them, a large yellowish-green spot at the cell-end is surrounded with black and white, a smaller one at the apex; postmedian line composed of a row of dark brown, outside yellowish-grey dots, a row of white spots behind it, and an irregular black line, partly strewn white at the distal margin. Hindwing brown, basal half of costal margin yellowish-white. Mexico to Brazil.

apiana. **H. apiana** Schs. is near *repandens*, but separated by the light reddish-brown ground-colour and the 3 very indistinct and partly punctiform transverse lines, and the quite light brownish, almost whitish hindwings; a small grey subcostal spot in the centre of the cell, and a similar somewhat larger one in the lower angle of the cell, the spot in the upper angle being absent; a greyish-green subapical spot. Expanse of wings: 57 mm. Described from Venezuela.

H. gaudens Schs. (157 g) is similar to *apiana*, but larger and more brightly coloured, forewing violet *gaudens*. strewn with white, the anterior transverse lines green and white, the cell-end spot very large, the postmedian line composed of green, black-strewn spots; submarginal white dusting, an irregular undulate black and white line before the margin. Hindwing dark brown. Expanse of wings: 84 mm. Guiana, Colombia.

H. eneana Schs. Thorax reddish cinnamon, forewing light brown, dusted reddish, with a fine irregularly undulated basal line, black, bordered with white inwards; anterior transverse line composed of 3 white and black dots; 3 black rings at the cell-end are filled with black scales, the two exterior ones are connected in the shape of a B; the posterior fine dark transverse line with black and white vein-dots; subterminal line composed of black lunules, with a slightly darker shadow inside before it, and 4 white subapical dots, hindwing lustrous reddish-brown. Expanse of wings: 60 mm. Guatemala (Cayuga).

H. curvilinea Schs. (158 a). Forewing dark red-brown, deepest at the base, inner and distal margins, somewhat lighter reddish-yellow below the base of the cell and between the median nervules; the interior black transverse line is indistinct, the exterior one grey inside, black outside, forming a bow from the costal margin to below the lower median vein, from there another less distinct bow to the inner margin; a large strangulated silvery spot at the cell-end with a golden centre surrounded by red-brown, a smaller one above it and before it; postmedian area dusted lilac and shaded grey; black dots before the margin, and a large silvery spot at the apex. Hindwing dark grey. Guiana.

H. simplex Wkr. (= *hapygia* Fldr., *ribbei* Schs. nec Drc.) (158 a). Forewing dull dark red-brown, spotted dull orange basally below the cell and at the inner margin, with fine black transverse lines, the anterior one indistinct, the posterior one almost straight, slightly bent, strewn with whitish-grey inside, somewhat more thickly on the veins; with or without a strangulated silvery spot at the cell-end, marked red-brown inside, a small one above it; the indistinct subterminal line is only marked by faint lighter red-brown dusting on its outside; a very irregular submarginal black and grey line more broken up into dots, a small narrow silvery spot at the apex. Hindwing greyish brown. Mexico, Central America.

H. beuvea Schs. is allied to *simplex*, but the forewing is unicoloured cinnamon, the postmedian line is nearer at the cell, and the white dots in the distal third of the costal margin are absent; reniform macula loam-coloured, narrow, edged by fine black lines, another small spot above inside, from the inner side of the reniform macula a darker shadow extends to the inner margin at the posterior transverse line; the latter extends straightly to the anal angle, light reddish-grey, bordered darker outside; an indistinct irregular shadow before the fine undulate subterminal line. Hindwing reddish-brown. Expanse of wings: 72 mm. Amazons (Intaly).

H. raatzi Mschlr. (158 a) is extremely similar to *simplex* and probably only the southern form of it; forewing of the same colouring, the silvery spots somewhat larger, but they may also be absent in both the forms. Characterized by the postmedian line invariably forming an inward angle below the lower median vein. Guiana, Brazil.

H. ribbei Drc. (158 a) is another species very similar to the two preceding ones; forewing somewhat brighter red-brown, fine yellow vein-dots on the inside of the postmedian line, the cell-end spot and the apical spot are more golden, the submarginal black dots extremely fine. Hindwing lighter brownish-grey. Panama.

H. millsii Schs. Forewing fawn-coloured, suffused with reddish violet, obliquely cut off by reddish cinnamon in the basal area, forming 2 distal bows, with a black basal line in it; the vertical anterior transverse line is almost in the centre; reniform spot reddish ochreous with a smaller spot inside above it, and an oblique shadow before it to the inner margin; the straight dark postmedian line, with a white dot on vein 1, bordered inwards by lighter reddish-brown; marginal area broad reddish-yellow cinnamon. 4 white dots at the costal margin; the irregular subterminal line is black, between 7 and 8 as a fine white line. Hindwing reddish-brown, with a pink tinge at the margin. Expanse of wings: 75 mm. Peru (Carabaya).

H. directa Schs. is the smaller insular representative of the preceding species, from Cuba. Forewing reddish-brown, the anterior transverse lines very indistinct, grey, undulate, the posterior one grey, bordered with black outside, in an oblique line from the costal margin to the lower median vein, from there undulated to the inner margin; silvery spots as in *raatzi*; a subterminal row of small black spots. Hindwing duller reddish-brown, with yellowish hair at the inner margin. The silvery spots may be absent as in all the other species.

H. rufescens Schs. (158 b) is a still smaller species with red-brown forewings, the anterior transverse line replaced by small grey vein-spots, the exterior one is feebly curved and dark red-brown; an undulate dark brown shadow before the blackish subterminal double dots, the apical ones of which are confluent and dusted with white; a silvery crescent at the cell-end, a small round spot above it. Hindwing blackish-brown, reddish-yellow at the costal margin. Expanse of wings: 48 mm. Venezuela.

plateada. **H. plateada** Schs. Forewing of a bright brown colour, costal margin blackish, the anterior transverse lines fine black, the antemedian line oblique to the centre of the inner margin, 2 black spots before it above the inner margin, another spot below the lower median vein, and one behind the cell, an uncommonly large triangular silvery spot in the cell-end, its shape resembling that of the genus *Chliara*; the anterior inner part is divided by a fine line, the other part is marked red-brown; an irregular large silvery spot is before the black apex, indistinct black subterminal spots below it. Hindwing yellowish-white. British Guiana.

dorema. **H. dorema** Schs. Forewing dull yellow, the anterior transverse line is divided into 3 reddish-brown small spots, the largest of which is above the inner margin; a fine reddish line from the centre of the cell to the inner margin, a dark spot is here before it, the fine straight postmedian line is finely edged with white inside and crosses a broad reddish shadow, grey shading is also behind it; silvery spots in the cell-end as in *plateada*; apex dusted grey and white with a silvery crescent before it, above and below which there is one silvery drop each besides; subterminal dots and streaks in the red-strewn marginal area. Hindwing white. Expanse of wings: 63 mm. Described from Guatemala.

149. Genus: **Rhapigia** Schs.

A few species with special wing-contours, hitherto ranged under *Hapigia*, have been recently separated from them as *Rhapigia*. They are distinguished by the remarkably high shape of the forewing with a deeply cut out inner margin and lobately produced anal angle.

Type of genus: *Rh. accipiter* Schs.

accipiter. **Rh. accipiter** Schs. (158 e) has very strikingly shaped wings, the feebly bent distal margin being almost just as long as the costal margin and terminating at the anal angle in a long dent, for which reason the inner margin is very short. Forewing dull red-brown, brighter in the basal half, an orange spot in the basal half of the inner margin; transverse lines indistinctly lighter, bordered with dark, the anterior one terminating in 3 bows into the dent, the posterior one almost straight; a dark dot in the cell, 2 lighter small spots at the end; a fine black undulate line in the somewhat lighter marginal area, more distinctly W-shaped before the apex, and bordered with white inside. Hindwing blackish-brown, dingy white along the costal margin. Brazil.

aymara. **Rh. aymara** Schs. (158 e) has somewhat similarly shaped wings, also with an anal-angular dent; forewing lilac brown, darker in the basal half of the costal margin, with lighter transverse lines, the anterior ones with lunar spots, the posterior ones almost straight, with short black vein-streaks before them and dots behind them, a large blackish spot near the anal angle; 2 silvery spots at the cell-end are finely bordered with black, and a narrower spot is at the apex, from which the irregular black marginal line proceeds. Hindwing smoky grey, whitish basally. Colombia, Guiana.

deicola. **Rh. deicola** Schs. Anterior body cinnamon-brown, tegulae apricot-coloured, abdomen brown above, reddish-white beneath. Forewing brown as far as the reddish-yellow marginal area, dusted with brown from the apex to vein 3; the subbasal and anterior transverse lines consist of reddish cinnamon, partly connected spots, parted by dark lunules; a similar oval spot at the cross-vein with a smaller one inside above it; postmedian line undulate, bordered with grey inside, with vein-dots; subterminal line black, deeply undulated, bordered with white towards the apex. Hindwing sand-coloured brownish with a whitish basal costal-marginal

agnesa. part. — f. **agnesa** Schs. exhibits a black spot at the inner-marginal excision and another postmedian one on vein 4. Expanse of wings: 45 mm. Brazil (Rio Purus).

klagesi. **Rh. klagesi** Rothsch. Forewing purple brown, partly shaded chestnut-brown and dusted pinkish violet, shaded sooty black postdiscally and in the centre of the inner margin; the curved blackish postmedian line is indistinct and has grey vein-dots, the submarginal line is notched as in *deicola*. Hindwing reddish-grey. Amazons (Fonte Boa).

rotundata. **Rh. rotundata** Dogn. is allied to *klagesi* and similarly marked, but the wings are differently shaped, the distal margin and the anal angle of the hindwing uniformly rounded, forewing chestnut brown, with yellowish spots in the distal half of the cell, submedianly and subterminally; the black margins are very fine and inconspicuous, accompanied by whitish scales, the anterior lines only composed of vein-dots, 2 small streaks at the cell-end. Hindwing light brown, yellowish basally. Expanse of wings: 47 mm. Amazons.

150. Genus: **Chliara** Wkr.

Separated from the preceding ones by the antennae not being nodularly thickened basally; vein 6 of forewing not stalked with the subcostal branches, but rising separately from the upper cell-angle. Only few tropical species are known, some of which abound remarkably in silver and gold decorations.

Type of genus: *C. croesus* Cr.

C. croesus Cr. (= *croesa* Hbn., *imperialis* Wkr.) (158 b). Forewing light reddish-yellow, of a deep purple brown at the inner margin and apex, with two similar oblique antemedian stripes; numerous large and small silvery spots are basal, around the cell-end, and at the apex; the dentate double transverse lines and the subterminal line are filled or edged with a silver or gold colour. Hindwing light reddish-yellow, more brownish in the female. Brazil. *croesus*.

C. moneta Fldr. is very similar, with somewhat narrower wings, more intensely dusted with purple red, especially in the median area at the costal margin, the silvery spots somewhat reduced, particularly at the base and apex, especially in the basal area. It may be only the northern representative of *croesus*. Panama. *moneta*.

C. mediostriga Roths. (158 b). Forewing reddish orange with numerous cinnamon red antemedian and postmedian lunular lines, the centre itself purple reddish-brown with two reddish-yellow spots at the cell-end; the double subterminal line is black just as a longitudinal stripe from the base along the median vein and the upper median nervule. Hindwing light reddish-brown. Guiana, Amazons. *mediostriga*.

C. gaedei n. sp. (158 b) resembles *mediostriga*, but it is much larger and with longer wings. Forewing reddish fawn, with a large whitish subapical spot, the lower end of the reniform macula also filled with whitish; with the same black longitudinal stripe and a black subbasal line composed of two reverse bows; anterior transverse line marked by black vein-dots and a shadow-like feeble grey lunular line; a very small pear-shaped ring in the cell, another ring outside above it, the reniform macula is formed by an oval ring-line with a distal indentation on vein 5; postmedian line oblique, shadow-like, only the two bows between 2 and 4 more distinct, with a few vein-dots behind it. A fine black submarginal serpentine line. Hindwing light reddish-brown, somewhat transparent in the disc. Type: 1 ♂ from Chuchuras, Peru, in the Berlin Museum, another ♂ from Colombia. ♂ antennae hardly dentate, finely ciliated. On examining this species closely it is found to belong rather to *Hapigia*. *gaedei*.

C. rovena Schs. is still more similar to *mediostriga* and much smaller. ♂ antennae serrate with long ciliary tufts. Forewing light reddish-brown with the black longitudinal line of the preceding species, the origins of veins 2 and 3 being also black; a black spot in the centre of the cell, the black reniform macula line is open above, the median area below the median vein darker, brownish, and lighter, more reddish, above it; traces of a double postmedian line, with black scales before and behind it between 5 and 6; subterminal line between the costal margin and 5 only composed of a few black scales, undulate dentate below; small black spots above and below vein 4. Hindwing slightly transparent, light reddish, the veins, the inner margin broadly, the distal margin narrowly reddish ochreous. Expanse of wings: 42 mm. Sa. Catharina. *rovena*.

C. svidberti Schs. differs in the pectinate antennae of the ♂. Forewing reddish-yellow with a violet tint, the median area slightly darker, though not so much as in *rovena*; transverse lines extending as in *mediostriga*, very indistinct before the centre, the outermost line bordering on the median area inside, with black vein-dots; a small white spot at the cell-end, black and white vein-dots behind it; the posterior transverse line is double, scarcely darker than the ground. Hindwing reddish, darker at the inner margin. Expanse of wings: 43 mm. Guatemala. *svidberti*.

C. novicia Schs. shows tuftedly ciliated antennae in the ♂. Forewing reddish-brown, dusted with lilac, and striated darker below the cell; the anterior transverse lines are broken up into single vein-dots, the posterior one is double in the ♂, single in the ♀, with black vein-dots behind it; two small black-edged ring-spots in the cell, a cross-shaped spot at the cell-end is blackened at its distal end in the ♀; the fine irregular black marginal line ends in a black apical spot in the ♂, in a shadow in the ♀. Hindwing light reddish-brown. Expanse of wings: ♂ 42, ♀ 56 mm. French Guiana. *novicia*.

151. Genus: **Antaea** Hbn.

Separated from *Chliara* by a longer terminal joint of the palpus and the slightly notched distal margin of the forewing. Neuration the same except the costal vein of the hindwing branching off here from the centre of the cell, while it extends more parallel and does not bend down so much in *Chliara*. Only 3 species are known.

Type of genus: *A. juturna* Cr.

A. juturna Cr. (158 c). Forewing red-brown with 6 dark transverse lines, all of which are faded distally, distinctly defined inwardly and edged with light here, so that they look somewhat embossed: the second extends only to the median vein, the fourth is scalariformly interrupted on the upper median branch and removed inwardly as far as the lower cell-angle, the fifth extends more obliquely than the others, and the submarginal one is scalariformly interrupted on the two median nervules; a reniform macula at the cell-end shows a somewhat darker filling and meets outside a short oblique line. Hindwing dark greyish-brown. Panama to Brazil. *juturna*.

licormas. **A. licormas** Cr. (= *bombycoides* Wkr.) (158 c) is marked in almost the same way, but the ground-colour is a lighter violettish grey, strewn somewhat darker brownish in the lower half of the marginal area; transverse lines finer, the macula before the cell-end is not confluent with the 4th transverse line, subterminally there are small blackish shadowy spots, and the submarginal line has 3 scalariform interruptions partly of an orange colour. Hindwing lighter brownish-grey. Mexico, Panama.

omana. **H. omana** Schs. (= *pseudosmerinthus* Rothsch.) (158 c) is very similar to *licormas* and may be only a larger southern form of it; the ground-colour is quite similar, the best mark of distinction is the postmedian line which is not straight but curved, the reniform macula at the cell-end is open below and its distal arm is strewn with orange, and so are the 3 scalariform interruptions of the submarginal line; the distal margin is more notched, the hindwing shows a darker greyish-brown colour. Expanse of wings: 71 mm. Colombia, Brazil.

152. Genus: **Pseudhapigia** Schs.

Easily separable from the preceding species by the antennae of the ♂ being pectinated to the tips: last palpal joint very short. Distal margin of forewing rounded, inner margin cut out with a dentiform projection near the anal angle; as in *Hapigia*, the uppermost radial branch is stalked with the 4 lowest subcostal branches. Hindwing: the upper median branch and the lowest radial branch are somewhat separated at their origins, the rest of the neurulation as in *Antaea*. 3 species are known.

Type of genus: *P. brunnea* Schs.

brunnea. **P. brunnea** Schs. (= *estrella* Barnes) (158 c). Forewing light red-brown, monotone, with fine blackish transverse lines, the anterior ones undulating, the posterior one slightly bent, forming an angle submedianly and extending into the anal angle behind the dent; a roundish silvery spot in the cell, behind it at the end there is a larger lobate silvery spot; 2 small narrow silvery spots are at the apex before the irregular subterminal line, the apex behind them being blackened. Hindwing light brownish-grey. Arizona, Mexico. — *colimae* f.n. (158 d) is much darker, profusely dusted with purple and shaded with blackish, the latter especially behind and below the cell, where it is spotted orange basally; the postmedian line is broadly bordered with light violettish-grey inside, the silvery spots are centred red-brown. Colima.

kurunensis. **P. kurunensis** Dogn. has chestnut-brown forewings, with very fine and rather indistinct violet dentate antemedian and postmedian transverse lines, accompanied by fine black and white vein-dots; a black dot in the cell and, above it, a subcostal row of dots; the subterminal internerval dots are bordered with white apically. Hindwing light brown. French Guiana.

misericordia. **P. misericordia** Dyar (158 d). Forewing dark brown, strewn black, some places, especially near the undulate line, are somewhat lighter; anterior transverse line indistinct, the posterior one straight, slightly bent only on the inner-marginal vein; undulate line indistinct, dentate, more distinctly prominent in the centre as a dark double line, 2 subapical bows bordered with white; two small silvery spots centred with red-brown are in the cell, or also without silver. Hindwing dark brown. Mexico.

153. Genus: **Hapigiodes** Dyar.

Very closely allied to the preceding genus, chiefly separated by the antennae of the ♂ being pectinated only on two thirds; besides, the origins of the upper median branch and of the lowest radial branch are more separated; discernible from the very similarly structured genus *Colax* by the inner-marginal dent.

Type of genus: *H. xolotl* Schs.

xolotl. **H. xolotl** Schs. (158 d). Forewing dull brownish-grey, the interior undulate line very indistinct, the exterior one straight, its lower third bent towards the anal angle, brown, bordered with reddish-yellow inside, the submarginal line irregularly angled, subapically bordered with silver; the cell-end with the usual 2 silvery spots with a golden gloss, the larger lower one marked red-brown inside. Hindwing brownish-grey, yellowish-white basally. Mexico.

argentidiscata. **H. argentidiscata** Schs. may be a southern race of *xolotl*, but it is lighter, and the postmedian line is more remote from the apex. The proximal lower half of the forewing, obliquely from the costal margin to the anal angle is wood-coloured brown, reddish-yellow above it; instead of the anterior transverse line there are black dots and lunules with 2 small black spots before them; an oblique large golden and silvery spot at the cross-vein, a smaller one above before it; the brown postmedian line is bordered with whitish inwards, behind it there are patches of brown dusting, and black scales on vein 4; subterminal black lunules, and a black line bordered with silver between 7 and 8. Hindwing reddish and brown. Expanse of wings: 51 mm. Sa. Catharina (Taragua).

proxima. **H. proxima** sp. n. (158 d) is very closely allied to *xolotl*, but of a light brown colour, shaded with blackish behind the postmedian line, so that a notched shadowy band contrasts with the lighter marginal area here,

both the undulate anterior transverse lines very indistinct, the posterior one straight to the submedian fold, where it is slightly flawed and extends towards the anal angle, forming another obtuse angle distally on the inner-marginal vein; the blackish submarginal line is hardly traceable. Hindwing light greyish-brown. Described from a female with pectinated antennae, from Misantla (May 1912). Type in the Coll. DRAUDT.

H. arpi *sp. n.* (158 e) is smaller than the preceding species, dull greyish-brown, especially towards the *arpi*. inner margin, shaded with blackish, most intensely so in the median area, the transverse lines similar to those in the preceding species, the anterior one distinct, composed of arcuate lines which form tiny black inward dents on the veins, the posterior one straight to the submedian fold above which it forms an almost right angle with its point inwardly, whereupon it forms another outward flaw on the inner-marginal vein; subterminal shadow distinctly notched owing to the marginal brightening behind it and forming a large black spot near the lowest radial branch; submarginal line distinct bordered with single silvery scales inside, with chalky white on both sides towards the apex; silver spots large with a golden shine, the lower shaped like an 8, enclosing 2 red-brown circles. Hindwing blackish brownish-grey, lighter in the ♀, more yellowish-white. South Brazil (Sa. Cruz, Joinville). Types: ♀ ♂ in the Senckenberg Museum.

H. frederica *Dyar* (158 e) has rusty brown forewings shaded with violet behind the base of the costal *frederica*. margin obliquely to the anal dent; the blackish transverse lines are bordered with light on the averted sides, the interior one arcuate, the exterior one straight, bent on the inner-marginal vein; two dark brown oblique maculae at the cell-end, the black fine submarginal line is bordered with silver inside at the apex. Forewing dingy whitish. Shape of wings somewhat different, the distal margin of the forewing forming a projection on the middle and upper radial branches, below it is straight or almost concave, the inner-marginal dent very large, similar to that of *accipiter*. Mexico (Cordoba).

H. nigridiscata *Dogn.* resembles *frederica* by the same shape of the wings and the same markings, but *nigridis-* on the hindwing the two branches of the lower cell-angle arise from one and the same place. Forewing brown- *-cata* ish-grey, the markings blackish, the two cell-end spots also black. Hindwing all white. Expanse of wings: 46 mm. Argentina.

154. Genus: **Canodia** *Guen.*

Like *Pseudhapigia*, but the longer forewing with a pointed apex, a rounded oblique distal margin and a straight, not cut out proximal margin.

Type of genus: *C. carmelitoides* *Guen.*

C. carmelitoides *Guen.* The figure of this species which seems not to have been rediscovered is very *carmelitoides*. similar to the following species; a female lying before me, in my opinion, belongs to it; forewing light reddish-brown, somewhat more yellow basally, with 2 double undulate antemedian transverse lines, the inverted parts less distinct and lighter, the averted parts dark red-brown, the outer line forms a distinct bow distally on the submedian fold; an oval of a brighter red-brown filling, surrounded by purple brown, contains a somewhat undulate dark central streak; the oblique postmedian line is dark brown, with a narrow lighter distal border, and it forms a distal angle on the inner-marginal vein and a flat inward bow above it; below the last quarter of the costal margin it turns distally and extends into the apex; the costal margin is purple brown, particularly apicad, and strewn with lilac white downwards, the undulate golden yellow subterminal area is very much expanded towards the anal angle, and behind it there are very fine black internerval dots in the brown ground of the margin. Hindwing reddish-brown, light yellow at the costal margin, fringe reddish golden yellow. Under surface light reddish-yellow, the disc of the forewing somewhat brownish. Brazil.

C. difformis *Herr.-Schäff.* (= *pogoda* *Dogn.*) (157 d) is very similar to the preceding species, but the *difformis*. forewing is more brownish olive with a pinkish tint, the two anterior transverse lines are not double, the space between them is darkened; the subterminal area is not yellow, but only of a somewhat lighter ground-colour, the hindwing is greyer. Forewing beneath grey, with a pinkish tint towards the margin, the ends of the veins and the fringe yellowish pink. From Venezuela and Colombia.

Subfamily: **Melalophidae.**

A subordinate group of the large Notodontid tribe, separable only biologically, with hairy larvae; owing to the absence of clearly defined marks of distinction, it cannot be regarded as a distinct family. The larvae exhibit tubercles with secondary hairing, and by the characteristic three tubercles above the stigmatal tubercle on the thoracal segments they are separated from the parallel formation of the Arctiid larvae. The imago has a rudimentary proboscis, whereby they also approach the *Eupterotidae* which, however, have only 11 veins on the forewing, whilst the *Melalophidae* and the *Notodontidae* exhibit 12. As next to nothing is known of the biology of the majority of the tropical *Notodontidae*, we cannot tell of course whether one or the other from the preceding genera may be better ranged here.

The subfamily is subdivided into 2 rather heterogeneous parts: the „moonbird“-like species of *Datana* and *Ichthyura* (Pygaera), and the green *Rosema* with quite dissimilar imagines, while their larvae — as far as they are known — are green with short hair, their structure and behaviour being otherwise very much like that of the *Ichthyura*-larvae.

155. Genus: **Datana** Wkr.

♂ antennae not pectinated, only ciliated; palpi short and obtuse, appressed to the frons, the 2nd joint covered with long tufty scales; the broad thorax is densely haired. Neuration exactly like that of the genus *Nadata*. Femora and tibiae with dense shaggy hair. The larvae exhibit the same shape and colouring as those of the *Phalera*, being black or brown with numerous yellow longitudinal stripes; their behaviour is also the same, the head and anal end being raised when in repose. Quite a number of very similarly looking and therefore not easily discernible species; mostly from North America.

Type of genus: *D. ministra* Drury.

- angusii*. **D. angusii** Grt. & Rob. (158 f) is distinguishable by the colour of the forewings being quite smoke-brown or blackish-brown. Here and in the 3 next species, the distal margin is somewhat undulate-dentate. The marking is otherwise exactly the same as in *ministra*. Similarly dark brown colour is only exhibited by *integerima*, but the distal margin of its forewing is even, not undulate-dentate, and the hindwing is much lighter; besides, *angusii* has less strewn wings, and the transverse lines are not bordered with a lighter colour. The larva is black, with 4 whitish-yellow longitudinal lines on each side, and red abdominal legs and red bases of the thoracic legs; the scanty side-hairing is whitish-grey. It lives on species of nuts (hickory and walnut), but also on birches and lime-trees in July and August, the imago in April till July. Canada to Illinois.
- ministra*. **D. ministra** Wkr. (158 f). Forewing reddish cinnamon, mesothorax ochreous in front, warming into chestnut brown behind, hindwing light straw-coloured. Lighter than *angusii*, but darker than *californica*, smaller than *drexelii* and *major*, with less distinct, or absent, small discal spots, without the dark costal-marginal shadow of *drexelii*, the hindwings mostly lighter than in *major*. Larva black with 4 broad, more greenish-yellow longitudinal lines on each side, the ventral legs and the bases of the thoracic legs being reddish-yellow; hair longer and white. It lives gregariously on nearly all the deciduous trees and pupates in the earth without a cocoon. Canada to California.
- californica*. **D. californica** Riley is almost the same, but much lighter, more pale straw-coloured with a very faint reddish tint. Larva on apple and plum, very similar to that of *angusii*, but with 5 more lemon-coloured longitudinal lines on each side, abdominal legs greenish-yellow.
- drexelii*. **D. drexelii** Edw. (158 f) is larger than *ministra*, the margin somewhat less distinctly undulate-dentate, marked like *ministra*, but with a very distinctly contrasting, darkened costal-marginal area; the colour is brownish ochre, the thoracal spot darker than in *ministra*, the discal spot large and distinct, darker than the lines. Hindwing darker than in *ministra*. Larva very much like the preceding ones, black with lemon-coloured longitudinal lines, the neck-shield and the first half of the first segment quite honey-coloured, also the last abdominal segment almost quite yellow, the abdominal legs and the bases of the thoracic legs being yellow, too. It lives on Hamamelis and Vacciniae, also on lime-trees and Sassafras. New York, New Jersey.
- major*. **D. major** Grt. & Rob. (158 f). The species following now exhibit an entire, smooth margin of the forewing. A large species with yellowish tan-coloured wings, somewhat darker than in *ministra*, with darker hindwings than in *drexelii*, discal spot large and distinct as in *drexelii*, but without its contrasting costal-marginal shadow. Larva black with very broad, frequently interrupted yellowish-white or dark yellow longitudinal stripes; head, abdominal legs and the bases of the thoracic legs from orange brown to mahogany-red. It lives on *Andromeda ligustrina* and *mariana*. Atlantic States.
- floridana*. **D. floridana** Graef (158 f) is smaller than *major*. Forewing dark brown with a slight purple tint, the lines therefore not very distinct, but with a prominent discal spot. Larva somewhat duller black, head and abdominal legs mahogany-red, the lines yellow. It lives on *Andromeda mariana*. Florida.
- palmii*. **D. palmii** Beut. (158 g) is like the preceding, but lighter, the lilac whitish ground of the forewing densely strewn with brown, with a browner costal-marginal shadow, only the lines 1, 2 and 5 distinct, the two others feeble, discal spot more extinct; it may not differ specifically from *floridana*. Larva like that of *floridana*, but the head is more orange red, the lines are lighter yellow; on *Vaccinium stamineum*. Atlantic States.
- modesta*. **D. modesta** Beut. has a traceably undulate-dentate distal margin of the dark hazelnut-brown forewing without a darker costal-marginal shadow, with quite indistinct lines, but a distinct blackish discal spot; remarkable for the yellowish ochreous thoracal spot which is lighter than the rest of the thorax. Larva apparently still unknown. Expanse of wings: 51 mm. Florida.
- perspicua*. **D. perspicua** Grt. & Rob. (158 g). Thorax and forewing reddish-yellow, thoracal spot ochreous, warming into tan-colour behind; forewing scantily strewn with brown except the costal-marginal area; the lines and

the large discal spot hazelnut-brown, the apical oblique streak especially long and distinct, the median nervules also brown. Hindwing very light reddish-yellow. Larva from reddish to blackish-red, the lines lemon-coloured, head black like the legs. It lives on Sumach (various species of *Rhus*). New York to the Gulf States and Kansas. — **robusta** *Stkr.* (= *mesillae* *Cockll.*) differs in the not darker, plainly ochreous thoracal spot, the forewing being of a somewhat more loamy yellow tint, the lines less distinct. Texas and New Mexico. — **opposita** *B. & Benj.* has a lighter, more ochreous thorax, the forewing is lighter than in the type, hardly strewn, the lines are less distinct, the discal spot is more obsolete. From Utah. — **discahis** *Dyar* is more profusely and uniformly strewn with brown, the reniform macula is a thick brown spot, the subapical streak is broad and faded; the basal part of the wing as far as the first line is dusted somewhat violettish-grey, the exterior line is especially distinct. The larva shows a more black than red ground-colour. California. — ab. **infusa** *Dyar* belongs to the latter form, but it is still much more densely strewn with brown, so that it appears to be quite brown; the lines are bordered with a somewhat lighter colour, but the subapical streak is absent. San Diego (California). — **eileena** *Dyar* resembles *discahis*, but it shows a softer tinge, dusted rather than strewn with brown, discal spot smaller, the lines distinct, but very fine, apical streak absent. From Arizona. — ab. **perfusa** *Dyar* is a form of it, parallel to ab. *infusa*, but not so densely brown, lines almost extinct, without the discal spot. From South Arizona.

D. diffidens *Dyar*. Head yellowish, thoracal spot brown, silvery grey hindward. Forewing uniformly brown, somewhat loamy yellowish at the costal margin, densely strewn silvery grey, interior and exterior lines fine, brown, the middle lines more obsolete, discal spot dark brown, strewn with silvery grey; the subapical oblique streak between 7 and 4 very distinct. Hindwing light yellowish-white, brown towards the margin and strewn with silvery grey. Expanse of wings: 46 mm. Texas (Victoria). Larva not described; it is said to do harm to oaks.

D. contracta *Wkr.* (158 g) has a quite smooth margin; thoracal spot ochreous, tan-coloured behind, the rest of the thorax lighter than the reddish-yellow forewings, the costal-marginal shadow more ochreous; forewing strewn with blackish-brown, the similarly coloured lines are bordered with unstrewn ground-colour. Hindwing lighter, somewhat glossy, strewn with brown towards the margin. Larva black with very broad yellow lines, so that the ground-colour appears to be yellow, head black, bases of thoracic legs and abdominal legs yellow. It lives on oak, hazel, and hickory. Atlantic States.

D. integerrima *Grt. & Rob.* (158 g) is like *contracta*, but of a dark reddish-brown ground-colour, more densely strewn, lines and fringe of the same colour, whereas in *contracta* they are lighter brown than the blackish-brown lines; discal spot blackish. Larva blackish-brown, with but two greyish-white lines on each side, densely grey-haired; on many deciduous trees, but chiefly on species of nut. Atlantic States.

D. neomexicana *Doll.* is allied to *integerrima*, but the forewing is almost unicoloured pale grey, scantily strewn dark, the costal-marginal shadow not contrasting much, pale ochreous; discal spot obsolete, the lines as usual, the oblique apical blotch also faded. It resembles also *californica* in the shape of the wings. New Mexico.

D. chiriquensis *Dyar* (159 a). Forewing very light reddish-yellow, brownish ochreous in the costal-marginal area, strewn with brown, often somewhat darkened between the two first lines; the lines 1, 2 and 5 thickly red-brown, 3 and 4 less distinct, somewhat undulate, bordered somewhat lighter distally, another fine line is often traceable between 2 and 3; discal spot strigiform, blackish, fringe red-brown. Hindwing somewhat lighter, with a red-brown tinge towards the margin. Thorax almost silvery white laterally, the central spot rusty red. Arizona, Mexico.

D. holoporphyræ *Dyar* is violettish-grey, strewn with brown, the broad marginal area somewhat lighter, dusted bluish outside, the apical oblique line extends to vein 4, the purple brown lines are indistinct, the space between them darkened, the outermost line slightly excurved between 2 and 6. Hindwing densely strewn dark purple brown. Expanse of wings: 49 mm. Mexico (Guerrero Mill), in the State of Hidalgo.

D. rotundata *sp. n.* (159 a) resembles *chiriquensis*, but it is somewhat smaller and discernible by the darker, more violettish-grey colour, only the costal-marginal area being somewhat more ochreous; lines brownish-black, of a much more rounded course than in *chiriquensis*, not bordered with a lighter colour, 1, 2 and 5 most distinct, 4 almost quite invisible, the area between them not darkened; apical streak fine and distinct, the margin below it darker violettish grey. Hindwing light brownish cinnamon, much darker than in *chiriquensis*. Thorax silvery white, the spot tan-coloured like the abdomen. Mexico (Colima). Type in the Coll. DRAUDT.

156. Genus: **Ichthyura** *Hbn.*

Smaller insects with hairy eyes and pectinate antennae, with large, long palpi, appressed to the frons. Thorax with a conical central tuft. Wings short and broad, forewing without an areole, the subcostal branches bent much towards the costal margin, 3 and 4 separated, 6 stalked with the subcostal branches. Hindwing: veins 6 and 7 stalked. Numerous North and Central American species. The name: *Melalopha* *Hbn.* Tent. is declined as generic name, it was only used as a name for the species comprised here in a group: *Melalophae*.

Type of genus: *I. curtula* *L.* (palearctic).

- apicalis*. **I. apicalis** Wkr. (= *vau* Fitch., *indentata* Pack.) (159 a). A small, most variable species, somewhat like the palaearctic *pigra*. Body and forewing dark ash-grey, with a short straight subbasal line and an oblique anterior transverse line which meets the posterior one on vein 1, the latter line terminating at the costal margin with a small white spot which is generally bordered with rusty brown outside; apical third darkened still more; a subterminal row of small dark spots. Hindwing mouse-coloured, often with an indistinct postmedian transverse line. — **ornata** Grt. & Rob. (= *incarcerata* Bsd.) is a slightly larger and paler form of the Eastern States.
- astoriae*. — **astoriae** Hy. Edw. is still larger and lighter, and it lacks the rusty brown spot at the costal margin altogether. Nebraska, Oregon, Montana. — **bifiria** Hy. Edw. is a very large contrasting form from California; the anterior transverse line is quite straight. Larva yellowish-brown, with a grey tinge and grey hair; the 4th and 11th segments are often darker and more reddish, with yellowish tubercles bearing bristles. It lives on trembling-poplar and willow, and pupates between leaves. Widely distributed throughout North America, from Alaska to California and to the Pacific Coast.
- paraphora*. **I. paraphora** Dyar is a large light grey species, marked like *apicalis*, but the lines are more undulated and somewhat differently situate, the oblique line strongly bent between the exterior and interior lines; ground-colour light grey, clouded darker grey, especially in the basal area, in the "V" below vein 2; very little rusty brown at the costal margin. Expanse of wings: 31—38 mm. Arizona, Colorado.
- inornata*. **I. inornata** Neum. (159 b) is much larger than *apicalis*, the largest and lightest of all the species, marked almost exactly like the form *ornata* of *apicalis*, of a somewhat more yellowish tint, probably only a southernmore race. South Arizona, Mexico. Larva unknown.
- inclusa*. **I. inclusa** Hbn. (= *americana* Harr.). Light ash-grey with yellowish ochreous tints and dusted with brown, the lines similar as in the allies, but whiter, very straight and bordered with brown outside and forming a pointed "V"; a subterminal row of small brown spots. Hindwing with an undulated postmedian line. Atlantic States. Larva yellow with a more or less greenish tint, with 3 black dorsal longitudinal lines and 3 lateral ones on each side, the 4th and 11th segments with blackish prominences bearing bristly warts. It lives between leaves of poplars and willows, which have been spun together. — **inversa** Pack. (= *palla* French)
- inversa*. is smaller and darker, greyer, the subterminal row of spots less distinct. Canada, Nebraska, Colorado. — **jocosa** Hy. Edw. is a small form, of a more yellowish ochreous tint, the hindwing without a postmedian line. Florida.
- strigosa*. **I. strigosa** Grt. is smaller and duller brown than *apicalis* with a faint lilac tinge; the subbasal line is distinct and it forms a sharp angle on vein 1, the second line is much more incurved; separated from all the other species by a large irregular whitish ochreous spot adjacent to the outer line at the costal margin and extending half-way to the apex. Hindwing darker than in *apicalis*. Larva yellowish with 3 indistinct red dorsal stripes and 3 deep red lateral stripes; abdominal legs flesh-coloured, head dull black; on *Populus tremuloides*.
- luculenta*. Northern Atlantic States. — **luculenta** Hy. Edw. is an insignificant form lacking the dark brown stripe on the mesothorax; the light costal spot is more distinct and somewhat more obliquely situate.
- brucei*. **I. brucei** Hy. Edw. (159 a) has a whiter ground-colour with bright brown markings; a whitish subbasal line bordered with brown, somewhat dentate in the middle, and a straight antemedian line; a postmedian brown shadow through which the purely white postmedian line extends, widened at the costal margin; a subterminal row of brown spots, the middle spot in a brown shadow. Hindwing mouse-coloured. — **multnoma** Dyar (= *alethe* Neum. & Dyar) is a darker form. The larva is purple black with a broad yellow dorsal band containing 3 fine black interrupted dorsal lines; the yellow colour turns more bluish-grey in the course of growth; tubercles partly orange; the prominences on the 4th and 12th segments are deep black, a broad lateral orange band is more or less interrupted by black. It lives on willows. Oregon; Washington; British Columbia.
- albosigma*. **I. albosigma** Fitch (159 a) is somewhat larger, less yellowish than *inclusa*, with a slight lilac tinge, distinguished by a large dark apical spot bordered inside by the acutely angled postmedian line which forms a distinct white spot at the costal margin; all the 3 whitish lines are rather parallel. Hindwing very light, without a transverse line. — **specifica** Dyar is a much lighter form from Colorado. The larva is straw-coloured with 3 grey or light reddish-brown dorsal lines and a broad lateral stripe, all more or less interrupted. It lives on poplars and willows. Northern United States.

157. Genus: **Rosema** Wkr.

A group of green *Notodontidae* of a very homogeneous exterior, but of varied shapes. I combine the genus *Moresa* Wkr. with *Rosema* Wkr., because I cannot discover any essential anatomical difference. They are small to medium-sized insects with very differently shaped wings; apex of forewing generally rather pointed, the distal margin often concave, often with a projection between veins 5 and 6, so that two concavities are

produced; the costal margin of other species exhibits a nodiform prominence between the middle and distal thirds. Head small, with large ball-shaped eyes; proboscis rudimentary, palpi not projecting beyond the frons, with appressed scales. Antennae with double pectinations, also the ♀♀ generally with short pectinations. Forewing: veins 3 and 4 arise separately, the cross-vein is very acutely angled, vein 5 from the upper cell-angle or close below it, 6 from the centre or towards the end of the very narrow long areole, from the end of which 7—9 and 10 arise. Hindwing: 5 from the centre of the cross-vein, 6 with 7 on a fairly long stalk. As far as they are known, the larvae exhibit the same shape and habits as those of the *Ichthyura*, but they are green and short-haired.

Type of genus: *R. dorsalis* Wkr.

R. zelica Stoll (159 b) is an apparently very rare form with an entirely green thorax; a much more *zelica*. common form is: — **dorsalis** Wkr. (159 b) with a dark brown collar and middle longitudinal stripe on the thorax. *dorsalis*. Wings of a deep green with a very fine white discal dot, a fine white costal margin and 2 or 3 small dark brown fringe-spots at the slightly falcate apex. Hindwing white, more or less tinged yellowish, more yellowish at the inner margin. Abdomen light reddish-brown, green at the end and beneath. Characterized by the under surface being light green with a broad reddish-yellow costal margin and a narrow brownish marginal spot which extends either from the apex to the interior angle and projects farthest angularly inwards on vein 5 or between 4 and 5, or which is only marked at the costal-marginal part. Fringe of hindwing beneath with more or less distinct brown vein-dots. *zelica* is described from Surinam, *dorsalis* is widely distributed from Panama to Colombia, Bolivia, Peru, and Brazil. — **minor** f. n. (159 b), from the Amazons, Teffé, is less than half the *minor*. size of *dorsalis*, of a much deeper green, the white discal dot hardly visible, the hindwing much yellower, with very intense dark brown fringe-dots beneath. Type in the Berlin Museum, also from Colombia (Upper Rio Negro).

R. marona Schs. (159 b) is about as large as *zelica*; palpi brown, head green like the tegulae, collar and *marona*. mesothorax dark brown, abdomen light brown; apex of forewing somewhat more produced, the discal dot black; a dark brown subapical fringe-spot; Bolivian specimens exhibit the whole fringe speckled brown; costal margin narrowly yellowish. Hindwing brown, somewhat darker at the margin. Forewing beneath light red-brown, inner margin light green, costal margin darker red-brown, apex below the costal margin broadly, and the distal margin narrowly, tinged leaden grey; hindwing brown, dusted grey at the margin, more yellowish at the inner margin. French Guiana, Amazons, Bolivia (Songo).

R. falcata Schs. (159 c) is much larger, the apex more produced, the small discal spot white, the fringe *falcata*. at the apex brown, otherwise grey with brown ends. Hindwing lighter brown. Under surface very similar to that of *marona*, but lighter. Bolivia (Songo).

R. drucei n. n. (= *falcata* Drc. nec Schs.) seems to be very similar to *falcata*. Head, thorax and tegulae *drucei*. green, collar and mesothorax in front blackish-brown, abdomen yellowish pink, legs brown, forewing green, very finely bordered with brown at the apex, without the discal dot. Hindwing dark pinkish yellow. Both wings beneath pinkish-brown, forewing green at the interior margin. Expanse of wings: 44 mm. Colombia (Siato); Chaco.

R. demorsa Fldr. (= *epigena* Sepp) (159 c). Judging from the similarly coloured under surface, it be- *demorsa*. longs near to *drucei*, but the forewing shows a deep concavity between the apex and vein 5. Hindhead and thorax green, frons and collar as well as the costal margin of the forewing light reddish-brown, a narrow white spot at the cell-end; fringe dark brown, spotted yellowish on the ends of veins 2—5. Abdomen and hindwing light yellowish-brown, hindwing more reddish-brown towards the margin. Central and South America as far as Brazil and Bolivia.

R. thestia Drc. (159 c), judging from the type at hand, is dark green on the hindhead and tegulae, with *thestia*. a whitish frons, brownish towards the palpi; collar and mesothorax yellowish-brown, costal margin finely yellowish; forewing shaped as in *demorsa*, but with another concavity below the notch on vein 5; a brown marginal spot between the apex and vein 2 is undulately defined inwards; brown is also an almost circular cell-end spot. Hindwing dark brown, narrowly darker at the margin. Forewing beneath greenish-white, costal margin, cell, veins of marginal area and a narrow marginal spot brown; the yellowish-white ground of the hindwing is strewn with brown in the distal two thirds of the costal margin and in the marginal half. The type is from Chiriqui (Panama). Besides distributed from Mexico to Paraguay. The species is undoubtedly very variable. — **ampliata** f. n. (159 c) I denominate the form from Peru and Bolivia. Its frons, forelegs and costal *ampliata*. margin are ivory white, the hindhead is but very little green, the mesothorax is more grey; the dark brown marginal spot on the forewing is twice as broad and bordered somewhat whitish inwards. Type from Bolivia (Coroico) in the Berlin Museum. — **bernardina** f. n. (159 c), from Paraguay (San Bernardino), has quite light *bernardina*. yellowish hindwings which are only narrowly brown at the costal and distal margins. Frons almost quite white like the costal margin of the forewing, the marginal spot narrow as in the type, receding on vein 3 almost to the margin, so that it is only very narrow between 2 and 3. Beneath almost quite greenish-white on the forewing, only the narrow subcostal area and the very narrow marginal spot are brown. Specimens from Venezuela (Merida) and Nicaragua exhibit a much lighter green, the frons is here almost quite green like the

hindhead; the collar, thorax and costal margin are light red-brown, the hindwing is light yellow, reddish-brown *meridana*, only at the costal margin; this race may be named — **meridana** *f. n.* (159 c).

epigena. **R. epigena** *Stoll* (159 d) is very similar to *thestia* and recognizable by the brownish-white colour of the marginal and discal spots, the former of which is very notchedly defined inwards. The typical form from Guiana shows the frons red-brown, the middle head green and the hindhead silvery white, with a brownish-grey collar and mesothorax. Abdomen yellowish, brownish dorsally. Hindwing yellowish, brown at the costal and distal margins. Mexico to Paraguay. This species is also variable. Specimens from Peru and Bolivia have a widened *boliviana*, marginal spot, an almost white costal margin of the forewing, and a much darker brown hindwing: — **boliviana** *f. n.* — while those from Brazil and Paraguay — **meridionalis** *f. n.* (159 d) — have much lighter hindwings, *meridio-* the costal margin, collar and thorax also turning almost white. *nalis*.

tanam- **R. tanampaya** *sp. n.* (159 e). Beside *epigena boliviana*, another very similar species occurs in Bolivia. *paya*. It only differs in the very narrow and almost purely white marginal spot with a quite uniformly undulated rounded interior border, the fringe in its environs being also white, separated from it by a dark brown marginal line, the spot reaching besides down to the submedian fold, the fringe below it being green; the white discal spot is reniform, not round; costal margin and frons white, hindwing almost white, only very scantily strewn with brown, with a somewhat undulating brown marginal line, the fringe speckled dark brown. Abdomen almost white towards its end. Forewing beneath greenish-white, costal margin white, subcostal area and the very narrow marginal spot dark brown. Hindwing yellowish-white, a brown strigiform spot above vein 6, fringe speckled dark brown. Rio Tanampaya, Bolivia (La Paz). Coll. STAUDINGER in the Berlin Museum.

excavata. **R. excavata** *Schs.* Head and thorax quite unicoloured green, abdomen yellow, darker in the ♂ than in the ♀. Forewing with a slight concavity below the apex, the fringe within being white, otherwise brown. Costal margin very narrowly yellowish-brown, an indistinct discal dot is white. Hindwing of ♂ yellowish-brown, of ♀ yellow. Under surface of ♂ yellowish-brown, of ♀ yellow with a brownish shadow in the marginal concavity, the hindwings with blackish-brown marginal dots. Expanse of wings: 36 mm. From Brazil (Petropolis).

dealbata. **R. dealbata** *Dogn.* resembles the following *deolis*; frons white, vertex and tegulae green; collar and mesothorax of a colour like "coffee with milk", abdomen above white intermixed with grey, beneath all white like the legs. Forewing with a white costal margin and cellular spot, the marginal spot is narrow as in *deolis*, but white like the fringe which is intermixed with some grey. Hindwing purely white, speckled somewhat grey on the ends of the veins. Loja (Ecuador).

deolis. **R. deolis** *Cr.* (159 d). Shape of wings similar as in the *thestia*-group, but the notch on the forewing is situated between the veins 5 and 6, and the costal margin shows a distinct prominence behind the middle. Head and tegulae green, collar and thorax dark brown; discal spot dark brown, in a yellow ring; margin inclusive of fringe between 2 and the apex narrowly dark brown. Hindwing and abdomen light ochreous, hindwing more or less brown at the margin. Beneath greenish-yellow with a rusty red costal margin, a dark brown marginal spot and 3 or 4 green strigiform spots between the apical veins, hindwing ochreous, costal margin, apex *brun-* and distal margin red-brown. — **brunescens** *Dogn.* is a form with quite brown hindwings and abdomen, *nescens*, described from S. Paulo de Olivenca (Amazons).

apicalis. **R. apicalis** *Wkr.* (159 d, e) looks almost the same and may be merely a form of it, distinguished on the forewing by the brown marginal spot widening inwardly in the shape of a notch between 5 and 6, the purely yellow hindwing lacking the brown margin. The discal spot is often enormously large in the ♀♀, we figure such a ♀. Described from Honduras, occurring also from Mexico to Colombia and Guiana.

dolorosa. **R. dolorosa** *Drc.* belongs yet to the same group with a dentate distal margin and is discernible by the head and collar being all white, with a brown thorax and green tegulae; abdomen and legs yellow. Forewing dark green, white at the costal margin, with a large brown cell-end spot and a brown marginal spot. Hindwing light yellow, black at the costal margin and apex. Expanse of wings: 38 mm. Brazil (Cabo).

aethra. **R. aethra** *Drc.* (159 e) introduces a group of smaller species with notchless wings and a more or less distinct inner-marginal marking. *aethra* has the most strongly pectinated antennae. Head and thorax green, only the frons and a longitudinal stripe at the interior margin of the tegulae are whitish; abdomen pale ochre. Forewing light green costal margin very narrowly reddish-yellow; a very fine dark dot at the cell-end, a fine yellowish longitudinal streak in the basal half of the inner margin is bordered with black above and widens in the centre of the inner margin, forming a semicircular thickening. Hindwing purely white. Forewing beneath pale greenish, the costal margin as well as the chest and anterior femora are orange. Mexico to Colombia.

nadina. **R. nadina** *Schs.* (159 e) is similar, but the head is white, green only in the neck. Forewing darker green, the costal-marginal stripe of a purer white, widening somewhat and more yellowish towards the apex, the cellular spot larger, dark brown, in a yellowish ring, the white inner-marginal stripe extends only over a third of the inner margin and is bent up here to a short vertical white streak. Hindwing feebly suffused with pink, abdomen salmon-coloured orange. Guiana.

zikani. **R. zikani** *sp. n.* (159 e) is allied to *nadina*, larger, slimmer, lighter green, the head almost quite green,

collar and thorax light sand-coloured grey, the tegulae only very narrowly green, the abdomen whitish ochreous. The costal-marginal stripe and the fine discal dot are purely white; a small white triangular spot at $\frac{1}{4}$ of the inner margin has its base on the inner margin and is bordered slightly darker above. Hindwing purely white. Chest and anterior femora yellowish ochre; a large oval black central spot is on the ventral side of the abdomen. 1 ♂ from Passa Quatro (Sul de Minas) (Zikan leg.), in the Berlin Museum.

R. amazonica *sp. n.* (159 e) is another very similar species, somewhat smaller, with broader wings, *amazonica*. much rounder at the apex, and longer pectinated antennae. Head green, frons white; collar and the interior edge of the tegulae sand-coloured grey, the tegulae and mesothorax green, abdomen whitish ochreous. Costal margin of forewing whitish pink, the white discal spot much more conspicuous; the 1st third of the inner margin and the small triangular spot whitish pink. Hindwing white, margin and fringe faintly tinged with yellowish pink. Chest and anterior femora rusty yellow, ventrum yellowish-white. Forewing beneath pale green, the costal margin and apex very broadly pinkish-orange down to vein 4. 1 ♂ from Massauary (Amazons) in the Coll. STAUDINGER of the Berlin Museum.

R. languida *Schs.* (159 f). Head green, collar and thorax broadly grey, only the exterior edge of the *languida*. tegulae green, abdomen pink. Forewing green with a fine yellowish-white costal margin, a black discal dot and a brownish-grey narrow inner-marginal stripe in the basal half, then widened into a small spot containing a few green scales. Hindwing whitish pink. Forewing beneath whitish with a reddish costal margin. Brazil (Rio).

R. purpusi *sp. n.* (159 f) forms the transition to the following species. Head greenish-white, collar and *purpusi*. mesothorax dark brown, tegulae and forewing light bluish-green, costal margin reddish-yellow, discal dot blackish-brown in a broad white ring; base of inner margin whitish, then blackish-brown as far as the middle, where it widens into a spot which extends to vein 1. Hindwing pale reddish-yellow. Forewing beneath greenish, hindwing white, both with reddish orange costal margins. Abdomen pinkish ochreous, the two first segments light brown. Ventrums yellowish-white, chest, palpi and anterior femora pinkish ochreous. 1 ♂ from Soconusco (South Mexico), in the Berlin Museum.

R. myops *Fldr.* (159 f) is a somewhat larger species; head and thorax green, only the interior edge of *myops*. the tegulae and a spot on the metathorax are grey, the former separated from the green by a deep blackish-green stripe. Forewing green with a fine yellowish-white costal margin, a blackish-brown discal spot in a very fine light ring; the basal half of the inner margin with a narrow light brown longitudinal stripe which is bordered with a deep greenish black above and is widened spot-like at the end. Hindwing deep pink like the abdomen, with a very large black spot on the ventral side. Forewing beneath greenish with darker green fringe, the costal-marginal half tinged orange. Colombia; Brazil.

R. simillima *sp. n.* (159 f) is very closely allied to *myops*, but easily discernible by the entirely brown *simillima*. mesothorax, only the exterior edge of the shoulder-plates being narrowly green, the abdomen quite pink without the brown hair on the two first segments and without the black spot on the ventrum which is yellowish ochreous. Costal margin of forewing pink, the blackish-brown discal spot much larger, and the inner-marginal stripe which is deep blackish-brown here extends only to the first of the inner margin without its end being essentially widened. Hindwing lighter pinkish ochreous. The whole under surface is reddish ochreous. Amazons and Blumenau. Type in the Berlin Museum.

R. incita *Schs.* is similar to the preceding species, but much smaller. Costal margin of forewing straight *incita*. on two thirds, the last third convexly bent down to the apex. Head and tegulae green, collar and thorax brown, abdomen brownish at the base, the rest reddish-ochreous, ventrum white. Forewing green with a small black discal dot and a long black inner-marginal stripe as far as the middle. Hindwing purely white; under surface whitish, the costal margin feebly tinged with pink. Expanse of wings: 32 mm. Peru.

R. unda *Schs.* (159 g). Head green, collar and mesothorax brown, tegulae and forewing light green; *unda*. costal margin very narrowly yellowish, a black dot bordered with yellowish is at the cell-end; a small blackish-brown spot at the base of the inner margin. Hindwing yellowish pink. Under surface yellowish white, both the costal margins pink. Abdomen pink above, yellowish ochreous beneath. Brazil, Peru.

R. sciritis *Drc.* (= *lappa Schs.*) (159 g). Head green, collar, mesothorax, and the interior edge of the *sciritis*. tegulae light brown; tegulae and forewing green; costal margin narrowly ochreous, discal dot black, an ochreous inner-marginal stripe extends to the anal angle and is upwards convex in the middle and bordered with darker green above. Hindwing white, abdomen pink above, white beneath, with a long blackish-brown central spot. Forewing beneath greenish-white, hindwing white, both with orange costal margins. Brazil, Peru.

R. dentifera *sp. n.* (159 g). Head green, frons and the borders of the eyes pink, collar, thorax, and inner *dentifera*. edges of the tegulae from light brown to sooty black, a green spot in the centre of the thorax; tegulae and forewing green, costal margin broad reddish-yellow, discal dot blackish-brown, scantily edged with yellowish; inner margin yellowish-white, widening behind the middle into a large circular reddish-yellow spot, intermixed and edged with blackish-brown hairs which are expanded at the inner margin in a fairly large scale-dent. Hindwing diaphanous white, with reddish-pink hair at the inner margin, the distal margin and fringe of the ♂ being

pale orange. Abdomen pale pinkish ochre, the two first segments of the ♂ above with blackish-brown hair; ventrum white; palpi, anterior hips, and femora deep salmon-orange, tarsi black. Types from Mexico (Orizaba) in the Coll. DRAUDT, co-type 1 ♀ from Costa Rica (Turrialba) in the Berlin Museum.

apollinairei.

R. apollinairei Dogn. (= klagesi Rothsch.) (159 g) is similar to *dentifera*, larger, the orange costal-marginal stripe widens apicad, the inner-marginal stripe extends to the anal angle and is broadly greenish-olive, somewhat reddish orange above, and bordered with deep dark green especially in the basal half above. The white hindwing has a broad pink costal margin; abdomen pinkish salmon-coloured. Colombia (Bogota; Villavicencio).

thalassina.

R. thalassina H.-S. (= prasina Bsd.) (159 h) is an apparently variable species. Head green, collar and thorax more or less blackish-grey, intermixed with single green hairs, only the distal halves of the tegulae deep blackish-green. Forewing of a peculiarly transparent bluish-green, with darker green veins; inner margin as far as up to the submedian fold deep dark green, convex above, tapering towards the anal angle, where it terminates in a blackish-brown hair-dent, the centre of the inner margin exhibits a lighter brownish triangle intermixed with blackish-brown hairs. Hindwing transparently white, more or less tinged pink and with pink veins or quite greyish-pink, more intensely pink-haired at the inner margin, abdomen pinkish orange salmon-coloured, anus blackish, ventrum white, spotted blackish-brown. Palpi, hips and femora pink, tibiae and tarsi sooty blackish-brown. Colombia to Brazil. — **albidula** Dogn. (159 h) is presumably no separate species, but only a form of this variable species with entirely white hindwings, only the costal margin being slightly tinged with pink; the blackish-brown colour of the thorax is continued to the two first abdominal segments; the dark inner-marginal stripe of the forewing is less convex above. The two forms are evidently connected by all kinds of transitions, numbers of which are at hand from the Berlin Museum. Guatemala; Colombia; Brazil; Peru.

fulvipennis.

R. fulvipennis Btlr. Head and thorax green, frons white with two small orange spots, palpi ochreous; collar dark brown, abdomen orange. Forewing dull emerald-green with an orange costal margin and a white discal spot; fringe white, violettish-grey at the ends, two similarly coloured small spots in the apex. Hindwing orange. Under surface bright yellow with broad reddish orange costal margins, forewing with a lustrous pinkish-brown marginal area, apical half of hindwing orange-red. Legs brown. Expanse: 38 mm. São Paulo.

pallida.

R. pallida Jones. Head and thorax green, palpi, legs and antennae ochreous, collar reddish ochreous; abdomen ochreous. Forewing light green with an ochreous costal margin and a tiny white cell-end dot. Hindwing and under surface white. Expanse of wings: 38 mm. Castro (Paraná), Brazil.

simois.

R. simois Drc. (= luna Schs.) (159 h) is very similar to *pallida*. Head and thorax green, abdomen pink above, white beneath. Forewing green, the costal margin narrowly bordered with white, a small white dot at the cell-end. Hindwing white. Under surface white with green fringe and reddish costal margin which is white in the ♀; the abdomen is here also white above, only basally with a slight pink tinge. Brazil; Peru.

rotundata.

R. rotundata sp. n. (159 h) has peculiarly broad, rounded wings. Head light green, frons white, collar brown. Thorax dull green, grey at the base of the abdomen, abdomen white, feebly yellowish. Forewing dull light green, costal margin very narrowly yellowish-white, with a tiny white discal dot. Hindwing purely white. Forewing beneath of a very delicate light green, hindwing white. ♂♀ from Bolivia (Villa Montes) in the Berlin Museum.

albiceps.

R. albiceps sp. n. (159 i) is an entirely isolated species. Head and palpi white, palpi laterally finely striped blackish-brown; collar and thorax green, metathorax with 2 sand-coloured grey spots; abdomen ochreous, white beneath. Forewing dark grass-green, costal margin ivory white, widened a little in the middle; a large oval white spot at the cell-end widens between the veins 3 and 4 behind the cell, the margining and the veins in the spot dark brown; fringe at the distal and inner margins dark greyish-brown. Hindwing pale orange. Forewing beneath pale greenish with a broad yolk-coloured costal margin, a transparent discal spot, and dark brown fringe. Hindwing pale yellow. 1 ♂ from Blumenau in the Senckenberg Museum (Frankfort-on-the-Main); 1 ♀ from Brazil (where?) in the Berlin Museum shows the broader white costal margin striated brown.

mona.

R. mona Jones. Frons green, hindhead brown like the palpi and legs; collar and thorax green, abdomen light reddish-yellow. Forewing green, costal margin ochreous, strewn with brown, a large white spot strewn with blackish-brown is at the cell-end, a smaller one behind it between veins 2 and 3, and a still smaller one above the latter; another small white antemedian dot at vein 1. Hindwing monotonously light reddish-yellow. Expanse of wings: 44 mm. Santos (Alto da Serra).

erdae.

R. erdae Schs. is somewhat similar, but much more profusely spotted white. Head, thorax and forewing green, palpi and vertex reddish-yellow. Abdomen pale yellowish orange above, lighter beneath. Costal margin of forewing light reddish-yellow, strewn with black; a round white spot at the cell-end, and a smaller one behind it between 2 and 3, both strewn with blackish-brown; antemedian white dots on the veins, and a subterminal double row of white vein-dots. Hindwing yellowish-white. Expanse of wings: 40 mm. Sa. Catharina.

costalis.

R. costalis Wkr. (159 i). Here, or already with the preceding *mona*, begins a group of mostly larger species which were ranged under a special genus: *Moresa* Wkr., but there are no anatomical differences. Head and palpi whitish, the head with a brown frontal spot; thorax dark green, abdomen light ochreous. Forewing green with a broad whitish costal margin scantily speckled with blackish-brown; a variably large white lobate

spot, likewise strewn with black and edged with black at its upper margin, extends from the first third of the costal margin to the anal angle. The white hindwing shows a faint yellowish tinge. Brazil.

R. obliquifascia *Rothsch.* (159 i) is very similar to *costalis*, distinguished by a reddish-yellow head, the abdomen and hindwing being orange, more or less tinged with pink; the whitish costal-marginal stripe is much more intensely strewn with black above, like the narrower and much less lobated oblique spot which is not edged with black. Guiana to Brazil (Espiritu Santo).

R. magniplaga *Schs.* (159 k) likewise resembles the two preceding species, but the head is white, the costal-marginal stripe distinctly pink, the oblique spot shorter, extending neither to the costal-marginal stripe nor to the tornus, brownish, uniformly strewn with a darker brown. Abdomen orange like the hindwing. Guiana to Brazil.

R. hieroglyphica *Rothsch.* (159 k). This very peculiar species has developed from the preceding species, and is unmistakable for the oblique spot extending into 3 fingers, being tinged pinkish carmine and crossed by a light postmedian line. Abdomen orange, hindwing pale pinkish salmon-coloured. Amazons.

R. plumbiplaga *Rothsch.* Head reddish-yellow, antennae black with ochreous pectinations; thorax deep green, abdomen yellow reddish-brown. Forewing deep green with a sooty blackish-brown costal margin with a large brownish leaden grey oblique spot from below the centre of the subcosta to the distal margin between 4 and 2; a short white stripe, followed by some white dots, extends from the last fifth of the costal margin into the surface of the wing. Hindwing reddish-yellow in the costal third, yellowish-pink below it. Expanse of wings: 52 mm. French Guiana.

R. walkeri *Schs.* (= *costalis* *Fldr.* nec *Wkr.*) (159 k). Head and palpi light brown, thorax dark green, abdomen pale orange. Forewing green with a broad whitish costal margin speckled blackish-brown. Hindwing pale yellowish. Brazil to Paraguay.

R. pallidicosta *Schs.* (159 k) is extraordinarily similar, but the whole head is green, with a white spot on the vertex, the abdomen is more brownish ochreous with a large blackish-grey hair-spot on the first segment, anal hair whitish. Costal margin of forewing somewhat straighter, the apex thereby more pointed. Forewing bright dark green with a pink-tinged costal margin and a small yellow discal dot. Hindwing yellowish-white. French Guiana to Brazil.

R. aldaba *Dogn.* (159 k) is a small species, with a green head and thorax, and an ochreous abdomen. Forewing green with a broad yellow costal margin and yellow fringe; subterminal traces of a slightly darker transverse line which projects towards the margin on 4 and 5 with two short notches. Hindwing pale yellowish. Ecuador (Loja).

R. eurytis *Drc.* This species and the following *vitula* are doubtfully ranged here, as the short insufficient description affords no clue as to the shape of the wings etc. I can therefore only render the description: head white, thorax and abdomen brown, tegulae green, legs whitish brown. Forewing dark green with a white costal margin and a white discal spot; apex and part of the distal margin dark brown. Hindwing dark brown, whitish at the base; fringes of both wings brown. Under surface yellowish-white, intensely dusted dark brown. Expanse of wings: 1½ inch. Venezuela (Merida).

R. vitula *Drc.* Head, antennae and thorax brown, tegulae green; abdomen brownish-white, legs light brown. Forewing dull green, costal margin white, fringe green. Hindwing white. Both wings beneath greenish-white, the costal margin of the forewing yellow. Expanse of wings: 1½ inch. Venezuela (Merida).

Additions:

P. 922, after *M. hirsuta* *Schs.* insert:

M. agathanzela *Schs.* is nearest to *hirsuta*, but distinguished by white hindwings which are somewhat transparent, scantily scaled, with indistinct dark marginal scales which extend also upwards along the inner margin. Forewing reddish-grey above the cell and vein 3, red-brown below it, the apical area coppery reddish orange, the lines very similar to those of *hirsuta*, all parallel, a marginal double row of black dots. Expanse of wings: 34 mm. Campo bello (Rio), Brazil.

P. 953, after *D. centralis* *H.-S.* insert:

D. nondescripta *Kaye.* Forewing chocolate mixed with yellowish-green, especially at the costal margin behind the centre; discal spot small, mixed with greenish-yellow on both sides, an indistinct lunular postmedian line, another subterminal one, small dark spots before it between the darkened veins of the marginal area. Hindwing transparent greyish-white with a darkened apex and inner margin. Expanse of wings: 54 mm. Trinidad.

P. 966, after *achates* Dogn. insert:

guasca. **D. guasca** Schs. differs from the 3 similar species in the complete white circular marking in the distal area. Forewing reddish cinnamon basally, bordered with white and defined by a curved black line, a brown area behind it, strangulated in the middle, bordered outside by a black line which borders on the white circle which is distally filled with light reddish-brown, proximally with cinnamon; behind it, at the costal margin, there is a brown triangular spot, outside a white subterminal line which touches the white circle on 5. Hindwing white, reddish-brown at the distal and inner margins. Expanse of wings: 39 mm. Colombia.

P. 970, after *aroensis* Schs. insert:

sexnotata. **D. sexnotata** Kaye. Forewing light brownish, dusted with violettish-grey basally, the costal and inner margins more yellowish-brown; the apical area with a large reniform or bean-shaped dark brown spot which is bordered by a black line representing a 6 on the right forewing; 2 small dark spots in the apex. Hindwing greyish-white, apex feebly scaled grey. Expanse of wings: 46 mm. Trinidad.

P. 977, after *albovirens* Dogn. insert:

mahalia. **D. mahalia** Schs. is very closely allied to *albovirens* and chiefly distinguished by purer white hindwings and a darker basal area of the forewing. Forewing hyaline white, dark scales form an indistinct double postmedian line; basal area dark violettish-grey, strewn with black, extending from the antemedian line obliquely to the anal angle; the marginal third of the costal margin is violettish-grey and cinnamon. Hindwing scantily scaled, white, only the fringe somewhat darker. Expanse of wings: 38 mm. Colombia.

poppea. **D. poppea** Schs. is also closely allied; the white forewing is scantily strewn with cinnamon-brown, the basal area obliquely cut off, brown as in *mahalia*, strewn with black, enclosing a dark band from the base of the costal margin, and a similar double antemedian line; a double blackish-brown line extends through the cell-end, another double line on and behind the cross-vein, and a blackish-brown preapical shadow, enclosing a fine dark, deeply dentate line behind which there is a more faded subterminal line bordered with whitish. Hindwing white with a narrow brown marginal line. Expanse of wings: 35 mm. Campo bello (Brazil).

P. 990, after *B. tonac* Schs. insert:

kalodonta. **B. kalodonta** Kaye. Forewing greenish-grey, mixed with violettish-grey, with a lighter brownish spot in the marginal area between 2 and 4, the basal area darker leaden grey with 3 parallel undulate lines in it; the distal area is lighter than the interior part, with dark veins, and one black punctiform spot each between 3 and 4, and 6 and 7. Hindwing white, the costal margin dark brown, with a white spot in the middle. Expanse of wings: 40 mm. Trinidad.

eglossa. **B. eglossa** Kaye has a stunted proboscis. Forewing dull greenish, darker in the basal third, defined by a double dark line; a blackish spot before the postmedian line between the veins 2 and 3; a subterminal row of small reddish-brown spots between the black veins. Hindwing scantily scaled greyish-white with a dark costal spot before the apex. Expanse of wings: 36 mm. Trinidad.

P. 1014, after *E. pallida* Schs. insert:

zophara. **E. zophara** Schs. Forewing white, dusted dark grey from the base to the postmedian line, with traces of a white anterior transverse line, with some small black spots behind it; a white median line is bordered with black outside, an oblique black line is behind it below the cell; discal streak thick black, bordered with white inside; posterior transverse line black, bordered with white, with a line of black spots behind it, the indistinct undulate line black. Hindwing black with a fine brown marginal line and a black anal spot. Expanse of wings: 38 mm. Campo bello.

P. 1025, after *P. apulana* Schs. insert:

pohlana. **P. pohlana** Schs. Forewing reddish ochreous in the basal area, cinnamon brown behind it, the centre of the costal margin sand-coloured like the inner margin, the centre of the cell darker brown; a silvery white spot in the upper cell-angle, the cross-vein with an S-shaped silvery line; distal area reddish-violet, more lilac at the margin; at the costal margin, before the apex, there is a large purple brown triangular spot bordered with a lighter colour, a similar area before the inner margin at the anal angle, a fine silvery line before the apex; 2 antemedian parallel blackish-brown lines. Hindwing whitish, dusted with cinnamon. Expanse of wings: 68 mm. Itatiaya (Rio).

P. 1038, after *H. angulinea* Schs. insert:

cabnala. **H. cabnala** Schs. Forewing yellowish-brown with a curved subbasal line bordered with a lighter colour, a slightly darker double median line, meeting submedianly and forming a ring filled with yellowish below it;

the light posterior transverse line from 6 mm before the apex, angled on 6, ending 4 mm before the anal angle; an oblique shadowy spot near the centre of the distal margin. Hindwing dark fawn. Expanse of wings: 42 mm. Brazil.

H. jacksoni Kaye. Forewing reddish violettish-grey with an indistinct ring-macula in the cell and an indistinct discal spot; inner margin and a very indistinct subterminal band reddish-grey, the latter bordered inwards by a double posterior transverse line; distal area somewhat darker. Hindwing greyish-white with a reddish tint, more intensely red at the margin. Expanse of wings: 48 mm. Trinidad.

Alphabetical List

of the American forms of *Notodontidae* with references to the original descriptions.

* signifies that the form is also figured at the place quoted.

16. Family: *Megalopygidae*.

Like many other lepidopteral families, the *Megalopygidae* are distinguished by a great number of characteristics. We cannot conclude any affinities from single ones of these characteristics, as the species of to-day do not show, which of these characters are due to acquired convergency. In morphological respect, the *Megalopygidae* are nearest to the African *Phaudinae* which HANDLIRSCH regards as a tribe of the *Zygaeninae*, these as a subfamily of the *Zygaenidae*, and the latter like the *Megalopygidae* as a family of the superfamily of *Zygaenina*. However, a closer relationship of the *Megalopygidae* to the *Zygaenidae* is not proved. Cf. JORDAN in Nov. Zool. 34 (1928) p. 135 on the morphological differences between the *Megalopygidae* and *Phaudinae*.

The only fact is that the American *Megalopygidae* of our days represent, in a sexual-morphological respect, almost uninterrupted stages of development, among which also the palaearctic, Mediterranean-African genus *Somabrachys* can be so cogently ranged that it may be said to be a constituent disjoined from the American *Megalopygidae*. The other parts of the world are without any *Megalopygidae* at all, and thus they can be justly denoted as an old typical element of the neotropical fauna, having sent only very few branches of highly developed species to the nearctic region.

Ancient authors as well as collectors of the present days have frequently confounded the family with *Lymantriidae*, *Lasiocampidae*, *Zygaenidae*, *Cossidae*, *Limacodidae*. For this reason it is absolutely necessary to describe them rather minutely.

The neuration is characterized in the forewing by the presence of the analis, in the hindwing by three — instead of two — separate inner-marginal veins, and in both wings by the presence of a cellular media dividing the cell as far as the base or almost to it in two longitudinal parts. The cell is relatively extensive in both wings; therefore the veins arising from it appear to be shorter than for instance in the *Lasiocampidae*, so that they are easily distinguished already by this characteristic. The media is never forked within the cell of the forewing in the American species; and there are no accessory cells. The axillaris of the forewing is very shortly forked at the base and frequently, though not invariably, despatches one or several secondary branches to the inner margin. The palpi are very small, they may even be mere knobs or absent. The tibial end-spurs are likewise small, individually from all stages of atrophy and coalescence to entire absence; no middle spurs of the tibiae, no second pair of tibial end-spurs or tarsal end-spurs. The fact that the atrophies of the palpi and spurs are due to correlation becomes evident in the *Aidinae*, where they are somewhat more distinctly developed. The proboscis is also very rudimentary or absent, and there is no tympanal organ. However there is between the eye and the antenna, laterally sunk into a hollow, JORDAN's chaetosema, a circular organ of sense with radially placed bristles. The antennae are differently developed in the ♂ and ♀. The male antennae are pinnate, though only basally in the *Aidinae*, flattened and plain in the *Zyzypye*; the length of the stem and the width of the pinnae vary much individually in some species. The female antennae are more narrowly pinnate or even plain, sometimes they also vary individually. The frenulum is normally developed, capable of function in the ♂, except in *Megalopyge* which genus lacks the retinaculum. The thorax of the *Megalopygidae* exhibits a remarkable characteristic of the family: the deep longitudinal median fold in the anterior part of the mesonotum. The abdominal segments are densely haired and clothed with parallel short bristles of a sometimes bright (orange) colour. The ♀ exhibits a bundle of externally smooth anal wool which is once or twice sharply curled inside, from which the family derives its name; this silky wool is the felt covering the eggs which are mostly flatly deposited in paired rows.

Most of the species are very hairy and have rather broad wings with rounder inner margins; the wings are never indented, tailed, very much prolonged, or pointed. The largest species has an expanse of 90 mm, the smallest of 10 mm. *Megalopygidae* have almost only been captured at night on artificial lights, many species

apparently favouring a certain flying time. ZIKÁN, however, observed also the ♂ of *Megalopyge hyalina* towards noon, visiting the ♀♀ that were kept in the breeding-box. Of many species the ♀ is still unknown.

The biology has been described of but few species, chiefly that of the North-American species. We have already spoken of the way the eggs are deposited. Beside three pairs of normal thoracic legs and the anal legs, the larvae exhibit six — instead of usually four — pairs of claspers on the abdomen; but the first and last pairs of these legs (lacking the larvae of other families) on the 2nd and 7th abdominal segments are more feebly developed, the coronae of hooks are rudimentary here or absent. The mostly dense hair of the abdominal segments is grouped around a subdorsal and a dorsal pair of bristly tubercles on each segment, sometimes parted, from bristly to curled. Some species of *Megalopyge* are provided with a long hair-tuft on the neck, sometimes also in the centre of the dorsum. Glandular lobes the function of which is unknown hang down behind the spiracles of the abdominal segments. The head can be drawn into the wrinkled first thoracic segment and becomes quite invisible, if a huge long-haired, apically parted thoracic crest is present. The larvae of *Aidos*, however, are almost bare, the short bristles are sunk into flat hollows. Certain places on the body of some species exhibit, among the usual hair, shorter, thicker, hollow poisonous hairs which terminate basally into a poison-bag or a system of glandular tubes containing poison. The chemical nature of this poison, a colourless liquid, has not yet been sufficiently explored. It has a destructive effect upon the human skin, producing pain and a swelling of the lymphatic glands. JONES crushed a larva of *Megalopyge* in the hard palm of his hand; the effect was that his arm was paralyzed for weeks. Already when slightly touching the larva of a *Padalia orsi-lochus* with one's finger, the whole arm may be swollen for several days with fever and pain (POHL). The latter larvae are colloquially known in Brazil as "bizos de fuero" (fire-animals) or as "bizos de rato" (rat-animals), while the Indians in Paraguay call them "Iso Yagua" (jaguar-worm); the comparison with the jaguar indicates at the same time the colouring, dangerousness and swiftness, for they are able to run fast, and in doing so the high-standing hair-tufts may have a steering effect. Some explorers are reminded of poodles by the agility and the rough skin of the *Megalopyge*-larvae; in Mexico they are called "perrito pachón" (small hound).

The food of the larvae is multifarious as in other low Heterocera; they were found on Cupuliferae (oak), Rutaceae (Citrus), Resoaceae, Ulmaceae, Myrtiflorae, Papilionaceae trees, Gramineae (*Panicum*), and others. Many species, however, are not polyphagous, but rather oligophagous, because they are sometimes excellently adapted to the life on their food-plant. A. SCHULTZE observed that the excrement-clods of the *Megalopyge* larvae are hollow. The pupation takes place in leathery, tenacious, dense, though not quite hard cocoons covered with an exterior rough and an interior smooth and dense film. In addition there is sometimes yet a third very loose, spongy, bulky web which strikingly copies the bark of a tree, under the cover of which the cocoons, either singly or by twos or threes, are flatly appressed below crotches of the trees (*Megalopyge lanata*). Many larvae remain unupated in the cocoons for months even as long as a year and a half, dying off on being disturbed, as the larvae are generally very delicate and therefore difficult to breed. Empty cocoons are seen hanging on the trees for years after and, bleached by the sun and rain, they assume an entirely changed exterior (ZIKÁN). The cocoons are provided with a roundish lid which is only superficially spun on; the way this lid is produced is not yet known. When the pupae, in which all the appendages of the imagines are stored in half-free cases, emerge, they take off part of the lid and press themselves half out of the cocoon. The species living on low plants embed their cocoons in the earth. The cocoons of *Aidos amanda*, which are spun to the underside of leaves of different trees, look like the webs of ichneumon-flies, especially since also their hiding places are copied.

Most of the American species live in the hot lowlands of the tropical forests and savannas. The southernmost boundary of their range is about the line from Buenos Ayres to Mendoza in Argentina. In the north one species penetrates to the Atlantic States, nine to the hot Southern United States: Texas, Arizona, California. Six of these ten species, however, have been ascertained also in Mexico, the other four being closely allied to Mexican species. *Megalopygidae* have also been captured more than once at great altitudes in the Andes, but almost invariably they were such specimens that were carried from the plains up to these heights by warm currents of air in the evening; in the larval stage very few species occur in the cold country, in the "tierra fria" of the Andes. Numerous species have a very extensive range: from Mexico to South Brazil. More locally confined are the species of the Andes, of the savannas and pampas, representing in some respect the generalized species for the most part. Chile is without any *Megalopygidae*.

The *Megalopygidae* can be divided into three divisions owing to the different course of the subcostal vein on the male hindwing:

I. The subcostal vein anastomoses with the whole anterior cell-vein: *Trosiinae*.

II. The subcostal vein anastomoses with the basal part of the anterior cell-vein: *Megalopyginae*.

III. The subcostal vein is free, connected at most with the cell by a bar: *Aidinae*.

The ♀♀ of the *Aidinae* and *Trosiinae* exhibit the same course of the subcostal vein as in the ♂♂. It varies, however, in the ♀♀ of the *Megalopyginae*; it is like that of the ♂♂ in few species, but in most of the species it is like that of the *Trosiinae*. In phylogenetic respect the free subcostal vein of the *Aidinae* effecting an invigoration of the costal margin of the wing is the most advanced, the anastomosing subcostal vein of the *Trosiinae* the most retarded, while in most of the *Megalopyginae* it is explicable as a conservative element in the females, as a progressive element in the males.

Among the *Trosiinae* there are yet in other respect the most generalized *Megalopygidae*, i. e. in the organization of the 10th ventral segment of the ♂♂. In *Norapella bipennis* it is preserved as a complete ventral segment with paired appendages on the sternit and tergit. Step by step a simplification of this organization can be followed up, till finally, in certain species of *Norape*, a single small lobe of the tergit represents the last, chitinized remainder of the 10th segment. In this way the 10th segment does not only differ almost invariably from one species to the other in the *Trosiinae*, but it shows in distinctly separable groups of species an ever varying organization which is determined by the absence or presence, by the separation or anastomosis, finally by the dorsal, lateral, or ventral position of its constituents: uncus, socii, and gnathos. Thus the stages of development of the 10th segment contrast with each other, explicable as a checking and, at the same time, as a specialization of its development. These stages were assumed for the *Trosiinae* as the foundation for determining the genera. If we compare the *Megalopyginae* and *Aidinae* with this generic principle we notice that, in these two divisions, the organization of the 10th ventral segment has almost been stationary at a certain stage of development. Their genera and partly also their species are not equivalent to those of the *Trosiinae*.

I. *Trosiinae*.

Excepting the mostly brightly marked and coloured species of *Mesoscia* and *Trosia*, we are chiefly met with a want of marking and with white colouring among the *Trosiinae* to which also the pygmean *Megalopygidae* belong. The few species that are coloured or provided with a scheme of markings on the wings generally take up an archaic position within their genus according to the state of the 10th ventral segment, and we may conclude from this that their scanty, uncomplicated and variable colouring and marking is rudimentary and that the many purely white species have issued from marked and coloured primary forms. By the loss of pigments a convergency of the species and even of the genera in their outward appearance has been produced, as is unequalled in the lepidopteral kingdom. We may only remember species such as *Mesoscia itatiayae*, *Macara pasaleuca*, and *Norape beggoides*, which can easily be confounded, if their generic character is not ascertained from the 10th segment. The white unmarked species of *Norape*, numbering far more than 40, are almost exclusively determinable by the very constant and heterogeneous shape of their male sexual armature. Yet it is absolutely necessary for determining the genera to examine first of all the 10th ventral segment of the ♂♂. If this is neglected, only few genera remain that are discernible by their different neuration, and these may be placed ahead of the others.

A. Less than 11 veins from the cell of the forewing.

1. Genus: **Zyzypye** Hopp.

Only 9 veins or vein-branches respectively proceed from the cell of the forewing, the 3rd and 5th radial branches are absent. The only species hitherto known exhibits almost plain, flattened antennae of the ♂ in contrast with all the *Megalopygidae*. The 10th abdominal segment shows a tergit-appendage (uncus) in the shape of a roundish, bare plate from the centre of which a plain, slightly curved thorn arises. The genus appears to be highly specialized owing to these characteristics. The only species is:

V. calycina Hopp (160 a). Thinly scaled, semidiaphanous, faintly marked by dark brown and white scales. Head, thorax, anal aperture, and legs white-haired, hindlegs blackish above, abdomen black, loosely covered with white hairs. Antennae light brownish, scantily scaled white. Expanse of wings: ♂ 11.5 mm. Taperinha, Amazons.

2. Genus: **Vescoa** Dyar.

Only 10 veins proceed from the cell of the forewing, the 3rd radial branch is absent. Distinguished from two other genera that are characterized in the same way by the 1st radial branch of the forewing not extending separately, but in a long anastomosis with the subcostal vein. The 10th segment is similar to that of *Malmella*, the not paired uncus borders dorsally, as a bare ridge ending in a small thorn, on the entirely fused socii which are provided with a structure of tactile hollows. Only one species:

ma. **V. ma** Dyar (160 a). Scaled greyish-brown, all the veins finely lined white, fringe white. Forewing with a white spot at the end of the cell. Hindwing with a white basal area. Abdomen greyish-brown, thorax intermixed with white. Head whitish, antennae light, with a whitish shaft, broadly pinnated. Legs white. Expanse of wings: ♂ 15½ mm. Peru and Lower Amazons, probably more widely distributed.

3. Genus: **Microcladia** Hopp.

Veined like *Vescoa*, but the 1st radial branch of the forewing is free. Distinguished from *Microrape* by a paired, short, bivalve uncus. White dwarfish species. The two species hitherto known are distinctly separable by the male sexual armature.

pygmaea. **M. pygmaea** Hopp is purely white, with a faint silky gloss, the costa brownish on the basal half of the forewing beneath. The completely developed 10th segment contains, as a sternit-appendage, a free, tongue-shaped, not paired gnathos. Sacculi distinctly developed. Mexico.

pusilla. **M. pusilla** Hopp exhibits a more intense silky gloss, the basal half of the forewing beneath with a blackened costa. The gnathos is only indicated by the sternit being more intensely chitinized. Sacculi extremely small, knob-shaped. Rio de Janeiro.

4. Genus: **Microrape** Dyar.

Veined like *Microcladia* from which it differs in the not paired, well developed uncus the shape of which varies from one species to the other. The species differ besides in the very differently shaped appendages of the genital segments. The American primeval forests probably contain yet many undiscovered species. White pygmean species. Only two species are known hitherto, bearing blackish markings on the white forewings:

santiago. **M. santiago** Hopp has a smoky grey angular mark at the cell-end of the forewing and is brownish also at the inner margin and apex of the forewing. Expanse of wings: 10 mm. South Colombia.

signata. **M. signata** Hopp (160 a) with an expanse of 12 mm shows a broad feeble black band from the centre of the inner margin almost to the centre of the veins 4—5 of the forewing, terminating in a black spot; next to it there is another black spot in the centre of the cell, so that the end of the cell represents a blank white spot. Irregular blackish dusting at the inner-marginal area and below the cell, at the apex, at the centre of the distal margin, and at the costal area of the forewing. Hindwing and body white. From the Lower Amazons. The two species differ also in many details of the genital armatures; *santiago* has a well developed scent-organ on the tegumen before the uncus, in *signata* it is absent.

As to the following purely white species we must consider that considerable differences in size may occur within the species, for instance the forewing may be from 6½ to 9 mm long, so that it might easily lead to mistakes, if we were to state the exact sizes of these pygmean species.

camela. **M. camela** Hopp, from South California, exhibits intensely glossy, somewhat prolonged forewings with transverse stripes.

filata. **M. filata** Hopp, from Bolivia, Colombia and the Amazons, is recognizable by long filiform sacculi which frequently project from the anal end.

gnathata. **M. gnathata** Hopp, from Peru and the Lower Amazons, has rather narrow wings and a broad arched gnathos.

cristata. **M. cristata** Hopp, from South Brazil, exhibits tufts of chitinized, narrowly lanceolate listels on the tegumen, presumably representing a scent-organ.

jasminata. **M. jasminata** Dogn. (= *tenuis* Hopp), from South Ecuador, Bolivia, and Peru. The wings show a slight greenish tint; the species is characterized by a hooked tapering uncus, very narrow long delicate harpes and likewise delicately chitinized sacculi with very broad ends.

nivea. **M. nivea** Hopp (= *sycophanta* Dogn.), from Bolivia and Peru. The clumsy curved uncus is dorsally set with spikes, the harpes are coherent by a high chitine-wall behind which the small club-shaped sacculi are situate.

hippopotama. **M. hippopotama** Hopp, from Costa Rica, Colombia, and the Amazons, has rather broad short wings, an almost straight uncus, double harpes, and hollow-shelled sacculi with tapering ends.

minuta. **M. minuta** Druce, from Panama and Colombia, resembles a small *Norape* in its habitus. The harpe is here a short pointed dent, the sacculus is terminally incurved, bicuspid.

simplex. **M. simplex** Hopp, from Peru, lacks the harpes, the sacculi are similar to those of *minuta*, but with one point.

M. shilluca Schaus, from South Brazil, which I have not seen, is described to have sacculi similar to *shilluca*, those of *Norape tosca*.

B. Forewing with 11 veins.

a) Antennae red.

The three genera comprised here have antennae from purple red to bluish-red, and white or partly red hair on the head. There are also some species of *Norape* with reddish antennae, but they can be recognized by the partly yellow hair on the head. Red hair do not occur in *Norape* nor does yellow colouring occur in the following genera.

5. Genus: **Proterocladia** Hopp.

Recognizable by the long anastomosis of the 1st radial branch of the forewing with the subcostal vein. Besides, *Proterocladia* is intermediary between *Aithorape* and *Hysterocladia*, the characters of which it unites. Only one species:

P. roseata Hopp (160 a). White, slightly greenish in fresh specimens, shoulder-angles red, head red as *roseata*, far as the frons. The red colouring of the antennae easily vanishes in specimens of collections. Costa of forewing beneath blackish from the base to beyond the middle. From Peru, Uberaba (Minas Geraës), and Matto Grosso.

6. Genus: **Aithorape** Hopp.

The species of this genus are much larger on an average than those of the *Hysterocladia*. They are externally discernible by the neurulation of the forewing: the third media and the first cubital vein are short-stalked in *Aithorape*, separated, however, in *Hysterocladia*. Moreover, they differ in the sexual armature: the uncus of *Aithorape* has a defined spike at its end, which is absent in *Hysterocladia*. The uncus-appendages (socii) are dorsally inserted in *Aithorape*, ventrally-basally, however, in *Hysterocladia*. All the species of *Aithorape* have harpes, while the *Hysterocladia* have only one species with even rudimentary harpes. Most of the species of *Aithorape* have a narrowly black-edged costa in the forewing, the ♀♀ are apparently without it.

The species of *Aithorape* are difficult to determine externally, as they look almost alike. But their male sexual armature shows constant extraordinary differences.

A. longanella Hopp has large harpes with broad ball-shaped ends, an anellus laterally ending in one *longanella*, long tip each, and very long transtilla-branches. Peru.

A. roseicornis Dogn. (= *bella* Druce) (160 a) has still longer harpes which, however, remain narrow, pointed *rosei-* to the ends and often project from the abdomen. This is the most widely distributed species. Costa Rica, *cornis*, Colombia, Ecuador, Peru, Bolivia, Upper Amazons.

A. flammicornis Schaus seems to differ with *roseicornis* geographically; it has been found in Trinidad, *flammi-* Guiana, Venezuela, and the Lower Amazons. Its harpes are shorter, but similarly structured as in *roseicornis*. *cornis*. Constant differences have been ascertained on the uncus and the transtilla-branches.

A. candelabaria Hopp has very long narrow falciform sacculi basally coherent with the shelled broad *cande-* short harpes. Peru. *labaria*.

A. spinulata has very broad, shelled harpes on the inside of which the small horn-shaped sacculi are *spinulata*, situate. Peru.

A. albicostata Hopp is without or almost without the fine black margin of the costa of the forewing. *albi-* The dorsal appendages of the uncus are longer than in *spinulata*, and without the large basal spike. Trinidad, *costata*. Lower Amazons, Minas Geraës, Paraguay.

A. frontalis Schaus, the northernmost species, has also a white costa of the forewing, white hair on the *frontalis*, head, the uncus-comb is reduced to a paired basal spike. Mexico and Guatemala.

A. analis Hopp (160 a) has the southernmost range. The uncus exhibits but faint traces of former spikes; *analis*, large, club-shaped sacculi and low, broad harpes; it has white hair on its head, and broad pectinate antennae. Sa. Catherina, also on the Itatiaya (Brazil).

7. Genus: **Hysterocladia** Felder.

The differences from *Aithorape* have been stated above. Many species exhibit besides more red colouring of the hair on the head, of the collar and thorax, but it is not always constant and, in spite of its conspi-

cuousness, it must not be used for determining the species except with caution. The genus is specially characterized by the lateral-basal appendages of the uncus, which are also often serviceable for the diagnose of the species, though it is not advisable to regard every difference of shape, of spikes of these appendages, slight differences in the shape of other male sexual parts as the characters of a species; they are either variable or caused by a changed position (which at once yields a very different projection), or they are effected by a preservatory treatment with a solution of caustic potash, alcohol and xylol. The determination of *Hysterocladia* is a task that cannot be solved satisfactorily without training and material.

- mirabilis.* **H. mirabilis** Schaus, from Colombia, is easily recognizable by the black costa of the forewing extending to the apex, and besides it is the largest species known (length of forewing: 15 mm) and therefore looks like an *Aithorape*. Vertex of head red. Anterior and middle legs blackish. Appendages of the uncus without the spikes.
- ferecostata.* **H. ferecostata** Hopp, from Peru, has also a black costa which, however, does not extend to the apex; it is a smaller species with narrower, somewhat prolonged forewings (11 mm long), and small roundish hindwings. Vertex of head red, slightly intermixed with white. The uncus-lobes terminate into a long thorn almost reaching the sacculi which are slender, ramified; the anellus is deeply sinuate with long lateral tips.
- primigenia.* **H. primigenia** Hopp, from Peru, is second in size (length of forewing: 13 mm); it has male sexual organs similar to those of *Proterocladia* and is therefore the only *Hysterocladia* with filiform rudimentary harpes ending in a hair-pencil and arising on huge, dark-chitinized hollow bases. The head of the only specimen at hand is coloured red between the base of the antenna and the eye.
- latiunca.* **H. latiunca** Hopp (160 a) is one of the smallest species (length of forewing: 9—9½ mm) and may be identical with *corallocera* Fldr. the specific character of which, however, is no more ascertainable from the figure of a ♀. The red hair-tuft of the thorax may also be absent. The uncus has broadly oviform wings. The sacculi twine round the anellus. Widely distributed: Cuba, Guiana, Amazons, Ecuador.
- roseicollis.* **H. roseicollis** Dogn. (160 a), as the name indicates, has a red collar, and besides red thoracal hair covered by the white tegulae; the vertex of the head is pink. The same red colour, however, is also found in *vicina* and *tolimensis*. The uncus has broad wings, narrowed apically; uncus-lobes roundish, the one pair with a long spike. Guiana, Upper Amazons.
- vicina.* **H. vicina** Hopp, described as a subspecies with transitions, differs in the narrow, prolonged one pair of uncus-lobes, and broader sacculi provided with knee-shaped hunches. Peru, Bolivia.
- tolimensis.* **H. tolimensis** Hopp has the same exterior and differs in short, scanty spikes of the appendages of the uncus, broad flat sacculi which are broadly turned over on the inside, and the deeply sinuately parted anellus with rounded terminal lobes. Colombia (Cañon del Tolima).
- servilis.* **H. servilis** Hopp is a rather large species (length of forewing: 12 mm) from Peru; the head is partly coloured red, the uncus is narrow, not winged, with large appendages, one pair of which terminates into a large spike. The sacculi are large, curved, intensely chitinized inside, the anellus deeply sunk.
- wernerii.* **H. wernerii** Hopp, from Colombia, is recognizable by the dense number of spikes on the end of one pair of the uncus-lobes; the sacculi are large, with lateral tips.
- elongata.* **H. elongata** Hopp is a large species (length of forewing: 13 mm), from Peru, with especially large prolonged uncus-lobes, one pair of which is apically set with several small spikes, with a narrow long uncus, large sacculi in the shape of broad hooks, the inside of which is intensely chitinized.
- lena.* **H. lena** Schaus exhibits the two pairs of uncus-appendages roundish, almost fused, the sacculi narrow, pointed, slightly curved. From Costa Rica, Venezuela, Guiana, the Amazons, and Colombia.
- ignicornis.* **H. ignicornis** Schs. is rather small with a winged uncus, the one pair of appendages are knee-shaped and irregularly spiked; the shape of the sacculi is somewhat variable, either broader or narrower small hooks, sometimes prolonged apically; middle legs blackened inside. Head white or partly red. This seems to be a characteristic representative of the tropical coasts, known from Panama, the western coast of Colombia, Guiana, and the Amazons.
- conjuncta.* **H. conjuncta** Hopp with red hair on the head was separated from it owing to the shortened transtilla-branches and the narrow uncus which is not winged. Ecuador and British Guiana.
- eriphua.* **H. eriphua** Dogn. is the only *Hysterocladia* with an apparently rudimentary marking or partial colouring on the forewings; brownish stripes between the veins are widened at the distal margin on the veins and fringe. Head white, with single red places around the antennae and on the vertex. Described as *Mamella*, but according to DYAR it belongs to this genus here. The species has remained unknown to me. Panama.

b) *Antennae colourless, ochre or black.*

8. Genus: **Coamorpha** Dyar.

The 1st radial branch (vein 11) of the forewing anastomoses here with the subcostal vein (12) as in *Proterocladia* from which it differs externally in the colourless antennae. Regarding the sexual armature of the ♂, the genus is isolated from the *Trosiinae* and resembles rather the *Megalopyginae*. The uncus is a curved smooth thorn. The socii are ventrally broadly connected with the rectum (scaphium). One species only:

C. innoxia Schaus (= *glutina* Schaus). Head and chest grey, mixed with white. Abdomen dark grey, *innoxia*, with some white hairs above. Forewing greyish-brown; a white spot at the base, a white streak below the cell, interrupted at veins 2 and 3, a white streak above the basal half of the inner margin, some white ones at the distal inner margin, at the outer half; fringe white with dark spots at the end of the veins, and faint, terminally white markings between the veins. Expanse of wings: 32 mm. Costa Rica. I have not seen the types which are in the Washington Museum.

9. Genus: **Norapella** Hopp.

The genus *Norapella* represents the most primary stage of development of the male 10th ventral segment in the *Trosiinae*. The tergite-appendages, uncus and socii are still paired here, and besides one species exhibits a paired gnathos as the appendage of the sternite. The species are uniformly white, rather small, with smooth forewings which exhibit a black costal streak beneath, and light antennae.

N. bipennis Hopp (160 b). The ♂ has an expanse of $11\frac{1}{2}$ to $13\frac{1}{2}$ mm and differs from the other species *bipennis*, in the 1st cubital vein and 3rd median vein (veins 3—4) of the hindwing being short-stalked instead of separated. The paired uncus-hooks are distantly separated from each other, whereas they are close together in the other species. Socii slender, appendent only to the extreme base of the uncus-thorns, extending into the interior of the 10th segment; a paired gnathos, chitinized blackish-brown, outside granular, globular, but smooth and somewhat concave inside. The harpes are very small, delicate, hairy, near the 10th segment. The sacculi are large, apically on one side pinnate by lineary lancet-shaped chitine-bristles, presumably distributing scent. Taperinha near Santarem, Amazons, discovered by ZERNY (Vienna).

N. rhadina Dogn. (= *fassli* Hopp), described as a *Trosia*. The ♂ (expanse: 20—22 mm) has also the *rhadina*, uncus-thorns divided as far as the base, but they are close together. The socii are fused laterally with the uncus-thorns on half their length, their continuation reaching the length of the uncus-thorns. Pacho near Muzo, Colombia.

N. gracilis Dogn. (described as *Archylus*) is similar to *rhadina*, of about the same size, with broad, basally *gracilis*, coalescent socii from the interior sides of which the intensely chitinized uncus-thorns arise; the lateral lobes of the socii are feebly chitinized. Peru, Bolivia.

N. parva Schaus (described as *Trosia*). The ♂ (expanse: 17—20 mm) chiefly differs from *rhadina* in *parva*, the lateral tips of the socii-lobes being intensely chitinized at their ends. South Brazil.

10. Genus: **Cephalocladia** Hopp.

Cephalocladia is characterized by a peculiar structure of the 10th male ventral segment. The latter consists of a roundish massive, slender, somewhat curved staff at the end of which there is a broader, roundish, dark-chitinized head which is bivalvular on its ventral side. On the right and left sides of this uncus composed of staff and head, there is rectangularly to the uncus, one flat chitine-listel each, the socii. The species have the same exterior as *Norapella* and are externally hardly discernible from each other.

C. weneri Hopp is purely white, forewing without stripes, veins faintly white. The sacculi are flat, *weneri*, intensely chitinized, dentiformly bent over inwards at the end, widened basally. From the Rio Caqueta, South Colombia.

C. mossi Hopp differs in shorter (longer in *weneri*) valves of the uncus-head, shorter and broader socii, *mossi*, and much larger and broader harpes. Pará (Brazil) and Guiana.

C. fulvicornis Dogn. (described as a *Hysterocladia*) of which I only know the photograph of the male *fulvicornis*, sexual armature has falciformly curved slender sacculi. From the Upper Amazons.

11. Genus: **Mesoscia** Hbn.

The genus *Mesoscia* Hbn. (*Saltiga* Wkr., *Archylus* Wkr., *Ramaca* Dyar) is characterized by the appendages of the male 10th ventral segment being represented by an unpaired uncus and lateral paired socii or by the socii being laterally fused with the uncus. From this organization differ: *Malmella* in which the uncus projects as a dorsal comb beyond the ventrally fused socii, *Macara* and *Trosia* the fused socii of which are likewise situate ventrally to the uncus, and *Norape* in the species of which the uncus is absent or only rudimentary. In contrast with the compared genera, *Mesoscia* observes a more original stage in this respect. Correspondingly also most of its species exhibit yet colourings and markings which *Malmella*, *Macara*, and *Norape* have lost or which are only rudimentary in them. But also single *Mesoscia* show already the loss of pigment. Most of the *Mesoscia* exhibit the median branches 2 and 3 (veins 4 and 5) on a long stalk, but this mark varies individually and occurs also in single specimens of other genera. The species are not only discernible by the male sexual armature, but mostly also by their colourings and markings.

- pusilla*. **M. pusilla** Stoll (= *latifera* Wkr.) (160 b). The brown distal margin of the forewing is pierced here by white veins. Collar pink or white. Hindwing with a more or less large white central spot. Guiana, Panama, Colombia, Amazons to Peru.
- dumilla*. **M. dumilla** Dyar (160 b) is the Mexican representative of this species, the brown distal-marginal zone of the forewing is smaller, the brown median band at the inner margin still broader, the collar invariably white, hindwing almost white. The male sexual armatures of both the species are distinctly separated; *pusilla* is especially characterized by a longer casing of the penis-mantle and a broad-shelled anellus.
- dyari*. **M. dyari** Schs. is distinguishable by the strongly reduced white postmedian band of the forewing. Costa Rica.
- pascora*. **M. pascora** Schaus (160 b). Here all the brown of the forewing and hindwing is more grey and besides interrupted by white veins. South Brazil.
- procera*. **M. procera** Hopp (160 b) with a pink or white collar shows the brown distal margin of the forewing and hindwing broken up into wedge-shaped brown stripes between the veins; this species has very long sacculi which are bare like the harpes, but hairy in *pusilla*. From the Amazons.
- eriphora*. **M. eriphora** Scpp (= *antonina* Dogn.) (160 b) is very similar to *procera* in the wedge-shaped brown stripes at the distal margins of the wings, but it is larger, and the brown median band of the forewing is hardly widened at the inner margin; it lacks the white belt at the base of the thoracic dorsum. Guiana, Panama, West Colombia.
- anguilinea*. **M. anguilinea** Schs. (= *inflexa* Hopp) (160 b). The white postmedian band of the forewing is almost rectangularly incurved, it ends pointedly near the subcostal vein. The sizes of the ♂♂ differ here from 15 to 23 mm, and besides there occur specimens with entirely white hindwings. Guiana, Amazons, South Colombia (Moeoa).
- terminata*. **M. terminata** Schs. (= *fluxa* Schs., *meroma* Drc.) (160 b). This species as well as
- lorna*. **M. lorna** Schs. (160 h) are so characteristically coloured and marked that we may refer to the figures. Both the species are widely distributed, *lorna* from Mexico downwards, *terminata* from Costa Rica downwards, in Guiana, Venezuela, Colombia, Ecuador, on the Amazons from Para to Peru, but they are absent in South Brazil.
- itatiayae*. **M. itatiayae** Hopp is all white with a narrow black costa of the forewing, and black tibiae and tarsi. In the structure of the male 10th ventral segment it is relatively near *M. lorna*, but very different from the externally rather similar *N. beggoides* Dyar with which it occurs on the Itatiaya. On an average, *itatiayae* is the smaller species with somewhat narrower forewings. Fresh specimens show that *itatiayae* has a dorsal light yellow hair-tuft as the base of the abdomen, while in *beggoides* the whole abdomen is suffused with yellowish. If the curved sacculi project from the abdominal end, the species are discernible by the sacculi being gradually pointed in *itatiayae*, distinctly defined in *beggoides*.
- guttifascia*. **M. guttifascia** Wkr. (160 b) (described as an *Archylus*) is a white species with black feet, the forewing marked with black streaks and dots. Amazons, Guiana, Colombia.
- unifascia*. **M. unifascia** Dogn. (160 b) differs from *guttifascia* in the smaller number and size of the black spots and especially in the shorter socii of the males. Known from Costa Rica and Panama; described and figured as *guttifascia* in the Biologia Centrali-Americana.

12. Genus: **Trosia** Hbn.

Trosia Hbn. (*Sarothroma* H. Sch., *Sciathos*, *Edebessa* Wkr., *Endobrachys*, *Isochroma* Fld., *Alimera* Möschl., *Langueys* Butl., *Thoscara* Schs.) is characterized by the little pigeon shape of the appendage of the 10th male ventral segment, produced by the coalescence of the uncus with the socii into an azygous body, covered by a thin skin with a structure of tactile hollows, only the extreme end being sometimes bare. As in the 13th genus *Macara*, the socii are situate ventrally to the uncus. Brightly coloured species which are only rarely white owing to a loss of the pigment, often with characteristic markings. But the colourings and markings frequently form transitions to each other, and the species are partly more closely allied than in other genera. For the usual distinctive mark of the ♂♂, the shape of the sexual armature, is not always suitable here for determining the species. Only few species can be safely separated in this way; the organization of the sexual armature is the same in nearly all the species, and smaller differences in the shape of the stout or slender uncus, of the glandular-lobate, hairy sacculi, the shelled slender harpes, the cornuti etc., prove to be inconstant. Besides some species exhibit a great variability of size, colouring and marking, though they are not exactly races. Extreme forms appear to be confined to certain localities, but the same tendency of variation occurs in distantly remote parts of Central and South America. The way the colourings have developed as pigmenting stages can often be recognized: black is replaced by red, red by orange, orange by yellow, yellow fades into white. On the other hand, however, also dark brown pigments occur as new formations, and besides reddish ochreous pigments are covered by black owing to certain climatic conditions (in alpine districts or rainy forests). Also other morphological details, such as the length of the hair, the wing-contours, are only average distinctive marks for the species. Distinct morphological differences between the real species, as far as they have been explored, are present in the female genitals, but they cannot yet be described to-day, especially since the ♀♀ of many species and forms are not yet known.

1. *Edebessa*-group.

In many respects the *Edebessa*-species are the most generalized of the genus. They are relatively large and show especially bright colours and markings. The 10th male ventral segment is broader and flatter than in the other species and sometimes exhibits yet dorsally at the end a middle seam as a rudiment of former pairedness.

T. nigropuncta Drc. (160 c) unites on the wings the markings of the other species of the group, but it seems to be little variable. It has a black abdomen, a red mesothorax, a black prothorax and head, and black legs. All the black is more or less dusted over with leaden grey. The width of the forewings is rather variable. Peru, Ecuador, Colombia. *nigropuncta*.

T. nigrorufa Wkr. (= *obusta* Dogn.) (160 c) has a black head, thorax and 1st ventral segment, dusted with leaden grey, a light vermilion abdomen, black legs, sometimes with small white or red parts. The marking of the wings is variable; the large black parts are broken up into smaller spots and streaks, the red places become ring-shaped or moon-shaped. Extreme such forms are: *nigrorufa*.

T. bicolor Mschl. (= *languciata* Schs.) (160 c) both in the ♂ and ♀. *nigrorufa* and its transitions are known from Peru, Ecuador, Colombia, the Amazons and Guiana, *bicolor* hitherto only from Guiana. *bicolor*.

T. circumcincta Schs. (160 d) has a black head, thorax and 1st abdominal segment dusted with leaden grey, the rest of the abdomen is light vermilion above, black beneath. Femora and tibiae outside red, inside black, tarsi red. These marks are noteworthy, especially for the distinction of the ♀♀ of *circumcincta* and *purens*, which are otherwise sometimes very similar. — **purens** Wkr. (160 d) has a red head and thorax, the prothorax with a dorsal saddle which is dusted with whitish grey, similar lateral spots on the mesothorax and a dorsal one on the metathorax. The legs are red, with scanty whitish hairs. Abdomen red also beneath; also the 1st ventral segment is red above. *circumcincta* is hitherto only known from Guiana, *purens* from Rio de Janeiro, Minas Geraës, Paraguay, the Lower Amazons, and Guiana. *circumcincta*. *purens*.

2. *Revocans*-group.

T. revocans Fldr. (160 d) (described as *Endobrachys*) is allied to the *dimas*-group in spite of the different scheme of markings; its male sexual armature can be hardly distinguished from that group. The name is due to a figure of the ♀ from French Guiana, by which KIRBY was induced to regard the species as a *Notodontida*, Synonymous are *jeanette* Dyar from French Guiana and *arpi* Schs. (*ferugina* Jones) from Rio de Janeiro; the differences of colour, according to which the latter were named, vary individually, though in South Brazil the yellow tints may be more common and the grey tints of the hindwings frequently more reduced than in *revocans*.

Guiana. The type of *ferugina* shows a pink thorax with a magnificent gloss, whereas otherwise the thorax *caramia*. mostly exhibits only smaller pink or white spots. — **caramia** Dyar (160 d), from Peru, is an orange-red variety which, however, forms transitions to *revocans* everywhere on the Amazons. In all kinds of colourings *revocans* is distributed from Peru down the Amazons to Para, in Guiana, Paraguay, Minas Geraës, and South Brazil.

pulchella. **T. pulchella** Schs. (160 d) is very closely allied to *revocans* and likewise variable in the colouring. It is recognizable by 1 or 2 small black longitudinal streaks in the anterior part of the cell of the forewing. Besides it is still more variable in colours than *revocans*. Purely yellow specimens from Peru pass over to dark grey ones on the Amazons, and the grey colouring may also extend to the abdomen. The yellow colouring may change to deep orange-red, the pink parts of the thorax may also pass over to the wings, and the wing-contours vary so much that the forms become quite similar to *dimas* Cr. The species is absent in South Brazil.

placida. **T. placida** Jones (160 c), however, is almost constant in its colouring and marking; its range seems to be confined to the Corcovado and Itatiaya near Rio de Janeiro. Vertex of the head, femora and thorax orange, the latter with a pink or white belt-zone, the costa of the forewing, the abdomen, tibiae and tarsi are deep black, the tarsi pointed with white hairs. Forewing broadly edged with yellow subcostally and on the long inner margin, otherwise greyish-black like the hindwing. A narrow orange belt near the base of the abdomen.

3. *Acca*-group.

acca-acca. **T. acca** Schaus (160 e) with its geographical races is distinctly defined from all the species by the harpes of the male sexual armature exhibiting near the apex a broad short lateral excrescence which is absent in the other species of *Trosia*. In — **acca-acca** Schs. the abdomen and hindwings are yellowish ochreous, the blurred *ribbei*. dark transverse band of the forewing is more distinctly marked, in — **ribbei** Drc. (160 e) the abdomen and hindwing are reddish ochreous, the transverse band of the forewing indistinct or absent. These differences occur in both genera. *acca-acca* is known from South Brazil (Espírito Santo to Santa Catharina) and Paraguay; *electra* Hopp, from Paraguay, founded upon small differences in the shape of the sacculi, is synonymous, as these differences are not constant; *ribbei* is widely distributed, in Bahia, on the Amazons as far as Peru, Guiana, Venezuela, Colombia, Panama to Mexico. Transitions of the two races are found on the eastern slopes of the Andes in Colombia, Ecuador, Peru, and Bolivia. The brightest red specimens of *ribbei* became known from Costa Rica, while specimens from Mexico, Guiana and Bahia are again more yellowish ochreous. Another race *aterrima*. — **aterrima** Hopp (160 e) is a descendant of *ribbei* owing to the reddish ochreous head, thorax and femora, with blackish-grey to deep black tibiae, tarsi, wings and abdomen a product of the intensely rainy forests on the western coast of Colombia.

The following species exhibit normal branchless harpes. They resemble *acca* only in their colouring.

ochracea. **T. ochracea** Hopp (160 e) is very similar to *acca*. Only the type from Rio de Janeiro is at hand. Forewing and thorax are lighter and more grey, hindwing and abdomen more yellowish ochreous, the hair smoother, longer and more scanty.

The two following species represent transitions from *acca* to the *dimas*-group in their colouring and marking.

rufa. **T. rufa** Jones (160 e). Both sexes with rather dark brown, thinly scaled forewings exhibiting a reddish shine produced by single red hairs. The wing is crossed, from the costa to the inner margin, by a band of black, thinly scaled spots which spread widely on the costal half of the wing and become indistinct thereby. Head brown, frons red. Thorax brown, abdomen red, anus light brown. Anterior legs with short black hair on one side, with long red hair on the other side, the other legs red and light brown. South-Eastern Brazil: Alto da Serra (São Paulo), Corcovada and Itatiaya near Rio de Janeiro.

rubrivena. **T. rubrivena** Jones (160 f) has almost the reverse colouring: forewing red, thinly scaled, with a light brown shine produced by brown hairs. The transverse band of black spots through the wing as in *rufa*. Head red, frons brown or red. Hindwing reddish, likewise thinly scaled. Thorax red, suffused with light brown. Abdomen red. Legs red or partly light brown. Brazil: Castro (Paraná) and Matto-Grosso.

pellucida. **T. pellucida** Mschlr. (*Chrysopyga*) (= [*Thoscora*] *brugea* Schs., [*Podalia*] *darca* Dyar) (160 f) is a species that has frequently been misinterpreted owing to the original description of the ♀. The ♂ has dark brown forewings which are densely scaled and show somewhat darker veins. Hindwing somewhat lighter, with a streak of dark hair near the anal margin. Thorax dark brown above, ochreous beneath like the head, legs and anus. The abdomen has double hair, the lower being dark brown, the upper ochreous. The ♀ is more thinly scaled on the wings, but of the same colouring. Guiana, Venezuela, Colombia (Eastern Cordilleras and western coast).

T. brucea Schs. (Thoscora) (160 l) which has been placed as a synonym to *pellucida* must probably be *brucea*. regarded as a distinct species. Both the sexes differ from *pellucida* in longer, uniformly ochreous hair on the abdomen, the ♂ also in ochreous hair on the anal margin of the hindwing. Venezuela, Guiana, Pará.

T. xinga Dogn. (described as *Podalia*), from the Rio Xingu (Amazons), which I only know from the *zinga*. description, has pale blackish-brown wings and fringes, the abdominal margin of the hindwing is covered with long reddish hair like the abdomen. The latter, the head, and the coxae (presumably the femora) are reddish, the tarsi of the first pair of legs covered with long blackish hair. Thorax slightly brownish.

T. zikáni Hopp (160 l), from Minas Geraës (Brazil), is allied to this species and may be only a differ- *zikáni*. ently coloured form of it with light grey scales which are more intensely brown only on the base of the wing, the costa of the forewing and on the veins. Head orange-brown, thorax dark brown, abdomen intensely orange-red, with a yellow annus. Hindwing with orange-red hair at the anal margin. Femora orange-red, tibiae yellowish-grey, tarsi brown. The orange-red colouring is replaced by ochre in some specimens.

T. omayena Schs. (160 l), described as *Gerontia*, but placed to *Podalia* by DYAR, in fact looks like a *omayena*. *Podalia*, especially since it is the only *Trosia* exhibiting white antennal shafts. Yet it undoubtedly belongs to *Trosia* owing to the 10th ventral segment of the ♂. Head, thorax, and forewing pale greyish-brown, the forewing with prominently dark veins. Abdomen and hindwing, as well as the thorax beneath and the femora are more yellowish-brown, especially at the anal margin of the hindwing. In the ♀ the thorax and the hair of the legs are partly more dark brown, but partly also nearly whitish. British and Dutch Guiana.

4. *Dimas-punctigera* Group.

T. dimas Cr. (= *tricolora* Fabr.) (160 f). *dimas* and *punctigera* exhibit the transverse row of spots on the forewing, traces of which were already discernible in *rufa* and *rubrivena*. They are two common closely allied species of almost the same wide range: Mexico to South Brazil. *dimas* is generally the smaller species; the ♂ has broader shorter forewings, a more narrowly coloured costa, longer looser hair, a shorter and broader uncus. *punctigera*-♂ has an expanse varying between 40 and 27 mm, *dimas*-♂ between 39 and 20 mm. One of the most distinct differences is the number of the spots of the transverse band through the forewing: 8 in *dimas*, 7 in *punctigera* which almost invariably lacks the costal spot owing to the broader red costa.

T. dimas Cr. CRAMER's figure of it is a failure, the habitat stated to be the "West Indies" is doubtful, *dimas*. as the species occurs in Trinidad, but not in the West Indies. The usual colouring is: head and its surroundings red or mixed with white, thorax white, with 6 red spots, abdomen red, beneath and at the anus white, femora red, beneath white, tibiae and tarsi black, interrupted by white, the tibiae with longer hair. Forewing white, or feebly pink owing to the under surface showing through, costa red or orange, the transverse row of spots black, under surface red or partly white; hindwing above and beneath red with white fringe. Besides this most common colouring there occur all kinds of chromatic deviations excepting the tibiae and tarsi which seem to be invariably black and white. The other parts of the body vary in red, yellow, white, and brown colours, and the red colour may vary from an intense carmine to a pale pink and may also pass over into yellowish-red tints; yellow occurs in all stages between dark ochre and white. The chief colourings are: thorax white, yellow, red, brown, thoracal spots red, yellow, white, forewing above white, yellow, brown, red, costa of forewing red, white, yellow, forewing beneath red, red partly with white or yellow, entirely white or yellow, abdomen red, yellow, white. The fringes of the wings are sometimes also partly of different colours: red, black, yellow, white. Femora red, yellow, or white. When combining only the more common ones of these colourings we discover more than 486 differently coloured forms, of which surely a great part occurs in nature. Besides, however, there are also varieties in the marking. Thus the forewing sometimes exhibit longitudinal rays of other colours such as white, brown, yellow, and a smoky brown coat which is narrow in the basal area and extends over a more or less great part of the forewing. Such forms may be called — **fumosa** (160 f); ZIKAN collected of a *fumosa*-form quite a *fumosa*. number of transitions to the normal form, occurring from a slight smoky brown tinge to entirely dark brown forewings and to a dark brown instead of red thorax. Other similar forms of *fumosa* are also known from Costa Rica, Colombia, Peru, and Bolivia, they occur also on a yellowish ground-colour of the forewing. The transverse band of black spots through the forewing is also variable. It is elongate, curved once or twice, single or all the spots widened or strigiform; Mexican specimens showed also much smaller spots. — Only few of these many varieties, and by no means the extremest colourings, have been denominated. One may, however, use the existing names in order to classify the variations at least to some extent: — **flava**-forms (*flava* Dogn., in- *flava*. *costata* Schs. [160 f], *tolimata* Dogn. [160 f], *misda* Dyar, *amarilla* Hopp [160 f], — **albida**-forms (*albida* Dogn. *albida*.

rosita. [160 g]. (= *metaleuca* Drc. with *donckieri* Dogn., *obsolescens* Dyar) and — **rosita**-forms (*rosita* Schs.) (160 g); quite red-coloured forms, as we have figured one, are extremely rare. A melanistic aberration of *dimas*, which
nigra. may be named — ab. *nigra* (160 l), is deep black in all its parts, but the forewing exhibits yet the transverse row of spots. From Peru (Tring Museum).

punctigera. **T. punctigera** Stoll (160 g) is less variable, the *flava*- and *rosita*-forms of *dimas* have not been observed here. The distal-marginal area of the white forewing usually exhibits a more or less intense tinge of smoky brown which may be narrower or broader, so that the fringes appear to be interrupted white; sometimes, however, they are also blackened. The generally rather broad red costa of the forewing is followed by a white precostal streak. Forewing beneath red with the precostal white streak, but sometimes also entirely white. Hindwing mostly quite red, sometimes white at the base (form *amala* Dyar which, however, is by no means confined to Mexico). The transverse band of black spots through the forewing shows irregularities only of the inner-marginal spot which may be of a red colour and removed more distally. The abdomen of *punctigera* is generally
anax. red also beneath, being another mark of distinction from *dimas*. A particularly white-coloured form is — **anax** Dogn. (160 g) exhibiting white forewings with a red costa, and white hindwings with sometimes red-edged distal margins, while the abdomen beneath and the anus are white. This form is hitherto known only from Villavicencio (Colombian Eastern Cordilleras).

roseipuncta. **T. roseipuncta** Drc. (160 g) is a normally coloured *dimas* from which it differs only in the red, instead of black, spots of the band on the forewing, in the absence of other chromatic forms and in its being confined to South-East Peru.

fallax. **T. fallax** Fldr. (160 g). The transverse band of black spots through the forewing lacks the third dot (counted from the costa). The species is apparently constant in its colouring and marking, but the forewing, excepting the red costa, is rather uniformly greyish-pink distinctly contrasted by the white fringe, just as on the red hindwing. The tibiae and tarsi are covered with long white hair on one side. On the Rio Micay (Colombia), WERNER HOPP observed the species coming to the light about two hours earlier than *punctigera*, at 10 p. m. Costa Rica, Panama, Colombia, Ecuador.

semirufa. **T. semirufa** Drc. (160 g) resembles *punctigera* in the habitus. Forewing brown excepting the white costal stripe which is narrowly red outside. The transverse row of black spots through the forewing is absent or rarely rudimentarily represented by single dots. Peru, Bolivia.

zernyi. **T. zernyi** Hopp (160 g) is quite isolated among the *Trosia*. The neuration is also different, since the 2nd and 3rd medial veins (veins 4 and 5) of the forewing and the 1st cubital vein and 3rd medial vein (3 and 4) are on a short stalk instead of being separated. Judging from the shape of the 10th abdominal segment, however, the species belongs to *Trosia*. The 9th abdominal segment of the ♂ shows very long, strongly curved sacculi; the penis-case rests on a high support of the tegumen and is far away from the base of the sacculi, but near the harps. Completely dark greyish-brown with a darkened costa of the forewing and somewhat lighter fringe. Expanse of ♂: 15 mm. The short black antennae are broadly pinnate. Amazons: Taperinha near Manaus.

13. Genus: **Macara** Dogn.

The nomenclature of the genus is strangely confused. *Macara* owes its name to an individual anomaly of the veins sometimes occurring in these species in the way described and otherwise. The generic type *argentea* Dgn. however, proves to be synonymous to *argentea* Drc. (*Carama*) which DYAR placed first to *Norape*, later to *Trosia*. Besides there was yet a genus *Sulychra* Butl. But the attempt of uniting the *Macara*-species with this genus was frustrated by the generic type *argentea* Butl. being an artefact, i. e. the ♀ of *Norape argyrorrhoea* Hbn. (= *Carama pura* Butl.) with male antennae glued on. Moreover, *pasaleuca* Maass. was placed to the *hymantriidae* (*Leucoma*) by the author, to *Mesoscia* Hbn. by DYAR, and its synonyms *verditincta* and *niveitincta* Dogn. to *Mesoscia*. Furthermore, *purens* Schs. and *nigripes* Dyar were described as *Trosia*, *dyari* Dogn. as *Malmella*, *terena* Dogn. as *Mesoscia*.

In *Macara*, the appendage of the 10th male ventral segment is azygous and represents a roundish, massive, less chitinized "ventrum" bearing dorsally near the end a strongly chitinized small pointed hook or clasp-thorn; the latter extends distally as far as the "ventrum". Nearly all the species have light, relatively long antennae, white wings with a black costa of the forewing; the yellow colouring of the head and abdomen occurring in many white species of *Norape* is absent here.

argentea. **M. argentea** Drc. (*argentea* Dogn.) (160 h) is recognizable by the broad silvery transverse stripes on the forewing, similar to the Lymantriid genus *Caviria*. Costa of forewing white, legs black, partly covered with white hair. Costa Rica, Panama, Colombia, British Guiana, Ecuador, Peru.

nigripes. **M. nigripes** Dyar has likewise a white costa on the forewing which is less glossy, as it only shows a single

short transverse stripe. Tibiae and tarsi black. The thorn of the uncus is straight, slender. British and French Guiana, Pará, Trinidad, also from the Upper Amazons.

M. pasaleuca *Maass.* (= *verditincta*, *niveitincta* *Dogn.*) (160 h) is white, with hardly any gloss and *pasaleuca*. stripe, thinly scaled, the costa of the forewing narrowly black. Much flown specimens are feebly greenish, the black costa is then indistinct. West Colombia.

M. purens *Schs.* (= *mataca* *Schaus*) (160 h) is smaller, with narrower forewings and a distinct black *purens*. costa. Middle and hind legs black, covered with white. Described from French Guiana, the specimen figured from South Brazil.

M. heinrichi *Hopp.* The white forewing likewise without any transverse stripes, though fresh specimens *heinrichi*. exhibit longitudinal stripes of the forewing between the veins, by which the wings become very lustrous. Costa of forewing white, finely black at the base at most. Legs blackish. The uncus-thorn of this species is short and thick, curved. Peru, Ecuador, West Colombia.

The following two species I know only from the descriptions and a photo of the male sexual armature.

M. terena *Dogn.* has lustrous white wings. The forewing is a little prolonged at the apex, with a fine *terena*. black costa on the basal half. Middle and hind legs white. The photo of the male sexual armature shows sacculi with a narrow stalk and an almost spoon-shaped terminal part, feebly chitinized and ciliated. Tolima (Colombia).

M. dyari *Dogn.*, according to the description, has a reddish-yellow head, thorax and forewing, the latter *dyari*. with a postmedian row of black streaks from the middle of the inner margin to vein 7; hindwing pale reddish-yellow. Bogota (Colombia). The colouring and marking of this species seems to form a transition to *Trosia*; the close relationship of the two genera is probable owing to the condition of the male 10th abdominal segment.

14. Genus: **Malmella** *Dogn.*

According to the organization of the male 10th ventral segment, the genus ranges between *Mesoscia* and *Norape*. It has an unpaired uncus with which the socii are ventrally entirely grown together, from which only a dorsally apical comb of smooth chitine projects, breaking off sharply towards the ventral side. The uncus which is thus distinctly isolated prevents the species from being placed to *Norape*, and the ventral coalescence of the socii from being united with *Mesoscia*. The genus is not discernible by external marks, the length of the antennae and peculiarities of the neurulation upon which it was established do not prove to be constant. Thus also one of the four species originally described as *Malmella* belongs to *Norape*, one to *Macara*, and one to *Hysterocladia*.

M. strigiprima *Dogn.* (160 h), the generic type, is a small species with long antennae, the dingy white *strigiprima*. forewing is covered with brownish hair on the costa and all the veins, the vertex, dorsal abdomen and hindwing are white, the legs feebly brownish. From Tolima in Colombia.

M. nigricollis *Hopp* (160 h) looks like a *Norape*, as the white species exhibits transversely striped and *nigricollis*. thereby glossy silvery forewings and a yellow vertex; the tufts around the antennal base, however, are white. The collar is broadly blackish-brown, but this occurs also occasionally in species of *Norape*. Abdomen without yellow colouring, purely white. Middle and hind legs purely white. Peru and Ecuador.

15. Genus: **Repnoa** *Dyar.*

Repnoa *Dyar* (*Praenorape* *Hopp*) shows the appendages of the male 10th ventral segment paired; they consist of two slipper-shaped, hollow pouches which are delicately chitinized and set with touch-cilia; they do not represent the real uncus which has been lost or is rudimentarily represented by a very tiny chitine-staff, but the socii. *Norape* also lacks the real uncus, but the socii replacing it are never paired. — The species *dimidiata* *Wkr.*, *arpi*, *thanatos*, *amarga* *Schs.*, *cinninata* and *fuscoapicata* *Dogn.*, which were placed to this genus in the older literature, are *Megalopyginae*. Only 1 species:

R. imparilis *Schs.* (= *amazonica* *Dogn.*) (160 h). Only the ♂ is known. Vertex yellow, antennae basally *imparilis*. white. Thorax white with little grey. Abdomen yellow at the base and anus, the rest greyish-brown above. Middle and hind legs white. Forewing white, especially the cell and costa; all the veins with lines of brown hair. Hindwing also white, the brown lines of the veins narrower. British Guiana, Amazons, East Colombia. — **alba** *Hopp* (160 h) lacks the brown lines on the veins and the brown colouring of the abdominal dorsum, *alba*. but it has no other differences. The white form is known from British Guiana, the Lower Amazons, Espiritu

Santo, Paraguay, and the Itatiaya (Brazil). ZERNY captured both the forms at the same time on the Lower Amazons.

16. Genus: **Norape** Wkr.

Norape Wkr. (*Mallotodesma* Wall., *Ulosota* Grt., *Sulychra* Bltr., *Anarchylus* Dyar) is characterized with the 10th male abdominal segment by the absence of the real uncus, or it may be quite rudimentary, while the socii are unpaired, grown together, mostly representing a flat, glandular, partly ciliated small chitine-leaf. In some cases this organisation is not to be recognized directly; thus the formation is indistinctly paired at the end in *incolorata*, or it shows lateral paired lobes in *puella*, *nigrovenosa*, *albilineata*, *glabra*, *pampana*, which are thus probably closely allied, or it is massive and conglobate at the end in *cingulata* and *vesta*, or long, cylindrical in *rothschildi* which shows an interesting adaptation: the socii being originally feeling organs replace here the uncus which operates as a clasp-hook.

The colourings and markings of the *Norape*-species are probably always to be regarded as rudimentary, as they coincide with a relatively more original structure of the 10th male ventral segment. The pigments are at any rate no reliable marks of distinction for a species of the *Trosiinae*, and in this respect also a great number of *Norape*-species, which can be distinctly determined by the male sexual armature, are inclined to variations.

For purposes of discrimination, we have divided the *Norape*-species according to their pigment-colourings. However, some species exhibit variably coloured wings, while in others the yellow colouring of the head and abdomen vary, and black-legged species partly occur also with white legs. When speaking of white or black legs, this always refers to the middle and hind legs, as the forelegs are invariably blackened on their insides.

A. Species recognizable by pigments of the wings:

- incolorata*. **N. incolorata** Jones (160 i). Greyish-brown, all the parts rather intensely tinged, especially on the costal area of the forewing. Forewing smooth, without stripes. A rare species from Castro, Paraná (Brazil).
- mexicana*. **N. mexicana** Schs. (*Archylus*, *Anarchylus*) (160 i). White, forewing with a black dot at the end of the cell and at the end of the inner-marginal vein. Antennae long, light. Mexico.
- cana*. **N. cana** Dogn. (*Sciathos*, *Trosia*) (160 i) is hitherto known only from the environs of Bogotá in Colombia, where it occurs in three transitory chromatic forms: silvery white with a grey shine, or distinctly grey, or more
- flavescens*. or less suffused with lemon colour. The latter form has been described as — **flavescens** Dogn. (*Malmella*) (160 i). The forewing shows a fine black costa. Tibiae and tarsi black. Vertex of head yellow. Abdomen suffused with yellow. Collar whitish or yellow, anteriorly edged with black. The antennae of the males vary in length, especially also in the width of the pinnae. The neuration of the wings varies in some respects.
- dyarensis*. **N. dyarensis** Hopp (nec *terena* Dogn.). Only 1 specimen is at hand, from Mt. Tolima (Colombia). Forewing scantily scaled, distinctly striped and with a bright silvery gloss, white, tinged with brownish, the hindwing more whitish. Head, thorax, abdomen, legs white.
- tenera*. **N. tenera** Drc. (= *Archylus tener* Drc., *Ramaca achriogelos* Dyar) (160 i) is distinctly marked, forewing with hardly noticeable stripes. Collar blackish, sometimes also white. Thorax white or blackish, metathorax mostly black. Abdomen without yellow colouring. All the tarsi blackish. The neuration of the wings varies in some respects. Mexico and Arizona.
- laticosta*. **N. laticosta** Dyar (160 i) is white, with a broad black costa of the forewing, and likewise very feebly striped, without a silvery gloss. Head yellowish around the antennae, vertex white. Collar white, more rarely narrowly blackish. Abdomen purely white, without yellow. Tibiae and tarsi blackish. The species is closely
- eutecta*. allied with *tenera* owing to the male sexual armature. Mexico. — **eutecta** Dyar (*Mesoscia*) (160 k) is only a pigment-form of *laticosta* flying at the same time (June) and places in Mexico; the sexual armature is the same, the neuration of the wings varies in the same way, and the head is also yellowish around the antennae, the vertex white. Tibiae and tarsi blackish.
- puella*. **N. puella** Wkr. (= *pectoralis* Wkr.) (160 k) is the type of the genus. Characterized by fine black areas between the veins of the otherwise white, transversely striped, glossy forewings. Vertex yellow, though with white basal tufts around the antennae. Abdomen white, middle and hind legs white. South-East Brazil, for instance Rio de Janeiro, Itatiaya, Sa. Catharina, Paraná, Esp. Santo.

N. venata Schs. (160 k) is very closely allied to *puella*, but distinguished in the male sexual armature *venata*. by half as long harps and, externally, by prolonged black areas between the veins at the inner margin of the forewing. The species is larger, on an average, than *puella*. South-East Brazil, rarer than *puella*.

N. undulata Jones (160 k) does not differ from *venata* in the male sexual armature, but it is differently *undulata*. marked; a small single or double streak in the end of the cell, a subterminal row of blackish, roundish-square spots; basal third of costa beneath blackish. Hindwing purely white. Forewing with transverse stripes. Vertex and basal tufts of antennae white, whilst the vertex is yellow in *venata* and *puella*. A rare species from Paraná, Sao Paulo, and Minas Geraës (Brazil).

N. jaromillo Dogn. (160 k) is likewise near to *puella*, as the male sexual armature shows. Forewing *jaromillo*. dingy white, studded with brownish scales, and with a central straight blackish line proceeding from the base and disappearing beyond the centre of the wing. Abdomen and legs light brown. Loja, Ecuador.

N. miasma Dyar is brownish white in all its parts, but individually of variably intense tints, especially *miasma*. on the forewing beneath the costal area of which is sometimes intensely dark brown. Legs dark brown, slightly covered with white scale-hairs. From Castro, Paraná (Brazil).

N. miasmoides Hopp (160 k) is extraordinarily similar to *miasma* externally, but the male sexual arma- *miasmoides*. ture is quite differently shaped; the very appendage itself of the 10th ventral segment (uncus) is quite different in the two species: broad and ending in three small broad tips in *miasma*, a single lobe only basally somewhat broader in *miasmoides*. The latter species is likewise known from South-East Brazil, e. g. from Uberaba in Minas Geraës.

N. nigrovenosa Drc. (= *Trosia venata* Schs., *Pod. pallida* Dogn., *Tros. schultzei* Hopp) (160 l) varies *nigro-venosa*. much in its colouring, which has led to the synonyms mentioned. Head from dark brown to yellow, thorax from white to brown, abdomen from yellowish white to yellowish brown, legs brown, tibiae and tarsi blackish. Also the forewing with a brown costa and brown-edged veins and the grey hindwing exhibit different tints. The species is widely distributed, especially in Costa Rica, Colombia, on the Amazon River, and in Peru; it occurs also rarely on the Itatiaya (ZIKAN).

N. beggoides Dyar (*Trosia*) (160 l) has white smooth forewings without transverse stripes, but with a *beggoides*. black costa, and externally it resembles *Mesoscia itatiayae* as well as *Macara pasaleuca*. Vertex of head yellow. Collar and the long patagia-hairs feebly yellowish, the rest of the thorax white. Abdomen suffused with yellowish. A common species in South-East Brazil.

N. fuscoapicata Dogn. (*Repnoa*) is a small white species scantily marked grey; the distal margin of *fusco- apicata*. the forewing, especially in the apical region, and the anal part of the abdomen are grey, the hindwing narrowly edged with grey, but the fringe white. From the Amazons. — **heringi** Hopp has exactly the same male sexual *heringi*. armature, so that it is probably only a race or form. It has purely white hair on the head and abdomen; without any yellow colouring. Forewing purely white, smooth, without stripes. Middle and hind legs white. From Paraguay and Argentina.

B. White species:

The great number of species with purely white wings exhibit but slight, mostly unreliable differences in their exterior. In most of the cases, the discrimination of these species is only possible in the males by reason of the very characteristic shape of the sexual armature, the exact description of which exceeds the scope of this work. Whosoever is more closely occupied with these species, may be referred to the special literature, particularly the "Mitteilungen aus dem Zoologischen Museum Berlin", 13th volume (1927), p. 209—336, and 15th volume (1929), p. 41—51, where most of the sexual armatures have been figured.

In normal cases, the white *Norape*-species look as follows: vertex of head yellow. Antennal shaft white or ochreous, more rarely reddish. Thorax white, with radiately arranged long hairs of the patagia (in fresh specimens). Abdomen suffused with yellow on the dorsum, or with a yellow tuft at the base. Forelegs black inside, the other legs white. Forewing with silvery transverse stripes, beneath with a blackish costal stripe which, however, may also be absent.

The following table of deviations from this normal case will facilitate finding a number of species:

a) All the tibiae and tarsi black: *muelleri* forma *atripes*, *virgo* (occurring also with white legs), *taurina*, *plumosa plumosa*, *plumosa biacuta* (occurring also with white legs), *jordani*, *nevermanni*, *insinuata*, *cornuta*, *obtusa*, *pampana*, *glabra*. However, there occur also species in which the black legs are covered with white scale-hairs.

b) Yellow colouring different: *argyrorrhoea* (abdomen white, *argyrorrhoea* f. *pruinosa* (also the vertex white), *cingulata* (without yellow), *zikaniana* (vertex white, but the tufts around the antennae yellow), *foliata* (without yellow), *fuscoapicata* and *heringi* (without yellow), *hadaca* (abdomen white), *damana* (vertex yellow, but the tufts around the antennal base almost white, colouring of abdomen unknown), *glabra* (variable, abdomen white or yellowish, vertex yellow, or yellow with a white tuft around the antennae, or all white), *albilineata* (vertex white, but the tufts at the antennal base yellow), *pampana* (abdomen white). The yellow colouring of *tamsi* is unknown. The yellow colouring of the abdomen is not to be confounded with the bands of the abdominal rings with parallel, frequently yellow bristles.

c) Forewings without transverse stripes: *albilineata*, *glabra*, *pampana*, *miasma*, *foliata*, *miasmoides*, *tamsi*, *heringi*, *argyrorrhoea*. The limit is not distinct, some species exhibiting hardly noticeable transverse stripes.

Finally, many species can be determined by their habitat, since most of the species are confined to a certain range.

We begin with three species forming together with the already mentioned *nigrovenosa* and *beggoides* a natural group by their 10th ventral segment (uncus) being trilobate, presumably produced by the uncus having grown together with the socii, by reason of which they were originally placed to the *Mesoscia*:

albilineata. **N. albilineata** Hopp (161 a). Forewing thinly scaled on the surface, but intensely scaled on the veins. Brazil: Esp. Santo, Itatiaya, Sa. Catharina.

glabra. **N. glabra** Hopp is a small species with smooth, not striped forewings. The neurulation varies somewhat. Sacculi long, bent, basally widened, gradually tapering at the end. A typical representative of the Argentine Pampas.

pampana. **N. pampana** Hopp is closely allied to *glabra*, likewise confined to the Argentine Pampas; externally recognizable by the absence of the yellow basal tuft of the abdominal dorsum. Uncus large, straightly truncated at the end, lateral tips pointed. The sacculi are longish, pointedly ending horns exhibiting a little swelling basally inside.

argyrorrhoea. **N. argyrorrhoea** Hbn. (= *Carama pura* Btlr., *Sulychra argentea* Btlr.) (161 a) is the most common species distributed from Texas to Buenos Ayres. Vertex yellow, abdomen without yellow hair. Forewing smooth, without transverse stripes. The males differ much in size, length of forewings: 11—17 mm. The costa of the forewing beneath exhibits a black streak not extending to the apex, but this streak is sometimes absent. The males are often also discernible by the sacculi projecting somewhat from the abdomen and being bent like a knee towards the uncus; the harpes are likewise bent like a knee, but towards the sacculi. — **N. pruinosa** Berg (= *Carama butleri* Baker, *Trosia euthula* Dyar) represents only a form of this species characterized by its purely white vertex. This form is by no means geographically confined, but to be noticed wherever the typical form lives.

vesta. **N. vesta** Schaus (161 a). The forewing of this small species shows 4 or 5 distinct transverse stripes at equal distances, extending from the inner margin to the posterior edge of the cell. The uncus is a small roundish club, spherical at the end. Brazil: Amazons, Esp. Santo, Rio de Janeiro, Itatiaya, Paraná.

cingulata. **N. cingulata** Jones (161 a). Forewing intensely striped, therefore with a bright silvery gloss, vertex yellow, abdomen with bright orange ringlets, but purely white hair. The uncus likewise ends spherically, but it is longer than in *vesta*. Harpes short and broad, straight at the end. Brazil: Alto da Serra (São Paulo) and Itatiaya.

hadaca. **N. hadaca** Dyar has likewise a yellow vertex, striped forewings, and a purely white abdomen, which combination is not to be noticed in the other white species of *Norape*. The uncus is long here, pointed lancet-like, thin and flat, the sacculi are stout, long, curved in the basal part, spherically thickened basally. A rare species. Mexico.

zikaniana. **N. zikaniana** Hopp (161 a). A species with remarkably red antennae, reminding us of the genus *Aithorape* which, however, is without any yellow colour. The vertex is white here, but the tufts around the antennae are bright yellow. Abdomen dorsally suffused with yellow. The uncus has the shape of an oval leaf. Brazil: Rio de Janeiro, Itatiaya, Sa. Catharina; presumably still farther distributed in South-East Brazil.

foliata. **N. foliata** Hopp is a small species, the smooth, stripeless forewings being about 11 mm long. Without any yellow colour, therefore similar to *heringi* externally. Uncus of the approximate shape of a narrow ivy-leaf. Sacculi broad basally, with slender, hook-like ends. Only 1 specimen known from Cucutá in Colombia, near the frontier of Venezuela.

N. tamsi Hopp. A small species with narrow wings. Length of forewings: 11 mm. Wings without *tamsi* stripes. It cannot be noticed in the only specimen whether the head and abdomen exhibit any yellow colour. Uncus delicate, broad at the base, obtuse at the end. The sacculi are bulbous chitine-plates, scantily set with cilia. Buenos Ayres.

N. muelleri Hopp. Stripes of forewing rather indistinct, costa beneath white. Uncus broad, short. The *muelleri* sacculi are short, feebly arched chitine-walls the anterior edge of which bear one large, crooked or straight thorn each on the sides and in the middle. Mexico, Guatemala, British Honduras. A form of this species has black middle and hindlegs — f. **atripes** Hopp. *atripes*.

N. variabilis Hopp is not easy to determine, as it varies extraordinarily in many respects. Length of *variabilis* forewings 11—18 mm, width 6—10 mm. In general it is a species with rather small, narrow wings. The uncus is a delicate, obtuse triangle. As the sacculi can be rolled up, they vary in shape from one specimen to the other. They usually represent small, notched chitine-walls. Widely distributed: Pará, Brazil, on the whole Amazon River as far as Peru, in Colombia and Venezuela. A form was separated with a broad blackish collar — **atricollis** Hopp, from the Upper Amazon R. *atricollis*.

N. virgo Btlr. Like several other species, it has black tibiae and tarsi. The uncus is short, roundish, *virgo* broad, delicately chitinized, but edged by broad chitine-listels. Sacculi bent geniculately, with a thorn at the end, but of different projections. Texas, Mexico, and Colombia. A form is separated with white middle and hindlegs — f. **albipes** Hopp. Mexico. *albipes*.

N. cretata Grt. is not distinguished as an imago from *virgo* f. *albipes*. Only DYAR's statement that the *cretata* larvae of *virgo* and *cretata* are distinctly different, forces us to separate this species for the present. In case of the differences in the larvae being explained as an error, *cretata* would have to be regarded as the species (*albipes* being a synonym) and *virgo* as its form (with black legs). *cretata* is known from the southern states of U.S.A. — Larva, according to DYAR, in the surroundings of Washington, on *Cercis canadensis*; with long white hair, marked with yellow, brownish red, and black. Cocoon in the earth in September, emerging in July.

N. nevermanni Hopp is allied to *virgo*, likewise with black legs. The uncus is longer, almost just as *nevermanni* broad at the end as at the base. Costa Rica, Panama.

N. taurina Hopp has also black tarsi. It is smaller, on an average, than *virgo* and *nevermanni*. The uncus *taurina* is similarly built as in *virgo*, somewhat narrower at the base. Very differently shaped, however, are the sacculi looking like tiny, basally very broad cow-horns. Mexico, Guatemala.

N. caprina Hopp. Size very different, length of forewings: 10—15 mm. The uncus is an oval, rather *caprina* small, delicate lobe. The sacculi are strongly curved horns arising from the sides of an irregularly dentate plate. British Guayana, Venezuela, also from the Upper Rio Negro, Colombia.

N. arietina Hopp, near *caprina*, with a similarly built uncus. The sacculi are rather large, triangular- *arietina* roundish plates terminating into short thick horns. From the Amazons: Manaos, Santarem, also from the Rio Essequibo in British Guayana.

N. capreolata Hopp. The uncus is an obtuse triangle framed with thick chitine-listels, according to *capreolata* which the species may belong near *virgo*. The sacculi bear one lateral branch each at the end and in the middle, but they are of variable shapes. Colombia: Muzo.

N. truncata Hopp. The uncus is short, very broad, arched somewhat like a hood. Sacculi long, flatly *truncata* curved, broadly truncated at the end, proceeding from the abdomen. According to the shape of the anellus, the species is divided into three geographically separated races: *truncata truncata* Hopp; anellus roundish in front, convexly arched, not pointed, bearing a small roundish appendage in the middle. Merida and Caracas, Venezuela. — **cavata** Hopp; anellus more intensely chitinized, broad, concavely arched, gradually pointed *cavata* in front. North Peru (Rio Charape) and Colombia (Central Cord.). — **hastata** Hopp. Anellus narrow, intensely *hastata* chitinized, extended into a long point. South Colombia (Cali, Popayan, Pasto) and Panama.

N. schausi Hopp. Uncus very broad and short, with a short broad tongue in the middle. The sacculi *schausi* are distantly separated, falciform horns with long appendages towards the inner sides. Costa Rica: Guapiles and Sixola. A rare species.

N. draudti Hopp. Uncus tongue-shaped. The sacculi are slender, long-hooked clasps, basally widened *draudti* spherically. The length of the sacculi varies. A common species from Mexico.

N. obtusa Hopp. Uncus very broad and short, as in *schausi*, but centrally tapering into a short point. *obtusa*. Sacculi feebly bent, long, broadest basally, gradually narrower and then again broader and flatter, feebly den-

tate on the inside and slightly bent in the end-part, distinctly interrupted narrower to the roundish-truncate end. Rather widely distributed: Bolivia, on the Upper Amazon R., Uberaba (Minas Geraës).

damana. **N. damana** Hopp. Vertex yellow, almost white around the antennae. Forewing very indistinctly striped. It is not known, whether the abdomen shows any yellow colour. The only specimen at hand has an uncus similar to *puella* and *miasma*. The large harpes are basally broken up into bands. Sacculi short, roundish obtuse, scantily haired, passing broadly knee-shaped over into the tegumen, which is interrupted between them, and connected with the base of the harpes by a band. Alto Paraná (Argentina, Paraguay).

testudinalis. **N. testudinalis** Hopp. Uncus basally broadly divided into two rather narrow branches, with a short roundish lobe in the middle. Harpes extraordinarily long, projecting far beyond the uncus. The sacculi are large dark brown, smooth, glossy chitine-walls with slight details, round at the end, broadly angled on the insides and from there to the base broadly undulate. West Colombia: Rio Micay and Bella Vista near Tumaco, numerous.

Insinuata-Group.

The species of this group can be comprised by the similar structure of the uncus and are probably related to each other.

insinuata. **N. insinuata** Hopp has blackish tibiae and tarsi, and the costa of the forewing beneath is blackened almost to the apex. The uncus is an oblong lobe broadly rounded in front, dorsally with two bare narrow parallel ridges. The sacculi viewed ventrally look almost just like those of *plumosa-angustior*, but dorsally seen they are sharply flawed, the end-part more or less broadly lancet-shaped. From the Upper Rio Negro, Colombian Eastern Cordilleras, and from Peru, Carabaya.

cornuta. **N. cornuta** Hopp has also blackish tibiae and tarsi, and a blackened costa of the forewing beneath. The uncus widens gradually at the base, but it is otherwise similar to *insinuata*, and the species may be considered as a race. The sacculi differ from *insinuata* in the end-part, ventrally seen, being uniformly narrow and terminating into a small, interrupted, still narrower end-part. From East Ecuador, El Rosario, Rio Pastazza.

consolida. **N. consolida** Hopp has white middle and hindlegs, the costa of the forewing beneath is white. The uncus is flatter and shows a broad bare zone dorsally in the end-part at that place where a narrow raised double ridge is to be seen in *insinuata*. The sacculi, when seen dorsally, likewise exhibit a flaw which, however, is situated in the basal third, the remaining larger part of the sacculi is tapering only quite in front and thereby makes a very clumsy impression. Bolivia, Chulumani.

cathara. **N. cathara** Dyar. Middle and hindlegs grounded black, but covered with white scale-hairs. The species is smaller on an average than *plumosa-angustior*, with less distinct transverse stripes on the forewing, the antennae more red. According to the uncus, the species belongs to the *insinuata*-group, it is somewhat winged, widened at the base. Sacculi very similar to *plumosa-angustior*, without the sharp flaw of the *insinuata*-species, still more pointed at the end than *angustior*. Paraguay.

Plumosa-Group.

This group can also be comprised owing to the similar structure of the uncus which is rather flat, long, narrow, truncate at the end, thus of the approximate shape of a short needle-leaf of a fir-tree.

plumosa. **N. plumosa** Btlr. Sacculi long, slender, bent, proceeding from the abdomen, suddenly tapering at the end into a bent point. Legs blackish. Brazil: Para and Lower Amazon R., Guiana, Venezuela. The size of the species is rather variable, length of forewings: 15—19 mm. — **biacuta** Hopp. The ends of the sacculi have two short points. Middle and hindlegs blackened or white. Bolivia, Peru, Upper Amazon R. and Colombia (*angustior*, Muzo). — **angustior** Hopp. The sacculi terminate narrow into a gradually narrowing, less bent end-part. Legs white. Brazil: Rio de Janeiro, Itatiaya, Minas Geraës, Sa. Catharina. A common species.

jordani. **N. jordani** Hopp is allied to the *plumosa*-forms in the structure of the uncus. Middle and hindlegs blackish. Sacculi thicker, but shorter, and the end-part is distinguished by a small, less chitinized tongue set with touch-cilia, and by a small exterior intensely chitinized appendage. Only 1 specimen known, from French Guiana.

*Walker*i-Group.

This group approximates *plumosa* in the uncus which is very similarly built, narrow, long, somewhat thicker. Besides, the species united here form an interesting series of development in the shape of the

sacculi on which three parts can be distinguished, i. e. the foot, the ventrum, and a thorn at the end.

N. walkeri *Btlr.* This species initiates the series of developments; the sacculi are here of the most complicated structure. The most remarkable feature is that they can be freely moved and turned round an axle like the balance of a watch. The foot, partly concealed behind the large anellus-shield, is very large and studded with numerous little spikes. The ventrum is very hairy on the interior sides. The anal part is shaped almost like the head of a bird with a very short, strongly chitinized beak corresponding to the thorn in the other species. The size of the males differs considerably: length of forewings between 17 and 22 mm. Range: from Pará to Obidos on the Amazon R., Guiana, Minas Geraës (Uberaba), Itatiaya.

N. tosca *Hopp.* This species exhibits the next stage of development of the sacculi: the foot is reduced to a stout stump and without spikes. The ventrum is still very hairy though not so densely as in *walkeri*, the dark chitinized anal part of the sacculi is produced into a plump thick thorn, longer than in *walkeri*, shorter than in the following species. A small species: length of forewings about 15 mm. Argentina: Tucuman.

N. xantholopha minor *Hopp.* This species shows a further modification of the sacculi. The foot is narrower. The ventrum exhibits but few single hairs, but it has remained less chitinized. The thorn has become slender and already similar to the following species. The species is still smaller than *tosca*. Length of forewings: 11—13 mm. Hitherto only known from Eastern Peru, Rio Pachitea. — **xantholopha xantholopha** *Dyar* (= *corporalis* *Hopp.*). Here the sacculi are still more modified: the foot is still smaller and more slender, the highly arched ventrum is strongly chitinized and without any hair, the thorn is placed quite outside and does not project beyond the foremost part of the ventrum. This form is widely distributed in Mexico, Guatemala, Panama (but so far not known from Costa Rica), Colombia, Ecuador. — **major** *Hopp* differs from the preceding form in the thorn of the sacculi projecting far beyond the ventrum. Central Colombia. Larger on an average.

N. acuta *Hopp.* Here the ventrum of the sacculi is extended at the end into a sharp point. The species is of variable sizes: length of forewings 13—18 mm. Guatemala, Costa Rica, and Panama.

N. rothschildi *Hopp* likewise belongs to the *walkeri*-group, but it has taken a special development. The uncus is extremely long, almost semicircularly bent, massive, roundish, projecting far beyond the abdomen, with a small, spiked shield at the apex. The sacculi are also very large, spoon-shaped if viewed from the side. without a defined foot, with a hairy ventrum the basal part of which is finely dentate, and with a thorn shaped similarly to that of *walkeri*. One of the largest species of *Norape*: length of forewings 19—21 mm. Peru and Upper Amazons.

C. Species of an undetermined position.

N. ovina *Sepp.* This species which had played an important part among the *Megalopygidae* in early literature, cannot be determined at present. SEPP figures the ♀ with an expanse of about 45 mm, with striped forewings, a blackened costa of the forewing beneath, and yellow ringlets of the abdomen. The larva is yellow with black stripes and lives on *Panicum plicatum* in the surroundings of Paramaribo, Dutch Guiana. The pupation takes place underneath the surface of the earth or wrapped up between leaves. ♂♂ bred at the habitat might reestablish the species.

N. discrepans *Wall.* (*Mallotodesma*), likewise described according to a ♀, shows white antennae, a yellow vertex, a white abdomen with yellow ringlets, and a yellow hair-tuft on the dorsum, with white middle and hind legs, the forewing beneath with a slightly brownish costa. The habitat is stated to be Brazil. This description would apply to more than a dozen species.

N. cretacea *Hopp* (*Repnoa*). Likewise a ♀, a small species with an expanse of 23 mm. Completely white, forewing without stripes. Bolivia. This species probably does not belong to the *Norape*.

Finally, according to the present elaboration, the females of all the white species of *Norape* cannot be determined. In some cases, the slight external differences of the species suffice for the determination of the females, if they are yet within the original takings. Thus, for instance, the ♀♀ of *zikaniana*, *albilineata*, *argyrorrhoea*, *cingulata*, *vesta*, *heringi*, *cathara* are rather well discernible by the external marks of the ♂♂ (*cathara* by their red antennae). The determination of the ♀♀, however, by reason of sure morphological differences, i. e. the shape of the genital organs, is reserved to the future. These organs will probably also exhibit considerable differences in shape.

Additions.

On p. 1083, insert after *M. dyari*:

interpunctosa. **M. interpunctosa** Dogn. (described as *Mesoscia*) is allied to *dyari* and may likewise be regarded merely as a race or differently coloured form of *alydda* Drc. The ♂ has a blackish ochreous head, thorax and abdomen the greenish yellow forewing with a series of black internerval spots; hindwing light ochreous. Colombia, Tolima.

alydda. **M. alydda** Drc. (described as *Alpis*) (161 c). The silky brown forewing with a blackish costa and black basal spot are separated from the light distal margin by black, outside whitish, spots. Hindwing light yellowish. Head, thorax, abdomen and legs brown. Costa Rica, Ecuador, Peru. — DOGNIN describes another *nigella.* Colombian form with a different colouring, of which only the ♀ is known: — **nigella** (described as *Norape*) with blackish or dark grey hindwings and isochromatic or olive brown colour. Colombia: Tolima. It may be that *nigella* represents merely the ♀ of *interpunctosa*.

On p. 1085, insert after *N. jaromillo* Dogn.:

isabela. **N. isabela** sp. n. (161 c). Head yellow, thorax, abdomen and legs yellowish white, the forelegs brownish on one side. Forewings ochreous, all the veins ruled with broad white lines. Hindwing yellowish white. Peru: Oconeque, Carabaya (G. OCKENDEN). Type in the Tring Museum.

II. Megalopyginae.

The *Megalopyginae*, as we have already mentioned, are not to be separated into genera and species in the same sense as the *Trosiinae*, because the appendages of the 10th and 9th segments of the male abdomen, which form stages of development in the *Trosiinae*, have stopped on the very same point of organizatory development in the *Megalopyginae*. Whatever remains of sexual-morphological differences of the ♂♂, must be used with the same caution for the distinction of the species as other differences, the neurulation, marking and colouring, hair and scales. On the whole, these differences are scanty, and not always indubitable as regards constancy. Accordingly also the species are partly very closely allied to one another, and the whole of the *Megalopyginae* exhibit quite closely contiguous elements of marking and colouring. Another difficulty for the determination of the species is the extraordinary variability of widths according to the size of the individual insects, the width of the wings, the length of the antennae, of the colourings and the markings produced by them. This variability of widths is presumably caused by the single individuals having different lengths of life as larvae. Especially the full-grown larva can, according to observations, immediately proceed to its pupation or remain for many months (up to 18 months) unpupated in the spun cocoon, whilst the pupal stage seems to be confined to a time of about 4 weeks. In this way all the stages of development are to be found throughout the year, particularly in the districts without definite rainy seasons. Whether the larvae feed during the dry or rainy seasons, is of great influence upon the size of the individual insects and upon the development of pigments. In this connection is also the formation of decidedly melanistic specimens. Moreover, the ♂♂ and ♀♀ of the *Megalopyginae* sometimes differ considerably in colouring and marking. Finally, the ♂♂ are sometimes observed to approach individually the ♀♀ in colouring and marking, the ♀♀, however, to approximate the male marking and colouring; thus are produced gynomorphous ♂♂ and andromorphous ♀♀, and in extreme cases occur individual insects which, from the antennae (♀ from more feebly pectinate to plain) to the anal hair (♀ distinctly curled hairballs) are completely ♂♂ on one side and ♀♀ on the other side (*Meg. lanata*).

We divide the *Megalopyginae* into two genera, *Megalopyge* Hbn. and *Podalia* Wkr. They differ in the ♂ of *Megalopyge* lacking the retinaculum of the frenulum, whereas in *Podalia* it is developed. The numerous other genera that have been established cannot be maintained owing to the inconstancy of the marks of distinction used. Thus belong to *Megalopyge*: *Gasina*, *Alpis*, *Zebonda* Wkr., *Chrysopyga*, *Ochrosoma* H.-Sch., *Oylothrix*, *Pimela* Clem., *Lagoa* Harr., *Cyclara* Schs. To *Podalia* Wkr.: *Gois*, *Malmis*, *Bedalia*, *Unduzia* Dyar.

1. Genus: **Megalopyge** Hbn.

Nuda-group.

nuda. **M. nuda** Stoll (= *partheniata* Dyar) (161 c). Wings scantily scaled, the veins on the forewings with fine black lines on both sides, but only those proceeding from the cell-end extend to the distal margin. Fine black streaks between the veins. Hindwing with fine black hair on the veins. The ♀ has the same, but sometimes much darker ground-colour on the wings. The other colourings are very variable: head, thorax, abdomen

and femora yellow or rufous brown, dark brown to blackish, the thorax mostly mixed with white and black, which mixture passes over to the basal area. Tibiae and tarsi black and white, with long hair. The insects easily lose part of the vestiture of their wings, especially the black lines, and the ♀♀ look then uniformly light or dark brown, their anal ball being from light yellow to black. The larva is represented by mistake in STOLL according to the precise description by DEWITZ; it lives in Venezuela, on a yellow-blossoming Cassia, and other plants. The larvae live unupated in the cocoons for as long as 18 months and in this way sometimes reach Europe alive. Widely distributed: Guiana, Venezuela, Paraguay, South Brazil, Bolivia, Peru.

M. krugii Dewitz (161 c) is similar to *nuda*, but much smaller. The black lines between the veins are *krugii*, broader but less distinct, the veins themselves with whitish hair. A black spot at the cell-end of the forewing is preceded by a brightening. Unlike *nuda*, the ♀♀ are here sometimes much lighter coloured than the ♂♂. Larva and cocoon according to DEWITZ similar to *nuda*; on Rosa. — Portorico, Cuba, Colombia.

M. salebrosa Clem. (= *agdamea* Drc.) (161 c). A large, distinctly marked species reminding us of *nuda salebrosa*, by the fine lines of the middle part of the veins, although its colouring and marking forms a transition from *nuda* to the *xanthopasa*-group. Mexico, Guatemala.

Lanata-group.

M. lanata Stoll (= *citri* Sepp) (161 d) is one of the commonest, most widely distributed species, varying *lanata*, in size, colouring and marking partly individually, partly geographically. The head, 6 thoracic spots and the long femoral hair on one side are pinkish red, the abdomen dorsally with pink rings, the wings frequently with a slight pink hue, especially in the ♂. A white zone in the median area of the forewing, interrupting the marking, is sometimes very extensive (Venezuela). Mexican specimens are darker and more hazily marked, those from South Brazil mostly distinctly marked and sometimes very similar to *urens* Berg. There are also cases in which the ♂♂ assume the faded marking of the ♀♀, or the ♀♀ the distinct marking of the ♂♂. A half-sided intersex or hybrid has become known from Sa. Catharina. Larva (figured by SEPP, biology by JONES) whitish, with dark red tubercles from which the long dark brown and the short blackish venom-hairs arise. It lives on numerous trees and shrubs, also on foreign ones, such as *Mangifera indica*, *Citrus aurantium*.

M. urens Berg (161 d) is allied to *lanata* and exhibits all its details of markings. Only the colouring *urens*, is somewhat different, the dark brown tints are more blackish here, the light brown ones more whitish, the pinkish-red ones often reduced and smaller than in *lanata*. The ♀ of *urens* has the same marking and colouring as the ♂. The larvae of the two species differ distinctly, especially in the hairs of *urens* being mostly spatulate and the tubercles yellowish or greenish instead of purple. The larva, according to BERG, lives on *Feijoa sellowiana* Berg, but according to BOURQUIN (in litt.) it occurs also on Citrus, Rosa and many other trees and shrubs of Argentina, South Brazil, Uruguay, Argentina, Paraguay. BERG states also Venezuela, but this probably refers to *perseae*.

M. perseae Dogn. (161 e) is distinguished by the light, yellowish-pink ground-colour of the wings and *perseae*, by plain, somewhat wedge-shaped dark stripes between the veins. The ♀ has the same colouring and marking as the ♂. The cocoons of this species were found at the foot of the tree *Laurus perseae* L. Peru, Ecuador, Colombia, Venezuela. — The author distinguishes from this another species — **translucens** Dogn. with hyaline *translucens*, wings and the same, but less distinct markings, short black fringes, while the fringes in *perseae* are ochreous, interrupted by black. Vertex black (*perseae* ochreous). From the Tolima and Quindiu, Colombia.

M. torva Schs. (161 e) is a rare species, of which only the ♂♂ are at hand so far. The type is from Costa *torva*, Rica, other specimens from Peru, one of which is figured. The species looks like a small *Podalia fuscescens* with indistinct postmedian markings of the forewing, or like a large *M. albicollis* with a slightly modified colouring and marking. It is characterized by the brownish colour of all the white markings and the whitish, distinctly defined, black-centred spot at the base of the forewing, as well as a double tuft of blackish-brown hairs at the base of the abdomen. The hair of the basal area of the forewing is undulate, and we may assume that the ♀♀ exhibit distinctly curled white hair also at the costa of the forewing.

M. tharops Stoll (= *multicollis* Schs.) (161 e). The problematical figure by STOLL seems to represent *tharops*, a badly preserved and wrongly figured ♀; the author himself remarks that the white stripes of the wings are somewhat transparent. Judging from *multicollis* Schs., the species is widely distributed: Guiana, Venezuela, Panama, Colombia, Amazons, Ecuador, Peru, Minas Geraës. The size of the specimens and the colouring varies considerably here, too; there occur such with entirely white hindwings, while the inner margin is generally brown.

lampira. **M. lampira** Dyar (161 e) represents the Mexican edition of this species, distinguished by the larger extent of the dark area of the forewing at the inner margin. Described and figured as *radiata* in Biologia Centr. Amer.

radiata. **M. radiata** Schs. (161 f) is likewise closely allied and forms the southern race of *tharops*. The brown or light brown tints of *tharops* are blackish-brown here, all the white is more reduced. Whilst the prothorax and tegulae of *tharops* ♂ ♀ exhibit one white saddle each, the prothorax of *radiata*-♂ and also the tegulae of *radiata*-♀ are blackish-brown. South-Eastern Brazil: Curityba, São Paulo, Itatiaya, Passa Quatro. Larva according to Jones (where it is determined as *tharops*) on Guava, partridge-coloured, ripe for spinning at the end of March, but it emerged only in January after 320 days. — **flavivertex** Schs. with a yellow (instead of white) vertex is a somewhat differently coloured form occurring similarly also in other species. São Paulo.

albicollis. **M. albicollis** Wkr. (= *grandis*, *fasciata* Wkr., *vipera* Schs.) (161 f). The ♂ has a white vertex, the ♀ a brown one, besides the white and brown hair of the basal area of the ♂ forewing is smooth, or indistinctly curled only at the base of the wing, while it is distinctly curled in the ♀ beyond half of the wing; the curled hairs easily fall off. This species likewise exhibits considerable differences of size and colourings from blackish-brown to light brown. Especially the intensity of the white colouring varies frequently; for instance, specimens with a reduced white colouring of the forewings exhibit the generally white tufts on the femora and tibiae brown. Moreover, we meet with a yellow (instead of white) colouring of the vertex and tegulae. Widely distributed from Panama to Bolivia and South Brazil, Guiana, Amazons. — **superba** Hy. Edw. is the Central American race of *albicollis* distinguished by the claws, especially on the hind feet, being white-haired at the base. Generally also the brown colouring is somewhat lighter. Mexico. The same race occurs also in Guatemala, Honduras and Costa Rica, but also the typical *albicollis* and transitions between them occur here; the transitory forms are especially characterized by the claws, particularly those of the hind legs, exhibiting only single white hairs at the base.

braulio. **M. braulio** Schs. (161 g) may be considered as the Paraguayan local race of *albicollis*, but the differences (wings coloured more yellowish-grey, with a less distinct white marking of the postmedian area of the forewing) disappear in the series compared with South Brazilian specimens. In general, the South Brazilian male specimens exhibit lighter hindwings, while those of the female hindwings are always dark brown.

peruana. **M. peruana** sp. n. ♂ (162 a). Judging from the marking, this species is about intermediary between *torva* and *tharops*, uniting the elementary markings of the two species. Head, collar, and legs pinkish-brown, the thorax mixed with white. Abdomen pinkish-brown. Wings likewise with a pinkish-brown hue on them, the forewing at the distal margin with veins lined black on both sides, the median area pinkish-brown, the basal area blackish. Hindwing brown, lighter between the veins. Peru: Carabaya, San Domingo (OCKENDEN). Type in the Tring Museum.

Apicale-group.

apicalis. **M. apicalis** H.-Sch. (*Ochrosoma apicale* = *Zebonda basigutta* Wkr.) (161 g). The colouring and size also of this species vary considerably. The ♂ shows a white spot near the base of the forewing, which is absent in the ♀. The ♀♀ generally show a uniformly thin cover of blackish scales, with a yellow apical spot of the costa of the forewing and yellow fringes at the anal margins of the hindwings. The ♂♂ which sometimes exhibit the same colouring may have also yellow veins, especially on the forewing, and the hindwings are usually lighter. Forelegs from light yellow to white. Abdomen with a blackish dorsal stripe, or quite dark brown. Described from South Brazil, but widely distributed, Guiana, on the Amazons as far as Peru, Colombia.

lecca. **M. lecca** Drc. (161 g). Larger than *apicalis*, from which it differs also in some details of the marking. The yellow apical spot of the forewing is absent, and the veins are not prominently yellow. At the cell-end, however, there is a light spot. The distal-marginal area of the forewing is lighter, distinctly visible in the ♀♀. As in *apicalis*, the ♀ lacks the white spot near the base of the forewing. Besides, the legs of the ♂ are white, those of the ♀ brown. This species likewise exhibits considerable variations of size and colourings from light brown to blackish brown.

hina. **M. hina** Dogn. (162 a). ♂ similar to *apicalis* with the light veins and the yellow prolonged apical spot of the forewing, but it lacks the white basal spot and exhibits a small dark spot at the cell-end. Considerable differences of size and variable intensities of colouring occur also here. Sometimes a yellow costal band is to be seen on the last third of the forewing as far as the apex. The ♀♀ exhibit a darker colouring on an average. Guiana, Amazons to Peru, Panama, Colombia.

Trossula-group.

trossula. **M. trossula** Dogn. (*Prismoptera*) (162 a) has hyaline wings, except scanty brown and black hair at the base of the forewing and at the inner margin of the hindwing. Fringe black. Head and thorax brownish ochreous,

abdomen somewhat darker. Legs black, partly intermixed with white hairs. Cocoon reddish yellow. Chiriquibamba near Loja, South Ecuador. ♀ unknown.

M. hyalina Schs. ♂ (162 a) has likewise almost hyaline wings. Forewing with a black costa and a scantily black-haired basal area. Hindwing with longer black hair on the inner-marginal area. Vertex and collar ochreous, abdomen black with an ochreous anal tuft. Legs dark brown. ♀ blackish, thinly scaled with whitish markings: a large spot occupying the end of the cell, a broad band from the costa near the apex to the angle of the inner margin. Head, thorax, abdomen dark brown, anal ball dingy yellowish. The ♀ thus reminds us of forms of the *undulata*-group. Larva, according to ΖΙΚΑΝ, fox-coloured, cocoon black. South-Eastern Brazil.

Xanthopasa-group.

A group containing few species but many forms, partly composed of local races, partly of individual variations. Variable is particularly the size of the individual insects, the gradual development of brown pigments and white markings, and also the width of the forewings producing specimens with broad and narrow wings. Similar conditions have already been observed in the *Trosiinae*-species which are strictly confined in sexually morphological respect. Beside the species and forms described, most of which are figured, there are quite a number of such that are not denominated. We divide the group into two series, the first of which, the *opercularis*-series, shows the white basal spot of the forewing indistinct, strigiform or undeveloped, while it is roundish and more distinctly developed in the second, the *defoliata*-series. The white hairs of these *Megalopyge*-species, however, fall off easily.

Opercularis-series.

M. opercularis Abb. & Sm. (= *Pimela lanuginosa* Clem.) (162 b) lives in the Southern United States, but it is hardly separable from the Mexican — **ornata** Drc., as both are variable in size and colouring, forming transitions. On an average, the white submarginal row of spots on the forewing may be more rarely developed in *opercularis* than in *ornata*. The latter occurs also in Guatemala, Costa Rica and Panama, where it passes over to — **briseis** Dyar (162 b) which is typically described as a somewhat larger, darker pigmented species from Venezuela; it likewise often shows the submarginal row of white spots on the forewing. Slighter differences of tints are met with in the Guianas, in Colombia, Ecuador, Peru and Bolivia. Some of them have been denominated: — **govana** Schs. (162 b) from French Guiana, — **incachara** Schs. (162 b) from Bolivia, and — **albizona** Dogn. from the Amazons. The latter which is very closely allied to *govana* shows a more extensive white marking on the wings. Especially the thorax exhibits a broad white belt at the base, and the abdomen a white anal tuft; the forewing is white in the cell, below the media and at the base of the veins, and a white postmedian line crosses the wing. Moreover, there are still whiter coloured specimens at hand from Peru, exhibiting an entirely white thorax and an almost white abdomen. — An *ornata*- or *briseis*-form with narrower, slightly prolonged forewings is — **costaricensis** Schs. (162 b) occurring not only in Costa Rica but also elsewhere, e. g. in Panama and South Colombia. — Another variety of *opercularis* or *ornata* has been named — **bissesa** Dyar (162 c), typically in Arizona and Mexico; it differs in the more distinctly defined, broader, light yellow distal margin of the forewing, but there are transitions to the nomenclatural form. Also *briseis* varies similarly, exhibiting forms with a light yellow margin from Venezuela, Guiana and Para.

M. amita Schs. (162 c) is the southern representative of the *opercularis*-series and probably to be regarded as a distinct species, but it is likewise subject to considerable variations. The white marking of the forewing is sometimes very distinct, the lemon colour of the body passes over into brown: — **victoriana** Schs., and individual specimens occur, which represent distinct transitions to certain forms of *M. undulata*. South Brazil, Argentina.

M. amitina Dogn. is not at hand. The ♂ is covered with blackish-grey curled hair on $\frac{2}{3}$ of the forewing, the distal-marginal area and the fringe being yellow. Hindwing pale yellow. Head, thorax and abdomen yellow, legs black. Trujillo, Peru.

M. chrysocoma H.-Sch. (= *aricia* Schs.) (162 c). The ♂ has dark brown wings with scanty hair; the costa of the forewing, especially before the cell-end, is blackish, an indistinct whitish spot is at the cell-end. Body ochreous, a stripe of dark brown hairs directly before the yellow anal tuft. The ♀ has a yellowish ground-colour of the wings, suffused with dark greyish brown. Venezuela.

M. megalopygae Schs. Vertex lemon-coloured, thorax olive brown, abdomen above dark brown, subdorsally with a basal lemon-coloured tuft. Forewing dark grey, with long curled hair turning olive yellow along the proximal and distal margins. Hindwing dark grey, the distal margin and fringe narrowly olive yellow. French Guiana.

undulata. **M. undulata** H.-Sch. (= *fuliginosa* Moore, *vulpina* Schs.) (162 c) varies extraordinarily in size, colouring from olive brown to blackish brown and in the intensity of the white markings in both sexes; it was observed that uniformly dark brown ♂♂ may belong to ♀♀ which are much lighter and provided with abundant white markings, whereas on the other hand the brightly coloured ♂♂ sometimes emerge with plainly dark brown ♀♀ from the same breed. South-Eastern Brazil. The much smaller, more distinctly marked specimens from *vulpina.* Argentina are — **vulpina** Berg (162 d), forming regular transitions to *amita* Schs. — **sevarina** Schs., described *sevarina.* from Paraguay, is closely allied to *undulata*. The ♂ has paler hindwings and the ♀ is broader and darker coloured. — The larva of *undulata*, according to JONES, with black, white and brownish ochreous spatulate hair, lives on Guava (São Paulo) and other plants. Cocoon in a dense web into which the larval hair are intermixed.

uruguayensis. **M. uruguayensis** Berg (162 d). Head, thorax and abdomen brownish ochreous, intermixed with white. Wings thinly scaled, with indistinct white markings, especially in the cell. Uruguay, Argentina. — A form with more distinct white markings, especially white veins and more extensive white colouring of the cell of *chacana.* the forewing, which shows a large dark spot at the end, has been denominated — **chacana** Schs. (162 d). From the Chaco in Argentina.

lanceolata. **M. lanceolata** Dogn. ♂ with a brownish ochreous head and body, blackish legs. Forewing brownish ochreous, paler in the lower median area, the costa and the anterior part of the basal area blackish: the cell is white and forms the point of a lance, the point being turned inward. Two white distal-marginal lines approach each other at the apex. Hindwing white, feebly brownish. La Rioja, Argentina.

inca. **M. inca** sp. n. (162 d). Head ochreous, white between the antennae. Thorax, abdomen and legs ochreous, tibiae and tarsi black, white-haired on one side. Forewing brown, costal area dark brown; marked with white arc: the costa, the anterior and posterior edges of the cell as well as the media of the cell with fine white hair, the cell-end blackish, a broad white spot at the costal apex. Hindwing brown, lighter at the base. ♀ unknown. Peru: between Lima and the Chanchamayo (A. M. Moss). Type in the Tring Museum.

Defoliata-series.

defoliata. **M. defoliata** Wkr. (162 e). We figure a specimen corresponding to the type. Mexico. The species has been wrongly determined by DYAR and corresponds approximately to his *trujillo.* *trujillo* Schs. (162 e) which is to be regarded as the darkest coloured form of this series. Much lighter coloured *agesistrata.* than *defoliata*, however, is — **agesistrata** Drc. (162 e) which might correspond again to DYAR's *codiopteris*. Darker specimens than the figured Guatemala-specimen occur of *agesistrata*, and in nature there may be transitions from the lightest *agesistrata* to the darkest *trujillo*. The type of DRUCE is a badly preserved ♀ from Guatemala, according to which the author determined later on a ♂ evidently belonging to this form. Whatever DRUCE denoted as *agesistrata* later on, seems however to belong partly to *ornata* Drc. Mexico, Guatemala.

A Mexican form with a still more extensive brightening is allied to *agesistrata*. It is the form which DYAR determined as *defoliata* by mistake and which has thus remained without a denomination; it may be *dyari.* called: — **dyari** nom. nov. (162 a). The distal-marginal area of the forewing is distinctly defined light yellow, the basal area brown, blackish towards the costa.

The form *dyari* is of special importance, because it represents the Mexican edition of the oldest species *xanthopasa.* described of this group — **xanthopasa** Sepp from Dutch Guiana, of which no specimens are at hand. The Guiana-species chiefly differs from its Mexican form in the darker brown thorax and abdomen which are light yellow spotted with brown in *dyari*. SEPP figured only the ♂♂; the ♀♀ might be identified with *pellita* Felder (from French Guiana), the figure of which could not be reconstructed. — Finally we may mention the occurrence of a form of the *defoliata*-series also in South Brazil, from São Paulo, "Sierra de Cubatao". Head, thorax and abdomen light brown, forewing almost similar to that of *agesistrata*, though with a smaller white basal spot, hindwing intensely brown near the inner margin.

Two melanistic aberrations of *Megalopyge*-species of the *xanthopasa*-group are at hand from the Tring Museum, one of which we figure. Here the wings are completely black, as well as the legs and the abdomen, but the latter with a light yellow anal tuft. Head and thorax brownish ochreous, the thorax with a light yellow saddle at the base. This aberration the relation of which to one of the many chromatic forms *melaina.* can no more be ascertained owing to the black cover of the wings may be named — ab. **melaina** n. f. (162 f); Para (M. Moss). The other aberration was also collected by M. Moss on the Upper Amazon R. and has much narrower wings which are dark brown like the thorax and abdomen. The thorax has a lighter tuft at the base,

the abdomen a light yellow anal tuft. Head light yellow. The legs are normally coloured, with long white hairs on one side, black tarsi, and white-haired claws.

The following further species are allied to the *xanthopasa*-group.

M. pyxidifera *Abb. & Sm.* (= *subcitrina* *Wkr.*) (162 f). Completely brownish ochreous. The ♂ has curled hair in the basal part of the forewing, the ♀ also along the costa. Hindwing somewhat lighter. Southern Atlantic States. *pyxidifera.*

M. crispata *Pack.* (162 f) is pale yellow in all its parts, except the blackish embedding of the head in the thorax and the marking of the forewing. Also the ♂ has black, brown and white curled hair along the costa. A black spot without the cell-end. Northern United States. — An aberration — a ♀ — has been described — ab. **grisea** *Barnes & McD.*, in which the forewing and hindwings above and beneath exhibit a grey ground-colour and white fringes, but otherwise the marking of the typical species. Newark, N. Jersey. *crispata.* *grisea.*

M. lacyi *Barn. & McD.* ♂ completely yellowish creamy, except the black base of the forewing, the last tarsal joint and a narrow fringe of hair around the eyes. Costal margin of forewing somewhat darker. A small brownish spot at the apex of the cell. Forewing covered with long curled hairs. The ♀ is more creamy white, otherwise similar to the ♂. Texas. *lacyi.*

M. affinis *Dcr.* The ♂ is completely creamy white, except a series of black scales along the costal margin of the forewing, fine blackish scales in the cell, and a black dot at the cell-end. ♀ unknown. Mexico, Yucatan. *affinis.*

M. ravidia *Drc.* (= *Archylus loanus* *Schs.*) (162 g). The ♂ has white legs, hindwings and abdomen, a slightly brownish thorax and head. Forewing more intensely marked brown in the basal area, especially in the cell, the exterior part of the wing marked feebly brownish. ♀ unknown. Mexico: Acapulco and Sinaloa. *ravidia.*

M. lapena *Schs.* (= *cyrtota* *Dyar*) (162 g). From brownish-white to creamy white. Basal part of forewing with a rusty brown or pale brown spot of curled hair, outside dark brown and interrupted by white. Mexico. — The Arizona-form of this species is — **heteropuncta** *Barn. & McD.*, in which the spot at the cell-end and the preapical spot of the forewing are small, punctiform and black; this deviation, however, is also often found in Mexico and may be merely a variation of the species. *lapena.* *heteropuncta.*

Cyclara-group.

Small, fragile species of which only scanty specimens are to be found in the collections. They must be ranged with *Megalopyge*, as the ♂ lacks the retinaculum.

M. obscura *Schs.* (= *Cyclara*). Wings light greyish brown. Forewing with a broad, diffuse, dark brown postmedian shadow partly edged with white. A black dot at the base, a subterminal black spot. French Guiana, also from Peru. *obscura.*

M. brunneipennis *Schs.* Body and wings dark golden brown. Forewing with a dentate whitish postmedian line from vein 5 to the inner margin; a subterminal dark brown dot. Rio de Janeiro. *brunneipennis.*

M. ovata *Schs.* (162 g). Thorax and abdomen greyish-brown, wings somewhat lighter. Forewing with a diffuse dark brown postmedian shadow, partly edged with undulate whitish lines; a black dot at the base; a subterminal black spot at vein 7. French Guiana. — The species resembles *Pod. guaya* *Schs.* in its marking and colouring, but it is much smaller. Mr. CARL HEINRICH, Washington, calls our attention to a difference in the neurulation: veins 7, 8, 9 of the forewing arise on a long stalk in *ovata*, on a short stalk in *guaya*. Future explorers will have to decide whether the genus *Cyclara* *Schs.* can be founded in this way. *ovata.*

2. Genus: **Podalia** *Wkr.*

P. orsilocha *Cr.* (*Bombyx orsilochus* *Cr.* = *vesta*, *dorsimacula* *Wkr.*) (162 g). The species varies in size, colouring and contours of wings, also slightly in marking. The ♀♀ exhibit a broad wedge-shaped white excision on the hindwing. Widely distributed, Guiana, West Colombia, South-Eastern Brazil. — Beside this nomenclatural race there are others occurring stragglingly. — **major** *Schs.* ♂ (163 a) shows the costal half of the hindwing white, the other half brownish; the ♀♀ are similarly marked. Venezuela, Central Colombia (Muzo), Peru (Chanchamayo). — **misantha** *Dyar* ♂ (163 a) shows all the veins of the hindwing lined brown. Mexico. *orsilocha.* *major.* *misantha.*

P. schadei *Schs.* (163 a) differs from *orsilochus* in both sexes in its shorter, more compact wings, the ♀ in completely brown hindwings containing only a small white zone before the dark brown edge of the distal margin. The ♂♂ have brown hindwings which are sometimes a little lighter in the basal area. Paraguay. It *schadei.*

is open to doubt whether it is a distinct species or only a form or race of *orsilocha*. Almost the same forms are besides at hand from Guatemala and Peru.

- albescens.* **P. albescens** Schs. ♂ (163 b). Lighter in all its parts than *orsilocha*. Hindwing white with brown marginal spots at the distal margin. Specimens occur with very dark forewings. Regarding the contours, the ♂♂ are almost intermediate between *orsilochus* and *schadei*. The ♀ is still unknown. South-Eastern Brazil: Minas Geraës, Rio de Janeiro, São Paulo, Sa. Catharina.
- fuscescens.* **P. fuscescens** Wkr. (= *megalodia* Dyar) (163 b) varies in size but little in colouring and marking. The ♀ has the same marking and colouring as the ♂. South-Eastern Brazil, also on the Amazons, the western coast of Colombia; probably its range extends still farther.
- walkeri.* **P. walkeri** Berg (= *Malmis* Dyar, *fieldia* Schs.) (163 b). This species has a different exterior in nearly every district of South-Eastern Brazil. The most extensively white are specimens from Sa. Catharina, whereas those from Minas Geraës exhibit but scanty white markings. Intermediary are specimens from São Paulo and Rio de Janeiro. The ♀ has the same colouring and marking as the ♂, but the hair along the costa of the forewing are white and curled. Argentine specimens (from Tucuman) are — **nigricostata** Dogn., they are blackish-brown, especially on the costa of the forewing. We figure another race from the Province of São Paulo — *semialba*, **semialba** Hopp (163 b). The tibiae and tarsi of all these forms have black and white ringlets.
- lanocrispa.* **P. lanocrispa** Jones (= *interlineata* Dyar) (163 c) is closely allied to *walkeri*, likewise with ringlets on the tibiae and tarsi. Forewing with pale yellowish lines between the veins, a dark postmedian line crosses the wing from vein 5 to the middle of the inner margin, but it is only indistinctly visible. The basal area with several black curled locks of hair which easily fall off. The ♀ does not differ from the ♂ in marking and colouring. Paraná and Minas Geraës, Brazil.
- tympania.* **P. tympania** Drc. (163 c) is an extraordinarily variable species, especially in the postmedian white marking of the forewing, the zig-zag lines of which may be centred black or almost quite extinct. Base and costa of forewing broadly white, with black veins, vertex white or yellow. Thorax blackish-brown, abdomen somewhat lighter. Legs with long white hairs on one side. Tibiae and tarsi brown. ♀ with the same colouring and marking as the ♂. Widely distributed from Mexico to Peru, on the Amazon R., in Colombia, Guiana.
- nivosa.* **P. nivosa** Jones (163 c) is allied to *tympania* and represents it in South-Eastern Brazil. Femora with long white hair on one side, tibiae and tarsi blackish-brown. The species looks like a *Meg. albicollis* with very intensely white markings. ♀ unknown. Paraná and Minas Geraës.
- mallas.* **P. mallas** Drc. (= *Bedalia corops* Dyar) ♂ (163 c). The blackish-brown forewing exhibits a broad white costa, a black basal and cellular spot and a narrow white transverse median line extending almost to the inner margin. Hindwing brown. Head blackish-brown, white around the antennae. Thorax, abdomen and legs blackish-brown, the legs with long white hair on the femora. Basal half and more of the forewing with curled hair. ♀ unknown. Minas Geraës, Paraná, Rio de Janeiro, Sa. Catharina.
- vicina.* **P. vicina** Hopp ♂ (163 c) differs from *Mallas* in the white thoracal tuft, lighter hindwings and another direction of the shorter, broader, median white mark on the forewing, which extends below the cell towards the interior angle and is composed of curled white hair. Differences in the sexual armature have also been ascertained. ♀ unknown. From Itatiaya, also from Villavicencio, Colombia.
- intermaculata.* **P. intermaculata** Dogn. This species, very similar to *vicina*, shows the median white spot on the forewing divided into two finely split parts, the lower one hollowed out outwards, prolonged, almost to the inner margin. According to HEINRICH, this species also shows differences from *vicina* in the male sexual armature. ♀ unknown. South Peru, Eastern Bolivia.
- angulata.* **P. angulata** Hopp ♂ (163 d). The median white spot of the forewing is almost triangular here and is not composed of curled but of smooth hair. All the white is interrupted by black veins. ♀ unknown. Macas, Ecuador.
- gamelia.* **P. gamelia** Drc. ♂ (163 d). Excepting the blackening of the costal region of the forewing, all the brown markings are broken up into spots. ♀ unknown. Peru, Guiana, Western Coast of Colombia.
- pedacia.* **P. pedacia** Drc. ♂ (163 d) has a black head, collar, abdomen and legs. The tegulae are grey, the anus and underside of the abdomen white. Antennae ochreous. The marginal spots of the hindwing are variably developed. ♀ unknown. Peru, Carabaya.
- pedacioides.* **P. pedacioides** Dogn. Antennae of ♂ with a white shaft and greyish-black pinnae. Thorax blackish-grey, tegulae blackish-grey, edged with white. Forewing with a narrower white distal margin than in *pedacia*, the marking about midway between *pedacia* and *pseudopedacia*. Colombia: Tolima.

P. pseudopedacia Dogn. ♂ (163 d). Antennae brownish ochreous, very broadly pinnate. Head and body white, mixed with grey, abdomen above predominantly grey like the legs. Wings somewhat hyaline. The author states besides that vein 6 of the hindwing is nearer to 7, while in *pedacia* and *pedacioides* it is about midway between 5 and 7, but this mark is probably variable, for it occurs also that veins 6 and 7 arise on a short stalk. The ♀ is not different in marking and colouring. A remarkable fact is that, contrary to other *Megalopyginae*-♀♀, vein 8 of the hindwing in the ♀ extends in exactly the same way as in the ♂♂, except that it anastomoses in the basal part with the anterior edge of the cell. Colombia: Bogotá. *pseudopedacia*.

Contigua-group.

P. contigua Wkr. (*Alpis*) (= *Bombyx habitus* Edw.) ♂ (163 d) is extremely variable in size and colouring. We figure a specimen which corresponds most to the description of the type (the type itself seems to be lost). Mexico, Guatemala, Costa Rica, Panama, Colombia, Ecuador, Peru. — **montana** Schs. (163 e) is a form with a lighter distal margin. We figure a most contrasting specimen, though all kinds of transitions between these two colourings occur. It is to be found wherever *contigua* itself occurs. *contigua*. *montana*.

P. salacia Drc. (163 e) differs in its more reddish-brown instead of dark brown colouring, and besides in the almost straight distal margin of the forewing, which is distinctly convex in *contigua*. Costa Rica: Irazu. *salacia*.

P. cirrata sp. n. (163 e) differs from *contigua*, *montana* and *salacia* in the distinctly curled hair of the dark brown basal area pierced by light veins. The transverse light line is scarcely visible. Abdomen, thorax, legs light brown, head somewhat darker. Hindwing even somewhat lighter than the broad distal margin of the forewing. The distal-marginal line in both wings, which is interrupted by the veins in the other species, is entirely absent here. Peru: San Domingo, Carabaya (G. OCKENDEN). Type in the Tring Museum. The type has much longer, more pectinated antennae than the specimens at hand of the other species of this group. *cirrata*.

Not one ♀ of all the species of the *contigua*-group has become known so far.

Dimidiata-group.

This group comprises four closely allied species which are rather variable individually and occur in most different districts; they can be distinguished from each other by certain marks in the male and female sexual form.

P. dimidiata H.-S. (*Limacodes dimidiatus* H.-S. = *Meg.* [*Gois* Dyar] *nigrescens* Schs., *Cyclara* [*Repnoa* *dimidiata* Dyar] *amarga* Schs., *Meg. farmbri* Kaye) (163 e) is variable in the veins, size, colouring, and marking. It has a wide range: Mexico (Tabasco) as far as Sa. Catharina and Peru. The species is discernible from the others by its thin, fragile body inclusive of the thinly scaled resp. hairy wings, and the specimens are smaller on an average and have narrower wings. The colouring of the basal area of the forewing is from dark brown to black and more extensive at the distal margin, generally leaving only a small part of the apex free, which is light brown or white. Hindwing in both sexes blackish hyaline, with a narrow light distal margin.

P. thanatos Schs. (163 f). The dark basal area of the forewing is lighter below the cell and terminates distally in pointed zigzag curves which are edged white outside. Hindwing from light brown to whitish, fringe blackened at the distal margin, more rarely at the inner margin. The ♀ is much darker, the hindwing as well as the distal margin and apex of the forewing are pierced by light veins; therefore also the white edging of the basal area of the forewing is more distinct. Guatemala, Costa Rica, Venezuela, Guiana, Colombia, Peru, but not observed in South-Eastern Brazil. *thanatos*.

P. arpi Schs. (163 f). The border between the black basal area and the light brown distal-marginal and apical part of the ♂ forewing is irregularly dentate, but not in distinct zigzag curves, though it is also edged with white distally. A vertical row of cloudy dark spots in the distal-marginal area. Hindwing light, blackish at the base and inner margin. ♀ similar to the ♂, rather thinly scaled and similar to *dimidiata*-♀ from which, however, it differs in the broader light distal margin of the forewing, especially near the angle. South-Eastern Brazil: Minas Geraës, Rio de Janeiro, on the Itatiaia, São Paulo, Sa. Catharina. *arpi*.

P. walkerensis nom. nov. (= *dimidiata* [Ocha] Wkr. is preoccupied by *dimidiata* H.-S.) (163 f, g). The species is about midway between *thanatos* and *arpi*. ♂: the light distal margin of the forewing near the angle is marked with pointed black spots, so that a white zigzag line is produced. Hindwing intensely blackened at the inner margin. ♀: hindwing similar to *thanatos*, forewing distinctly defined light brown in the apical *walkerensis*.

and distal-marginal areas, with a vertical row of blackish, outside white spots. Observed in Costa Rica, Colombia (Western Coast), Peru, Minas Geraës (Uberaba), Rio de Janeiro, and on the Itatiaya.

Cincinnata-group.

Three closely allied and similar species, but easily discernible by certain marks.

cincinnata.

P. cincinnata Dogn. (163 g). The type of the Washington Museum is in an extremely bad condition, the abdomen does not belong to the specimen, but according to HEINRICH it proved to be that of a Noctuid. Nevertheless, the species can be reconstructed by aid of a ♂ of the Tring Museum, originating from Bolivia like the type. The dark brown basal area with an indistinct black cellular spot consists of curled hair. It is distally bordered by an indistinct whitish vertical line which widens much towards the apex at vein 5 and contains several blackish streaks between veins 5 and 9 on the whitish area. The distal margin of the forewing is otherwise brown, the veins are somewhat darker. The contours of the distal margin are almost straight. Hindwing brown, with blackish veins. ♀ unknown. Bolivia.

proiecta.

P. proiecta sp. n. (163 g). The dark brown basal area of the forewing, broadly darkened at the costa, is composed of short scales. It is pierced outside from the inner margin to vein 5 by white veins and followed by an indistinct whitish vertical line and, from there to the costa, it runs back inwards roundish, likewise with an indistinct white zone outside. The distal margin is distinctly convex. An apical black spot on vein 7 in the light distal-marginal area, and an indistinct row of dark spots from the angle to vein 5. Hindwing light brownish, somewhat darkened at the inner margin. ♀ unknown. Peru, Carabaya (OCKENDEN). Type in the Tring-Museum.

guaya.

P. guaya Schs. (163 g). The dark brown distal-marginal area of the forewing with an indistinct cellular spot is formed of curled hair. It is bordered outside by an indistinct, costally more inward whitish vertical line which widens much at vein 5 towards the apex and contains four oblong black spots between veins 6 and 9. The distal margin is distinctly convex. The distal-marginal area is slightly covered with brown curled hair which is not to be found on the two other species. Hindwing whitish. ♀: forewing completely covered with curled hair, the white postmedian line is outwardly dentate in the inner-marginal part. Hindwing dark brown. Minas Geraës and Paraguay. — The species varies much in size, but its marking and colouring is constant in long series.

bolivari.

P. bolivari Heyl. (*Pentophera*) (= *Meg. pellucens* Dogn., *Unduzia gistinda*, *phaule* Dyar) (163 g). The species differs extraordinarily in the male and female sexes also in its external appearance. The ♂ is quite black, the wings hyaline, without any markings, with a black costa. ♀ considerably larger, from light brown to dark brown, head, thorax, abdomen and legs greyish brown, wings semihyaline, the forewing with a vertical postmedian row of whitish spots. Mexico, Panama, Colombia, Venezuela, Peru.

dyari.

P. dyari Joic. & Talb. Only the ♀ is known. It is much larger than *bolivari*-♀, blackish hyaline like the ♂ of *bolivari*. The black thorax bears two tufts of purely white hair in front and a small one at the base. The wings are longer and narrower than in *bolivari*. The forewing exhibits one small heap of white scales each between the veins 5, 6 and 7, near the base. Legs black, beneath with a distinctly defined row of white hair. Ecuador.

III. Aidinae.

The male *Aidinae* are provided with broadly plumose antennae feebly dentate in the terminal parts, while the antennae of the ♀♀ are thicker, plain in the basal parts, thinner and feebly dentate in the terminal parts. In both sexes, the precostal vein of the hindwing extends freely and is connected at most with the cell by a cross-vein. The cross-vein is situate more basad in *Aidos* and therefore smaller, or entirely absent, while in *Xenarchus* it extends obliquely forward to the precostal vein and is somewhat longer thereby. The *Aidinae* are more specialized by these characters than other *Megalopygidae*. The organisation of the appendages of the 10th ventral segment in the ♂♂ approximates *Trosia* with which they are also allied by the red colouring, but also the Mediterranean genus *Somabrachys* the larvae of which may be allied to those of the *Aidinae*. For the flat dorsal and subdorsal foveae of the larval ventral segments, on the bottom of which there are two rows each of divaricating short bristles, remind us of the skin-bags subdorsally developed in the larvae of the *Somabrachys*, which are filled with loose bundles of short black-hyaline spines. In the neuration, the *Aidinae* differ besides from the other *Megalopygidae* in the posterior half of the cell of the hindwing being produced into a long point terminating into veins 3—4 near which also vein 5 arises. This formation reminds us of some *Lima-codidae* to which several authors formerly placed the *Aidinae*.

All the species are interrelated, some of them are extremely variable in size and colouring. About the biology we have already spoken in the introduction to the family.

1. Genus: **Aidos** Hbn.

Aidos Hbn. (= *Brachycodion* Dyar). The characters of the genus have been mentioned in the introduction.

A. amanda Stoll (164 a). Very variable in size and colouring, widely distributed: Mexico, Guatemala, *amanda*, Panama, Colombia, Venezuela, Guiana, on the whole of the Amazons, Ecuador, Paraguay, South-Eastern Brazil. The species is easily discernible from all the others by the hindwing showing blackish veins which are conspicuous at least in the costal part of the wing. The forewing is divided by brown and whitish scales into broad transverse bands which partly show an outward black pointedly dentate edge, though the bands become indistinct according to the predominance of the brown or whitish scales. Under surface brown or whitish with brown veins. Hindwing generally broad red only at the inner margin; the red colouring is more extensive in Mexico where also ♀♀ with an orange-basal area occur.

A. yamouna Dogn. (164 a) has uniformly red hindwings, while the forewings are brown, strewn with *yamouna*. white in the costal centre of the cell, with a darker zone beyond the cell. Wings beneath red, the costal and apical districts broadly greyish brown. Loja, South Ecuador. — The species thus represents only an extreme form (hindwing without any brown), whereas other forms are partly farther distributed. — **nuncilla** Dogn., *nuncilla*, from Colombia (Tolima), is discernible from it by the interspersation of black scales on the hindwing. In — **cynosura** Dogn. (164 a) the distal margin of the hindwings is brownish or with a black streak at the angle, while the ♀♀ are red only in the basal area, the distal half being brown. The colouring of the forewings varies considerably between whitish and brown. Colombia, Amazons, Peru, Bolivia. *cynosura*.

A. perfusa Schs. (164 a) is recognizable by the whitish-yellow basal area of the forewing extending to *perfusa*. the cell and exhibiting an oblong black spot at the base of the costa, a roundish one before the inner margin. The distal margin is broadly blackish brown, interrupted by an indistinct whitish line. Hindwing red, with a broad blackish brown distal margin. Thorax whitish, suffused with brown in the middle. Abdomen red, with a narrow blackish dorsal zone. The red colouring varies between light pink and dark red, the brown colouring between light brown and blackish-brown. Both wings beneath red on the basal halves, whitish grey on the distal halves. The form — **admiranda** Schs., from Costa Rica, is merely a variation of the species. Widely distributed: Costa Rica, Panama, Colombia, Guiana, Venezuela, Ecuador, Peru, throughout the Amazons. *admiranda*.

2. Genus: **Xenarchus** H.-S.

Xenarchus H.-S. (= *Brachycodilla* Dyar). Cf. the introduction.

X. osorius H.-S. (= *Aidos castrensis* Schs.) (164 b). ♂. Forewing similar to *amanda*, but with a distinct *osorius*. white vertical streak at the angle. Hindwing white, red at the inner margin, with a row of blackish dots at the distal margin and blackish fringe. However, there are also ♂♂ the hindwings of which are coloured exactly like the ♀♀ (gynomorphous form). The hindwing of the ♀ is broader red at the inner margin, brownish elsewhere, especially at the angle and costa. South Brazil.

X. carmen Schs. (164 b). ♂. Forewing with a semicircular row of small black spots beyond the middle, *carmen*. a small white vertical streak at the angle. Hindwing red with a greyish-brown apex and fringe. ♀. Forewing without the semicircular line of black spots or only with traces of them. Hindwing more extensively red than *osorius*, broadly brown only at the costa, otherwise very similar to *osorius*. South Brazil.

X. admirabilis Schs. (164 b). ♂. Forewing yellowish white with a red and blackish marking, beneath *admirabilis*. mostly of a bright cerise colour. Hindwing white. ♀ unknown. South Brazil, also from Paraguay.

17. Family: Limacodidae.

In Vol. XIV, p. 447, where the denomination of the family was already largely dealt with, it was also pointed out that these most abnormal lepidoptera represent a phylogenetically old family. At any rate, they are quite homogeneous in the structure of the body, and we know but few other families exhibiting such a great homogeneity even in quite remote continents. Considering the entire absence of a proboscis together with the often monstrously developed palpi, the origin of the family presumably dates back to the times when the phanerogamic plants secreting honey did not yet play any part in the vegetation of the earth, for the *Limacodidae* have no ecological relations whatever to melliferous blossoms.

Another fact in favour of this phylogenetic age is their distribution over the earth. In Australia being a most ancient part of our globe they form an important part of the lepidopteral fauna and are especially distinguished by a relatively great number of forms as well as by large-sized representatives. By the predilection of many species for the *Eucalyptus* which is most widely distributed in Australia they appear to be especially adapted to that continent; but it is a remarkable fact that they are entirely absent in New Zealand which country, however, is at any rate very poorly supplied with Macrolepidoptera. On the other hand, their number is rather small in the neotropical regions which are so abundant in modern lepidoptera, even if we consider that thorough anatomical examinations will yield quite an increase of other Tropical-American species belonging to this family. There are about 20 species occurring in the boreal parts of America, and 35 inclusive of its southern confines, and even as many as 50 species, if all the forms that have not yet been thoroughly examined prove to be distinct species. In contrast with this relatively large number, the whole neotropical region of America does not even harbour 300 well distinguished forms. North America is also well supplied with species compared with Europe where only 3 species occur which are besides very inconspicuous in the palaearctic lepidopteral fauna. This share of Europe is extraordinarily small considering the total number of about 1000 Limacodid species.

The general characters have already been largely dealt with in the Volumes 2, 10 and 14. We merely remind the reader of the most distinctive marks characterizing the family: the roundish shapes of the body in all the stages, the creeping sole of the larvae which are frequently provided with nettle-organs, the almost invariably oviform cocoon, the strange metamorphosis of the larva evinced by the stage of a preliminary pupa, the emergence of the imago after detaching a lid-shaped plug from the paper-like web. The anatomical details are specially mentioned in each of the genera.

Considering the very old age of the family, the extraordinary homogeneousness of all the *Limacodidae* known to this day is rather striking. Nowhere, not even in America which otherwise exhibits such multifarious shapes, are we met with extravagantly developed forms of the imagines, whereas the larvae exhibit various peculiarities for protective reasons. We have frequently pointed out the gall-like exterior of numerous Limacodid larvae which often cling to the leaves or stalks of the food-plant like a tumour or a parasitic formation, and quite a number of American Limacodid larvae show even a modification of this adaptation to a fruit or gall by their strikingly copying a nibbled place on this formation: the larva of *Prolimacodes scapha* from North America, for instance, represents a green fruit from which a piece has been bitten out above, so that the red flesh of the fruit appears. In a very similar way the larva of *Tortricidia testacea* Pack. exhibits a red dorsal spot looking like the red sap emanating from a nibbled green berry. The strangest phenomenon, however, not only of all the lepidoptera but almost of the whole animal kingdom, is the female imago of *Phobetron hipparchia* Cr. in its repose, exhibiting small roundish yellow spots on the reddish ground of the forewing and quite similar small round hair-pads on the feet and the articulations of the legs. The imago settles for its repose on the surface of a green leaf in such a way that it spreads the very long legs of one side far out and, in a way, hangs on them, whilst it draws in those of the other side so that the yellow articular tufts join the orange spots on

the wings, whereby the contours of the lepidopteron are totally changed. Thus it seems as if some quite amorphous object were lying on the leaf, something like a tuberous fruit or a half-masticated raspberry some seeds of which are scattered around the remainder of the fruit. The larva of this strange very sexually dimorphous lepidopteron is no less curious; it is the South-American generic associate of *Phobetron pithecium* which is widely distributed in the Atlantic states of the U.S.A. and well known as the "monkey-slug". One might rather take it for a flock of hair or a hairy spider than the larva of a lepidopteron. Its oval brown-haired body is covered with long fur-horns which look like the thick legs of a spider and are frequently held by the insect in such a way that two of these hairy formations on each side are pointing forward and two more hindward, so that the likeness of a small bird-spider is produced (cf. Vol. X, p. 666).

The family abounds in such unusual phenomena and is thereby especially distinguished from those groups of Heterocera which it seems to approximate morphologically, as for instance the *Zygaenidae*. Judging by the shape of the pupae, the *Limacodidae* probably originate from the same base as the *Zygaenidae*; in both the families the limb-cases are not firmly inserted into the trunk of the pupa, but independently developed and only loosely appressed (pupa libera). But whilst the *Zygaenidae* have been subject to a great process of adaptation during the most recent epochs, the *Limacodidae* have adhered to their original type; the objects copied by them for the sake of adaptation are old models — fruits, green leaves (genus *Parasa*), or spiders, whereas the *Zygaenidae* which are highly mimetic (in their subfamily *Chalcosiinae*) copy products of the most recent times, such as *Euploea*, *Danais*, Pierids and similar modern butterflies, from which fact we are able to conclude the epoch of their origin.
